# CHEMICAL ABSTRACTS

Vol. 28.

JANUARY 10, 1934

No. 1

## 1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Chemical equipment from acid-resisting concrete. N. Bernatzki. *Chem.* 5, 2960-9(1933).—Phys. and chem. properties of acid-resisting concrete compns. and their use in the constrn of chem. equipment are discussed. Chas. Blanc

Laboratory comminators. H. A. J. Pieters. *Chem. Weekblad* 30, 722-3(1933).—A changeable burner for regulating the distance of the burner opening to the crucible and a simple gaseous regulator are described. E. Schotte

Laboratory drain-trap. John L. Wilson. *Ind. Eng. Chem.* 25, 1216(1933)

Continuously-operated laboratory apparatus for high-pressure reactions. H. V. Smeets and H. Vollbrecht. *Chem. Fabrik* 1933, 4671.—Detailed description, with 8 cuts and 4 references of an app. designed for general experimentation. J. H. Moore

Design of dustop sinter. D. C. Simpson. *Ind. Eng. Chem., News Ed.* 11, 3-4(1933). E. J. C.

Uchida's new distilling flask to prevent bumping. S. Uchida. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 551-2(1933). Kari Kammermeyer

Improved form of mercury still. P. G. Nayar, Rao Narayanan, V. Venkat and B. Dasannacharya. *Indian J. Physics* 8, 113(1933).—An app. is described which allows the dist. of Hg without the use of an auxiliary pump. C. E. P. Jeffreys

Recording and predicting low humidity. A. C. Walker. *Instruments*, 184-6(1933).—App. are described. E. H.

The influence of surface tension on the reading of hydrometers. Berthold Scheda. *Chem. Fabrik* 1933, 413-14. J. H. Moore

New vacuum technique aids for chemists. W. v. Meyeren. *Chem. Fabrik* 1933, 409.—A small Gaede rotary oil pump and a Gaede manometer ("Vakuskop") are described with 3 cuts. J. H. Moore

Construction of a new high-vacuum gage. Fumio Yamazaki and Zzyugo Yoshida. *Proc. Phys.-Math. Soc. Japan* 15, 400-4(1933).—The range of the McLeod gage was extended to  $10^{-4}$  mm. by mounting a membrane differential manometer on the McLeod capillary tip. The small pressure difference between the gas compressed in the tip and the uncompressed gas is measured by magnifying the movement of the membrane with an optical lever. E. J. Rosenbaum

Simple vacuum tube oscillator for conductivity experiments. J. H. Saylor and J. M. A. Debruyne. *J. Chem. Education* 10, 703-4(1933). E. H.

Vacuum centrifugal pumps. Karl Grün. *Chem. Fabrik* 1933, 450-51.—Pumps that will handle mixts. of liquid and gas are described. Cf. C. A. 23, 4850; 27, 4443. J. H. Moore

The ultracentrifuge. J. W. Beams, A. J. Weed and E. G. Fickels. *Science* 78, 388-40(1933); cf. C. A. 27, 4901.—Details of construction are given of an air-driven type of ultracentrifuge which is simple and cheap, and with which centrifugal forces in excess of  $10^5$  gravity have been obtained. Modifications in construction to allow sepn. of solid, and the observation of the rate of sedimentation are described. Allen S. Smith

A new type of spring pipet for analytical purposes. Gunnar Sjuggren. *Z. anal. Chem.* 94, 240-7(1933).—

An instrument is described which has recently been placed on the market and serves for the accurate delivery of definite vols. of reagent. It can be used as an automatic pipet or as a buret. It is filled by the action of gravity from a bottle placed a little higher or by pressure from an atomizer bulb when the reagent is stored in a vessel placed beneath the pipet. The pipet is made to deliver its contents by pressure from a column of Hg. W. T. H.

Apparatus for microanalysis of gas. J. S. Swearingen, Otto Gerbes and E. W. Ellis. *Ind. Eng. Chem., Anal. Ed.* 5, 369-70(1933).—The method is based on the principles used by Blacet and Leighton (C. A. 25, 4816) but the app. is arranged for more convenient operation. J. H. Moore

New apparatus for microelectrolysis. Hermann Brantner and Friedrich Hecht. *Mikrochemie* 14, 27-9(1933).—The app. consists of an Al block, which is insulated by a sheet of heavy asbestos paper and is provided with 2 indentations for holding a thermometer and also the electrolyzing vessel. The app. can be heated with a flame and is provided with binding posts for elec. connection. The electrolyzing vessel is an unpolished Pt crucible which is covered with a glass bulb through which a second elec. contact is made and through which also the electrolyte can be withdrawn at the end of the electrolysis. The electrolyte can be kept at any desired temp. and there is no danger of loss by spattering. W. T. H.

Apparatus for precise viscosity measurement developed at Pennsylvania State College. Robert C. Conine. *Oil Gas J.* 32, No. 23, 17, 30(1933).

The efficiency of rectification columns. E. Kirchbaum. *Chem. Fabrik* 1933, 431-6.—Math., with 8 cuts, 11 graphs and 7 references. J. H. Moore

Investigations on rectification in packed columns. M. Weimann. *Chem. Fabrik* 1933, 411-18. J. H. Moore

Simplified micro-comparator. Wm. Stirling. *Anal. Chem.* 58, 684-6(1933).—The instrument which is mounted on a stand consists of a telescopic tube which draws out to one side giving it a range of 1 ft. In the center is a low-power eyepiece. At either end of the main tube, which is fitted with 4 specially paired prisms, depends an arm into which low-power magnifiers are fitted and these can be focused independently. The 2 halves of the field, viewed through a single eyepiece, appear in juxtaposition. Any objects such as seal impressions, typewritten letters, stamps, paper, textile fibers, wood, etc., can be compared easily and a photographic record made. W. T. H.

Gasometer with constant pressure. J. Lindner. *Mikrochemie* 13, 318-16(1933).—The gasometer consists of two 10 l. bottles, one above the other in an Fe framework. Communication between the bottles is accomplished by tubing which starts at the bottom of the upper bottle and ends near the top of the lower bottle so that the pressure depends upon the distance between these points which can be varied at will. A picture of the app. is shown. W. T. H.

The Steindorff polarimeter. K. Seiler. *Pharm. Zeit. Schw.* 3, 140-5(1933); cf. C. A. 25, 1121, 1122.—A criticism of this app. is given. It will sufficiently serve the needs required by Pharm. Inst. V. Certain (minor)

difficulties can be obviated by using a more active light filter.

**Apparatus for lactic acid determination.** Hans J. Fuchs. *Z. physikal. Chem.* 221, 271-7 (1933).—An app. is described for detn. of lactic acid by  $\text{KMnO}_4$  oxidation, and distn. and iodometric titration of the  $\text{AcH}$  formed. It is claimed to have certain advantages over the Friedemann-Cotton-Schaffer (C. A. 21, 2711) and the Lieb-Zacherl (C. A. 26, 5791) app. and to yield more nearly quant. values.

**Apparatus for subliming iodine.** R. Jacquemains. *Bull. soc. chim.* 53, 633-5 (1933).—A simple all-glass app. is described for obtaining pure, dry, sublimed I; wet or impure material is used as a starting basis.

**Apparatus for the continuous ether extraction of an aqueous solution.** Alfred Lemman. *Bull. soc. chim.* 53, 635-6 (1933).—The construction and operation of a simple glass extractor are given.

**Images of surfaces which reflect electrons in the electron microscope.** E. Ruska. *Z. Physik* 83, 492-7 (1933).—The magnetic electron microscope can be used to obtain images of objects which are too thick to transmit electrons but reflect a great part of the electrons under large angles and with small losses of energy.

**Images of metal foils in the electron microscope.** Bodo v. Borries and Ernst Ruska. *Z. Physik* 83, 187-93 (1933).—The magnetic electron microscope is applicable to the investigation of thin foils, if care is taken that the electronic beam has not only a small aperture when falling on the foil, but retains a small aperture after passing through it. This can be obtained by stopping scattered electrons by means of a diaphragm. The loss of velocity in the foil causes chromatic aberrations of the optical system.

**Gold-leaf electroscope.** J. Back. *Phil. Mag.* 16, 775-9 (1933).—A tilted electroscope is described which has, instead of a gold leaf, a phosphor bronze strip 0.0005 cm. wide, part of which is wound into a small spiral of about 6 turns. The axis of the spiral is perpendicular to the direction of displacement of the strip. This strip is less sensitive than a gold leaf but is much easier to mount, has a more uniform sensitivity and is less fragile.

**Sensitive photoelectric cells for red and infra-red.** W. Kluge. *Z. wiss. Phot.* 32, 142-4 (1933).—Measurements are shown for 3 cells the active surface of the Ag cathode of which is composed of  $\text{Cs}_2\text{O}$  having adsorbed to it an extremely thin film of Cs, in comparison with a pure Cs film cell.

**The development of the Röntgen tube in its significance for science and technology.** Walther Gerlach. *Chem. Fabrik* 1933, 219-26.—Historical, with 22 cuts.

**Progress in the design and manufacture of x-ray tubes.** M. J. Gross and Z. J. Atlee. *Radiology* 21, 365-77 (1933).—An outline is given of some of the factors which have been of importance in regards to x-ray tube construction and manuf. Problems of design include phys. dimensions, glass, gas and focal spot considerations. Under problems of manuf. details on assembling and exhaust and production tests are presented.

**Effect of tube diameter in cyclonic dust collectors.** Ewald Anderson. *Chem. & Met. Eng.* 40, 525-6 (1933).

**A new type of expansion apparatus.** C. T. R. Wilson. *Proc. Roy. Soc. (London)* A142, 88-91 (1933).—An expansion app. of new design is described in which the expansion consists of a definite pressure change followed by an increase in vol. as the temp. rises, rather than the usual method of a definite vol. change followed by an increase of pressure with the rise of temp. The new design is more easily constructed and is less restricted as to the dimensions and position of the cloud chamber than is the usual app.

**A multiform plastometer.** G. D. Lefcaditis and F. Avey. *Trans. Inst. Rubber Ind.* 9, 123-9 (1933).—The new plastometer which is described and illustrated, is so constructed that, by proper adjustment and manipulation,

the compression methods Williams (cf. C. A. 18, 1703; Martin, C. A. 25, 341) of van Rosse and van der Meijden (C. A. 22, 3048803), of Karrer, Davies and Dieterich (C. A. 24, 1544) and the hardness-elasticity method of Pusey and Jones, can be used, thus obviating several instruments. An app. feature is a revolving disk for preheating the sample.

**Pottery product for chem. wk., etc.** (U. S. 1,930,095) 19.

**Filters.** Christian Thon. *B.* 394,103, June 22, 1933. In app. comprising filter sheets, pockets, each suspended from an outlet pipe and having flexible distending means, the pockets are given a shake or vibratory movement to dislodge the cakes formed thereon.

**Filter suitable for laboratory use with "filtermass."** Lester E. Milkey (to Cellulose Co.). U. S. 1,930,209, Oct. 10.

**Leaf filters.** Henry Trent Thomas and Manlove, Alliott & Co. Ltd. Brit. 394,0 June 22, 1933.

**Rotary drum filter.** Morris Mount. U. S. 1,929,510, Oct. 10.

**Rotary drum filter.** Nels Bund (to Dorr Co. Inc.). U. S. 1,930,128, Oct. 10.

**Filter for liquids.** J. Samu White & Co. Ltd. and Arthur Hoare. Ger. 583,318, vt. 1, 1933. This corresponds to Brit. 361,681 (C. A. 1867).

**Filter for liquids.** Henri Luthier. Ger. 583,319, Sept. 1, 1933.

**Filter for liquids.** Jules Moud. Ger. 583,320, Sept. 1, 1933. Addn. to 448,346.

**Filter for liquids.** Eustace Alliott and Manlove Alliott & Co. Ltd. Ger. 584, Sept. 23, 1933. This corresponds to Brit. 338,510 (C. A. 25, 2335).

**Filter with candle-shaped elements for liquids.** Gustav Schlick. Ger. 584,284, Sept. 18, 1933.

**Apparatus for separating oil and water, etc.** Carl Billand. Ger. 583,447, Sept. 4, 1933.

**Filters and strainers, applic. for the removal of precipitates from salt solutions and impurities from oils, water or mercury.** The Thern Syndicate Ltd. and Burrows Moore. Brit. 394,042, June 22, 1933.

**Gas filter.** Ingenieur Hechekikner (to Chemical Construction Corp.). U. S. 1,924,6, Oct. 3. Numerous structural details are described.

**Apparatus for loosening square beds of granular material.** Paul Nitsch. Ger. 584, Sept. 20, 1933.

**Double filter plate for filter presses.** Meyer Wilderman. Ger. 583,317, Sept. 1, 1933.

**Flat circular filter for pot presses such as hydraulic cacao presses.** Max Michel. U. S. 1,930,903, Oct. 17. Structural features.

**Magnetic separators.** Herbert Hand Thompson and Alfred E. Davies. Brit. 388,868, June 9, 1933.

**Magnetic separators.** Darwin, Id. and Alfred C. Cathall. Brit. 389,920, Mar. 30, 1933.

**Magnetic separators.** Paul M. Lotti. Brit. 394,405, June 29, 1933.

**Magnetic separators.** Robert Forrer-Jaggi and Mines domaniales de potasse d'Alsace. Brit. 394,471, June 29, 1933.

**Jigging conveyors or separator.** Wm. J. Wallace. Brit. 394,503, June 29, 1933.

**Apparatus for separating components of different densities from flowing gaseous or liquid mixtures.** Eugen Haber. Ger. 583,261, Aug. 31, 1933.

**Apparatus for separating oil and gas.** Milton J. Trumble and Wm. L. Seeley (to Processco, Ltd.). U. S. 1,931,275, Oct. 17. Structural and mech. features of float-valve construction, etc.

**Apparatus for hydrating lime, separating lighter from heavier resultant particles, etc.** Wm. J. Kutz. U. S. 1,929,591, Oct. 10. Various structural mech. and operative details are described.

**Apparatus for separating materials of different densities, e. g., raw coal mixtures, of the jigging type.** Félian J. Meunier. Brit. 395,730, June 17, 1933.

- Vibration and air-current treatment for separating mixed materials such as those of "run-of-mine" coal Richard Peale and Rembrandt Peale, Jr. (to Peale-Davill Co.). U. S. 1,931,008, Oct. 17. Various details of an air-pervious table operation are described.
- Gravity-separation apparatus for washing granular materials. The Dorr Co., Inc. Brit. 395,222, July 17, 1933.
- Centrifugal separator for removing suspended particles from gases. George H. Horne and Marcus A. Lissman (to International Precipitation Co.). U. S. 1,930,806, Oct. 17. Structural features.
- Centrifugal bowls. Aktiebolaget Separator. Brit. 394,845, July 6, 1933.
- Device for drying centrifugal bowls. Aktiebolaget Separator. Brit. 395,021, July 20, 1933.
- Sifting apparatus for minerals, etc. Wm. A. Hiscor. Brit. 395,589, July 20, 1933.
- Apparatus for delivering measured quantities of liquids. Société d'étude de distributeurs automatiques S. E. D. A. Brit. 395,608, July 20, 1933. Addn. to 355,405.
- Surface condensers. Akt. Ges. Brown, Overi & Cie. Brit. 394,804, July 6, 1933; Ger. 583,057, Aug. 28, 1933.
- Surface condenser. Allmänna Svenska elektriska Aktiebolaget Ger. 583,058, Sept. 1, 1933.
- Temperature-regulating apparatus. I. Farbenind. A.-G. (Otto Eichenhut and Erich Kaup, inventors). Ger. 583,318, Sept. 1, 1933. In app. in which the demagnetization of a ferromagnetic material above a certain temp. actuates temp.-controlling device; the ferromagnetic material used is an alloy of Fe and Ni, e. g., an alloy contg. 8-11% of Ni.
- Apparatus for charging horizontal degassing chambers. Bamag-Megum A.-G. Ger. 583,114, Aug. 29, 1933.
- Gas-cooling apparatus operated with frozen carbon dioxide. Ernest Alvarez and André L. Jauphm. Ger. 583,263, Aug. 31, 1933.
- Apparatus for injecting liquid materials to gas streams as in treating natural gas with stenching material. Chester C. Ashley and Wm. I. Steele (to Shell Development Co.). U. S. 1,930,848, Oct. 17. A differential pressure-responsive device in communication with the gas stream serves to control the flow of liquid in accord with the velocity of the gas, and a static pressure-responsive device in communication with the gas stream adapted to maintain a predet. mass ratio of the injected liquid to the gas. Various details of app. arrangement are described.
- Apparatus for charging water with carbon dioxide. James Kantor (to Liquid Carbonic Co.). U. S. 1,929,948-9, Oct. 10. Structural and mech. features.
- Pressure vessel for carbonating liquids with solid carbon dioxide. A. Freundlich, Maschinenfabrik. Ger. 583,376, Sept. 2, 1933.
- Rotary mixing machines. John F. Wake. Brit. 394,449, June 29, 1933.
- Apparatus for mixing liquids. Akt.-Ges. Kuhnle, Kopp & Kausch and Karl Foerster. Ger. 584,234, Sept. 16, 1933.
- Mixing plant for pulverulent materials, provided with a sampling hopper fed simultaneously with the mixing hoppers. Mikael Vogel-Jorgensen. Brit. 394,484, June 29, 1933.
- Apparatus for mixing comminuted materials such as cement meal by forcing gas in the mixture. International Precipitation Co. Ger. 584,400, Sept. 15, 1933. This corresponds to Brit. 382,113 C. (A. 27, 4448).
- Apparatus for mixing dry comminuted solids. Jens K. F. Rannje. Ger. 584,333, Sept. 15, 1933.
- Rotary apparatus for contacting gaseous and non-gaseous materials as in mixers, gas driers. Sheldon B. Heath, Guy Cannon and Ormond A. Barstow (to Dow Chemical Co.). U. S. 1,930,751, Oct. 17. Various structural details of gas seals, etc., are described.
- Steam-heated tubular drier. Maschinenfabrik Buckau R. Wolf A.-G. Ger. 583,044, Aug. 28, 1933.
- Rotary drier for stone, gravel, etc. Colas Production Ltd., Augustus G. Terry and Laurence Briggs. Brit. 395,258, July 11, 1933.
- System and method for drying wood, impregnated articles, plaster, cement, liner, etc. Louis Gontier and Maurice Rougié. Brit. 394,112, June 22, 1933.
- Apparatus for drying fibrous, flaky or granular material. British Celanese Ltd., John E. Jones and David R. Johnston. Brit. 394,975, July 3, 1933.
- Separate heater and evaporator apparatus. Fischer Wym. Maschinenfabriken A.-G. Brit. 395,287, July 13, 1933.
- Spray evaporators for liquids holding solids in solution or suspension, e. g., malt extract, milk, gelatin. Wm. C. Mason and Wm. W. Hutcheson. Brit. 394,912, July 6, 1933.
- Crucible furnaces. Frederick S. Wigley and Joseph Wigley. Brit. 394,704, July 3, 1933.
- Removable cover for wide annealing furnace. Vereinigte Stahlwerke A.-G. Ger. 583,457, Sept. 4, 1933.
- Means for conveying annealing boxes through a furnace. Benno Schilde Maschinenbau A.-G. Ger. 583,111, Aug. 29, 1933.
- Means for igniting and controlling burners in a gas-heating apparatus "Gawa". Patent-Verwaltungs-A.-G. Brit. 395,565, July 20, 1933.
- Apparatus for heating air or other gases or vapors. Wm. A. Darrah. U. S. 1,929,881, Oct. 10. Structural and thermo-static control features.
- Lockable valve for gas burners. Henry Liva (one-half to Angelo Sebastianelli). U. S. 1,929,362, Oct. 3. Mech. details.
- Safety cut-off for gas burners operating when the flame is extinguished. Johan P. Franzen. U. S. 1,930,007, Oct. 10. Structural and mech. details.
- Adjustable boiler superheater. Wm. A. Jones. U. S. 1,929,532, Oct. 10.
- Heat-transfer surfaces for liquids. Paul Kleinewefers. Brit. 394,324, June 16, 1933. Structural features.
- Heating systems and apparatus. Max Winckler. Brit. 394,510, June 29, 1933. Steam from a superheater is continuously circulated by a pump through an oven, the steam being generated at starting solely in the superheater and the heat supplied thereto being sufficient to inhibit condensation during the circulation.
- Heat-exchange apparatus. Reuben N. Franc. U. S. 1,929,540, Oct. 10. Structural details.
- Heat-exchange apparatus suitable for use with liquids. Erik T. Linderöth and Curt F. Rosenblad (to Curt F. Rosenblad). U. S. 1,930,879, Oct. 17. Structural details.
- Heat exchanger (plate type). The Clyde Oil Fuel System Ltd. Ger. 583,123, Aug. 29, 1933.
- Serpentine tube heat exchangers. C. A. Parsons & Co. Ltd., Thomas Smith and Daniel C. P. Willis. Brit. 393,994, June 19, 1933.
- Tuyère block. Herbert R. Preston (to American Engineering Co.). U. S. 1,930,908, Oct. 17.
- Sintering apparatus. John E. Greenawalt. Brit. 395,619, July 20, 1933.
- Apparatus for estimating potassium by measuring its  $\gamma$ -radiation. Werner Kolhorster. Ger. 579,792, June 30, 1933. Addn. to 575,375 (C. A. 27, 3421).
- Röntgen-ray apparatus. I. G. Farbenind. A.-G. Brit. 395,578, July 20, 1933. In app. for radioscopic examn. 2 or more fluorescent screens producing fluorescence of different colors are arranged so as to be movable into operative position in turn. The screens may be composed, e. g., of Zn silicate, ZnS or BaPt(CN)<sub>6</sub>, or a mixt. of these, for 1 screen and CaWO<sub>4</sub> and (or) CdWO<sub>4</sub> for the other.
- Light-sensitive cells. Peter St. J. Heaton. Brit. 395,422, July 20, 1933. To minimize the effects of temp., humidity, age, etc., on Se and like cells the cell is subjected to a flickering light addnl. to the controlling light.
- Photoelectric cells. Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 395,049, July 13, 1933. A photoelec. cell is surrounded by a casing, the intermediate space being exhausted. The casing may be of reflecting material or of

translucent or transparent material, a part of the internal surface of which is silvered.

**Photoelectric cells.** Kenneth H. Kingdon and Hugh E. Thomson, (to The British Thomson-Houston Co. Ltd.). Brit. 695,220, July 13, 1933. A transparent light-sensitive layer is formed on a foundation member and transferred therefrom to the wall of the envelope. Thus a Cu washer is Ag plated and then oxidized by passing a high-frequency or d. c. discharge between the anode and the washer in O at 100  $\mu$ . Capsules contg. pellets of Cs dichromate and Si are heated to liberate Cs and form the layer on the washer and the bulb is baked at 300° and evacuated by the process of Brit. 303,176. The light-sensitive material is transferred to the envelope by cathodic sputtering, an a. c. or d. c. discharge being passed in A at 100  $\mu$ .

**Photoelectric cells.** Siemens & Halske A.-G. (Walter Schouky and Emil Duhme, inventors). Ger. 584,009, Sept. 13, 1933. In the manuf. of photoelec. cells in which a transparent electrode is deposited on a surface of  $\text{Cu}_2\text{O}$ , the  $\text{Cu}_2\text{O}$  surface is etched, e. g., with  $\text{H}_2\text{SO}_4$  of about 25% concn., before the transparent electrode is deposited.

**Photoelectric cell.** Westinghouse Elec. and Manufg. Co. Ger. 554,351, Sept. 18, 1933. See Brit. 291,763 (C. A. 23, 1019).

**Actinometer with a photoelectric cell.** Clarence T. Brewer (one-third each to Edward W. Menke and Harry L. Hillstrom). U. S. 1,931,283, Oct. 17. Structural, electrical and mech. details.

**Thermionic tubes.** The Mullard Radio Valve Co. Ltd. Fr. 750,640, Aug. 14, 1933.

**Thermionic valves with filamentary cathodes.** The Mullard Radio Valve Co. Ltd. and Baarte Krol. Brit. 395,439, July 20, 1933. Structural features.

**Electron tube.** Ulrich Doering (to Electrons, Inc.). U. S. 1,931,254, Oct. 17. An anode is assoc. with a heatable electron-emitting electrode adjacent which is a heatable positive ion-emitting body comprising a metal core such as Ni having embedded in it ionizable material such as Cs with a layer of another metal such as Co on the core to effect a controllable resistance to the diffusion of the Cs.

**Electron tubes.** Telefunken Ges. fur drahtlose Telegraphie m. b. H. Fr. 750,632, Aug. 14, 1933.

**Electron-discharge device.** Carl J. R. H. von Wedel (to Electrons, Inc.). U. S. 1,929,661, Oct. 10. A device such as an electron tube is provided with a cathode having an electron-emissive coating including an alk. earth metal compd., a non-emissive electrode carrying on it a compd. of a metal the oxy-acid of which is at least as acid as the corresponding acid of Pt, such as an oxide of W or Pt, and the electrodes may be surrounded by a gaseous medium.

**Discharge apparatus.** Egyesült Izzólámpa és Villamosági R. T. Brit. 394,982, June 30, 1933. An excess-voltage protective arrangement for low-voltage circuits comprises 1 or more gas-filled discharge tubes in which the electrodes are electrically connected with 1 or more thermal, e. g., bimetallic, switches, subject to heat generated by the discharge and short-circuiting the electrodes at a given temp., and wherein 1 or each of the mutually confronting electrodes, e. g., of Fe, contains a core of a more electropos. material to localize the discharge within the substantially enclosed space between them and to free the rare-gas filling from O and  $\text{H}_2\text{O}$  vapor. The electrodes may have axial bores which may be partially filled with an alkali or alk. earth metal or any electropos. compd. thereof, e. g., BaO.

**Electric discharge tubes.** Radioaktiengesellschaft D. S. Ioewe and Paul Kapteyn. Brit. 395,056, June 13, 1933. Structural and elec. features.

**Gaseous discharge device.** Heinrich Friedrichsen (to General Elec. Co.). U. S. 1,930,080, Oct. 10. Various structural details are described of a device of the neg. glow type which contains a gaseous atm. such as Ne and is provided with a cathode which may be formed of Al and which has an external wall carrying a thin coating of hydride such as  $\text{Al}(\text{OH})_3$ .

**Gaseous electric discharge device.** Martin Reger (to General Elec. Co.). U. S. 1,930,182, Oct. 10. Various structural and operative details are described of a device suitable for use with metal vapor such as Na.

**Gaseous electric discharge device.** Marcello Pirani and Martin Reger (to General Elec. Co.). U. S. 1,930,150, Oct. 10. In a device contg. mixed gases such as He and A or B and Hg vapor and the electrodes of which are connected to a d. c. source, the polarity of the current applied to the electrodes is changed at time intervals less than the time required for the sepn. of the gas mixt. noticeably affect the color of the light emitted. U. S. 1,930,147-49 (Marcello Pirani to General Elec. Co.) relate to structural details of elec. discharge devices.

**Gaseous electric discharge device suitable for use with metal vapor fillings.** Georg Gaidies (to General Elec. Co.). U. S. 1,930,090, Oct. 10. Structural features, use of particular kinds of glass, etc., are described.

**Cathodeless discharge tubes.** Compagnie française pour l'exploitation des procédés Thomson-Houston. Fr. 750,570, Aug. 12, 1933.

**Cathodeless discharge tubes.** Oskar G. m. b. H. Komm-Ges. (Hans J. Spauner and Ulrich W. Doering, inventors). Ger. 584,352, Sept. 18, 1933. Details are given of a construction of cathode in which an alk. earth zincate, aluminate or zirconate constitutes the electron-emitting layer.

**Device for detecting noxious gases in the atmosphere.** Arturo Imbato. Brit. 395,149, July 13, 1933.

**Apparatus for detecting smoke or dust.** Walther & Cie. A.-G. Brit. 341,853, July 6, 1933.

**Apparatus for oxidizing smoke, etc., with air.** Arthur O. Higginbotham (one-half to Wm. A. Weigle). U. S. 1,929,493, Oct. 10. Structural and mech. features.

**Hydraulic apparatus for compressing air.** Robert C. Wilson. Brit. 350,091, July 13, 1933.

**Gas-pressure regulating valves.** George A. Williams. Brit. 395,275, July 13, 1933.

**Pressure gauge of the general manometer type.** G. Cusson, Ltd. and Geo. W. Cussons. Brit. 395,399, July 17, 1933.

**Pressure-regulating valves for maintaining constant a slight vacuum in the conduit by which gases are withdrawn from a ionizing plant.** Bernard R. Parkinson and Parkinson & Cowan (Gas Meter) Ltd. Brit. 395,443, July 20, 1933.

**Liquid meter having two measuring chambers.** Joseph J.-M. Gueux. Fr. 394,558, June 29, 1933.

**Baffle-plate assembly for gas scrubbers.** Standen L. Pearce (one-half to London Power Co. Ltd.). U. S. 1,929,712, Oct. 10. Structural details.

**Storage tanks for gases and volatile liquids.** John H. Wiggins. U. S. 1,930,492-4-5, Oct. 17. Structural features.

**Receptacle for retaining liquefied gases, etc., under pressure.** Philip Mulvey. U. S. 1,929,511, Oct. 10. Structural features.

**Apparatus for partitioning flowing fluids such as in reheating steam.** Wm. E. Hannum (to Bailey Meter Co.). U. S. 1,930,055, Oct. 10. Various structural and operative details are described.

**Valve for corrosive liquids.** Fred L. Haushalter (to B. F. Goodrich Co.). U. S. 1,931,320, Oct. 17. Structural features are described of a valve with a rigid casing through which a collapsible conduit extends which may be formed of soft rubber operated on by a pinching device.

**Apparatus for measuring cellular products from fused materials.** Wilhelm Rixinger. Ger. 683,470, Sept. 4, 1933.

**Electrical apparatus for indicating the moisture content or consistency of material such as concrete aggregates.** George E. Webb (to Lechring Co.). U. S. 1,930,831, Oct. 17. Various structural, mech., electrical and operative details are described.

**Apparatus for proportional supply of materials such as acids in accord with electrical conductivity tests.** Eugene

D. Doyle (to Leeds & Northrup Co.). U. S. 1,980,353, Oct. 10. Various mech. and electrical features are described.

Apparatus for purifying gases and vapors—such as in purifying gasoline vapors with copper oxide. Milton J. Trumble and Wm. L. Szeley (to Processco, Ltd.). U. S. 1,929,659, Oct. 10. Various structural and operative details are described.

Seal for floating decks of tanks for storage of liquids such as petroleum oils. Frederick G. Hampton (to Standard Oil Co. of Calif.). U. S. 1,930,953, Oct. 17. Structural features.

Settling tanks. Leonard Andrews. Brit. 395,728, July 21, 1933. After each withdrawal of sludge from the bottom of a settling tank a portion of the sludge is forced back so as to loosen aggregated matter in the lower part of the tank and facilitate its subsequent removal.

Mercury boilers. Anthony J. Nerad (to The British Thomson-Houston Co. Ltd.). Brit. 392,783, May 25, 1933. In a Hg boiler means are adopted to ensure that the Hg wets the generating surfaces. The Fe or steel tubes are cleaned by pickling or mech. means or exposed to H for a few hrs. at 950° which decarbonizes the steel to an appreciable depth. When the heat-transfer surfaces are

cleaned prior to putting the boiler into use they are maintained clean by a coating of a suitable material that prevents their oxidation. The surfaces may be cleaned by adding Na or K, e. g., 0.25% to the Hg. NaOH may be used, the resulting H<sub>2</sub>O and H being removed by an air pump. Metals having a greater affinity for O than Fe, e. g., Zn, Sn, may be added to the Hg or the boiler may be coated initially with Zn or Sn.

Crushers with vibrating jaws. Fried. Krupp Grönsonwerk A.-G. Brit. 394,913, July 6, 1933.

Impact pulverizers. Leo St. J. Colley. Brit. 395,788, July 27, 1933.

Impact pulverizers for reducing grain. Elemér Zathureczky. Brit. 394,478, June 29, 1933.

Ball or tube mills. Humboldt-Deutzmotoren A.-G. Brit. 394,500, June 29, 1933.

Lightning arrester. Ted E. Foulke (to General Elec. Vapor Lamp Co.). U. S. 1,930,088, Oct. 10. An envelope contg. a gaseous atm. such as Ne, He and A under a pressure of about 25–45 mm. Hg also contains Ra and is provided with electrodes at least one of which carries Rb.

Automatic water-control valve for high-pressure acetylene generator. Wilhelm J. Herbst. Ger. 583,416, Sept. 2, 1933.

## 2--GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L BROWN

Henry Howard Salmon W. Wilder. *Ind. Eng. Chem.* 25, 1209 (1933). Biography with portrait.

A century of progress in chemistry. Arthur B. Lamb. *Science* 78, 371 6 (1933).

Alchemists in art and literature. Richard B. Pilcher. *J. Oil & Colour Chem. Assoc.* 16, 318 52 (1933). Lecture.

Knowledge of the metals in ancient India. R. N. Bhagvat. *J. Chem. Education* 10, 659 66 (1933).

Doctorates in chemistry and related fields conferred by American universities, 1932–33. Clarence J. West and Cilla Hull. *J. Chem. Education* 10, 693 703 (1933).

Class exercises in the industrial chemistry course. I. Topic reports on literature surveys. Kenneth A. Kobe. *J. Chem. Education* 10, 679 81 (1933).

Story of the scientific section of the educational bureau. Frederick G. Weed. *Paint, Oil & Chem. Rev.* 95, No. 19, 36 7, 82 (1933).

A new periodic chart. John D. Clark. *J. Chem. Education* 10, 675 7 (1933). Some advantages of a flattened spiral arrangement are pointed out.

Special exercises for students in general chemistry. II. Electrochemistry. G. Bryant Bachman and J. K. Farrell. *J. Chem. Education* 10, 689 90 (1933).

The story of zinc. II. H. W. Hanley. *J. Chem. Education* 10, 682 8 (1933); cf. *C. A.* 27, 5225. E. H. The fractionating column in the preparation of acetone. G. Ross Robertson. *J. Chem. Education* 10, 704–5 (1933).

Measurement of colors and its industrial applications. René Toussaint. *Mém. compl. rend. soc. ing. civils France* 85, 743 68 (1932).—An address.

Chemical information periodicals. Necessity of an international organization. C. Marie. *Chimie & Industrie Special No.*, 1255–6 (June, 1933).

The 1931 I. C. I. standard observer and coordinate system for colorimetry. Deane B. Judd. *J. Optical Soc. Am.* 23, 359–74 (1933).—This report gives in convenient form the properties of the standard observer recently recommended for colorimetric use by the International Commission on Illumination. These data supersede the 1922 report known as the O. S. A. excitation data. Formulas are given for computing trilinear coordinates

(trichromatic coeffs.), dominant wave length, colorimetric purity and luminous transmission (or reflectance) from spectrophotometric data. Tables of the data needed are included for the 1931 I. C. I. standard illuminants A, B, and C. Equations are given for interconverting O. S. A., Abbot-Priest and Davis-Gibson sunlight values.

Delivery of heat and temperature distribution of electrically heated wires. A. Farkas and H. H. Rowley. *Z. physik. Chem.* B22, 335–43 (1933).—Discontinuities in the pressure-temp. curves of electrically heated Ni and Pt wires as found in the para-H conversion are not due to surface conditions as previously supposed (*C. A.* 26, 377). The explanation lies in the lack of temp. equil. along the wire which arises if the H. Busch stability conditions are not fulfilled (*Ann. Physik* [4], 64, 401 (1921)).

The atomic mass of sodium. II. The sodium chloride-silver ratio. Clyde R. Johnson. *J. Phys. Chem.* 37, 923–33 (1933).—Using the improved methods outlined in this and in previous articles (cf. *C. A.* 26, 4551), J. detd. by means of titration analyses the ratio NaCl:Ag and gravimetrically the ratio NaCl:AgCl. If Cl = 35.457 and Ag = 107.880 the at. mass of Na as derived from both sets of expts. is 22.994.

A revision of the atomic weight of indium. Gregory P. Baxter and Chester M. Alter. *J. Am. Chem. Soc.* 55, 1943–6 (1933).—InCl<sub>3</sub> and InBr<sub>3</sub> were synthesized from electrodeposited In. From the ratios of these compts. to Ag the at. wt. was detd. nephelometrically as 114.76.

A revision of the atomic weight of thallium. The analysis of thallous chloride. Gregory Paul Baxter and Joseph Smith Thomas. *J. Am. Chem. Soc.* 55, 2384–7 (1933).—An at. wt. of 204.40 was found for Tl by nephelometric comparison of TlCl with Ag. Cf. *C. A.* 25, 1715; 26, 910.

A revision of the atomic weight of arsenic. The comparison of arsenic trichloride with iodine pentoxide. Gregory P. Baxter and Wm. E. Shaefer. *J. Am. Chem. Soc.* 55, 1957 63 (1933); cf. *C. A.* 27, 2356. The at. wt. of As was found to be between 74.906 and 74.916 from analysis of As<sub>2</sub>O<sub>3</sub>, which was dissolved in NaOH soln. and treated with a nearly equiv. wt. of I<sub>2</sub>O<sub>5</sub>. After neutralization with phosphate solns. the end point was found with 0.01 N I<sub>2</sub> and As<sub>2</sub>O<sub>3</sub> solns.

Certain relativistic aspects of the conception of chemical species, element and valence. E. Briner. *Rev. gén. Sci.* 44, 506–12 (1933).—A review pointing out the diffi-

culty of establishing a rigid definition of any one of these, and calling attention to the large no. of chem. species that must be considered. **Gregg M. Evans**

**Magnetic properties of iodine in different solvents.** S. S. Bhattacharya and C. I. Lakra. *Indian J. Physics* 8, 43 7(1933).—The magnetic susceptibility of I in  $C_6H_6$  =  $-0.51 \times 10^{-6}$ , in cyclohexane =  $-0.36 \times 10^{-6}$ , and in  $CS_2$  =  $-0.50$  to  $-0.51 \times 10^{-6}$ . These values favor the idea that I is ionized in  $C_6H_6$  and  $CS_2$ , and unionized in cyclohexane. **C. E. P. Jeffreys**

**Magnetic study of manganese sulfate and some rare earths.** S. Valayos. *Anales soc. españ. fis. quim.* 31, 597 (1933).—The Faraday method of attraction and repulsion in a non-uniform magnetic field was used. The app. used was that of Poey and Forrer (C. A. 21, 2201). The magnetic susceptibilities were:  $MnSO_4$  28.99,  $Gd_2(SO_4)_3$  38.62,  $Gd_2O_3$  38.78,  $Dy_2O_3$  51.73. Deviations of exptl. values from those of the quantum theory of Weiss magnetism whole nos. are compared. **E. M. Symmes**

**Experimental contribution to the magnetic rotation of nickel.** Kurt H. v. Klitzing. *Z. Physik* 85, 240-52 (1933).—The rotation of the plane of polarization of light on reflection at the surface of magnetic Ni (Kerr effect) or passage through transparent Ni films placed in a longitudinal magnetic field (Faraday effect) was studied in its dependence on temp., on the wave length of light (infrared) and on the field strength. The rotation diminishes with increasing wave length, passes zero (at  $1.5 \mu$ ) and assumes increasingly neg. values (Kerr effect). The same is true though with reversed sign for the Faraday effect; the min. is shifted to  $1 \mu$  in this case. The rotation is largely proportional to the magnetization. **E. B.**

**Magnetic susceptibility of electrolytically prepared palladium-hydrogen alloys.** Borje Svensson. *Ann. Physik* 18, 299-304 (1933).—Pd wires 40 mm. long and 0.75 mm. in diam. were charged electrolytically with various concns. of H. The g.-at. susceptibilities are given for 15 concns. of H up to H/Pd = 0.846. For pure Pd  $\chi \times 10^6$  = 580, and  $\chi$  diminishes linearly with increasing H concn. to H/Pd = 0.66, when an abrupt change in the slope of the curve occurs at a small neg. value for  $\chi$ . ( $\chi \times 10^6$  is 45.3 for H/Pd = 0.622 and it is -8.6 for H/Pd = 0.646.) By extrapolation, for H/Pd = 1,  $\chi \times 10^6$  = -15. These results agree well with previous values given by Briggs, and the  $\chi$ -H/Pd lines have the same general character as those found by Aharoni and Simon for Pd charged in an atm. of H, although their values are somewhat less and the break in their curve occurs at H/Pd = 0.53 with no neg. values for  $\chi$ . Comparison with the behavior of the Pd-Ag alloys suggests that this behavior is due to the formation of a series of alloys of PdH with Pd. **W. W. Stiller**

**Lack of inertia of the diamagnetic Faraday effect.** W. Hanle. *Z. Physik* 85, 304-9 (1933).—The magnetorotation of Hg vapor was studied with a high-frequency magnetic field. No diminution of the Faraday effect was noted when the field frequency was increased from 50 cycles to  $10^8$ . Light near the resonance line was used. **Egon Bretscher**

**The diamagnetism of organic compounds with respect to the effect of temperature and constitution. I. The primary alcohols, nitrobenzene and *m*-cresol.** B. Cabrera and H. Fahlénbrach. *Z. Physik* 85, 568-91 (1933).—The method of C. A. 27, 4143 to det. the temp. dependence of magnetic susceptibility is applied to org. compds. The mean mol. susceptibilities are: MeOH -21.60, EtOH -33.73, PrOH -45.20, BuOH -56.32,  $C_6H_5OH$  -79.81,  $C_6H_4OH$  -102.65,  $C_6H_3OH$  -147.70 (all values times  $10^6$ ). The mol. susceptibility increases for every  $CH_2$  group by -11.48. The susceptibility changes very considerably near the m. p., but remains const. for large temp. intervals of the liquid and solid phases. The susceptibility difference above and below the m. p. increases very much with the elec. moment of the mol. The abs. susceptibilities for PhNO<sub>2</sub> and *m*-cresol are, resp., 0.5090,  $0.6090 \times 10^{-6}$ . **E. Bretscher**

**Paramagnetic Faraday effect in alums.** H. Kaufmann

*Ann. Physik* 18, 251-64 (1933).—The Faraday effect in Cr and Fe alums was measured for a field strength of 20,800 gauss. The paramagnetic contribution was detd. by comparison with isomorphous Al alum. The results are compared with the predictions of various theories. Contrary to the predictions of Rosenfeld's theory, the  $Fe^{+++}$  ion in the  $^6S$  state has a comparatively large paramagnetic component. Calculs. based on the empirical values for the intensities also fail to agree with theory. With Cr alum, comparisons are difficult because of the no. of possible transitions and the smallness of the effects. **W. W. Stiller**

**Susceptibility of paramagnetic solutions.** G. Poëx. *Compt. rend.* 197, 749-51 (1933); cf. C. A. 26, 3156.—Fahlenbrach showed that solns. of certain salts of the Fe group obey the Curie-Weiss law,  $\chi(T - \theta) = C$ , and computed the moments of the ions, with  $C$  as the Curie const. On the other hand, Gorter maintained that the ionic moment depends upon the temp. and that the product  $\chi T$  should be used as the Curie const. in computing ionic moments. He argued that the variation in moment, either with temp. or concn., would be due to the formation of complexes; the Curie-Weiss law seems to be obeyed because the variation of moment in the temp. range used ( $65^\circ$  in Fahlenbrach's work) is less than 1%. Poëx points out that arguments based on theoretical grounds can hardly be conclusive since the theory itself may be questioned. He supports G.'s position by citing addnl. exptl. evidence: (a) Chaudron showed that solns. of Co salts obey the Curie-Weiss law within 0.2% over a temp. interval of  $130^\circ$ . Auer's recent work confirms C.'s values for  $C$  and  $\theta$ . Hence G.'s arguments based on low precision and small temp. interval do not hold for these data. (b) Anhyd.  $CoSO_4$  can be prep. either with 25 or with 26 magnetons as the moment of the Co ion, and solns. of these salts preserve this moment and obey the Curie-Weiss law. Further, the const.  $C$  possesses the same significance for the solid and for the soln. since its value remains the same. With G.'s method of calcn. this identity of the moments in solid and liquid states disappears. These facts definitely show that the Curie-Weiss law holds rigorously for F.'s solns., that the magnetic moment is independent of the temp., and that it can be calcd. from the const.  $C$ . **W. W. Stiller**

**Report on paramagnetism.** W. J. de Haas and L. C. Wiersma. *Rapports et Communications, 6e Congr. Intern. Frod, Buenos Aires, Communications Kamerlingh Onnes Lab. Univ. Leiden Suppl. No. 74, 36-70 (1932)*—van Vleck's formula for the magnetic moment of NO as a function of the temp. was verified from  $292^\circ K.$  to  $113^\circ K.$  Within this range the exptl. values differ from those calcd. theoretically by only a few tenths of 1%. At  $292.10^\circ K.$ ,  $\chi \times 10^6$  = 49.07, while at  $112.77^\circ K.$  it equals 87.32. The results of a no. of studies on  $O_2$  from room temp. down to  $155^\circ K.$  and for various ds., are summarized. Gaseous  $O_2$  does not follow the same law as liquid  $O_2$ , since the susceptibility per unit mass depends upon the d. The precision of the results is not sufficient to decide definitely which law of variation with temp. is followed, but to a first approximation many of the results can be represented by  $\chi(T + 1.7) = C$ . Among the solids, tabulated results for the temp. range  $290^\circ$  to  $14^\circ K.$  are given for  $K_2SO_4$ ,  $Cr_2(SO_4)_3 \cdot 24H_2O$ ,  $CuSO_4 \cdot 5H_2O$ ,  $NiSO_4 \cdot 7H_2O$ ,  $CeF_3$ ,  $CeCl_3$ ,  $Nd_2(SO_4)_3 \cdot 8H_2O$ ,  $Pr_2(SO_4)_3 \cdot 8H_2O$ , and  $Pr_2(SO_4)_3$ . The exptl. values for the moments VI, VIII, VII, Cr<sup>III</sup>, Cr<sup>II</sup>, Mn<sup>II</sup>, Fe<sup>III</sup>, Fe<sup>II</sup>, Co<sup>II</sup>, Ni<sup>II</sup>, Cu<sup>II</sup> are compared with the corresponding values calcd. according to the theories of Hund, Laporte-Sommerfeld and Bosc-Stoner. In general, the exptl. values agree with the Rose-Sommer predictions. The cryomagnetic anomalies presented by the behavior of  $CuCl_2$ ,  $CuSO_4$  and  $FeCl_3$  are treated in some detail. In the rare earth group many of the expts. bear on the question of an odd or an even no. of electrons in the ion. **W. W. Stiller**

**A law of discontinuous distribution of ferromagnetic Curie points. III. Applications.** Robert Forrer. *J. phys. radium* [7], 4, 427-39 (1933).—The ferromagnetic

Curie points obey the law  $\Theta = F\sqrt{N}$ , where  $\Theta$  is the Curie point temp.,  $F$  is a const. equal to 301, and  $N$  is an integer which gives the no. of effective contacts per atom between the orbits of the electron lattice (cf. C. A. 27, 3309). By starting with the known Curie points and structures of a no. of bodies, the no. of contacts is computed for each, and the structure of the electron lattice of orientation is deduced. This method is applied to such problems as the transformation of hexagonal Co, the Curie points of magnetite and the ferrites, and the behavior of certain alloys, and such questions as the change in the direction of easy magnetization and the range of viscosity in hexagonal Co are considered. Analysis of magnetite reveals the presence of the strongly bound group  $\text{FeO}_4$ . The method is then extended beyond the range of ferromagnetism to include the consideration of Rochelle salt and various substances with paramagnetic Curie points. The law is generally applicable to homopolar bonds and will find many applications in the study of solid bodies.

W. W. Stiller

**Dielectric constant of  $\text{H}^2\text{H}^2\text{O}$ .** Gilbert N. Lewis, Axel R. Olson and Wm. Maroney. *J. Am. Chem. Soc.* 55, 1731 (1933).—The ratio  $D_2/D_1$ , the dielec. const. of  $\text{H}^2\text{H}^2\text{O}$  to that of  $\text{H}_2\text{O}$ , is 0.990 at  $25^\circ$  at infinite wave length. The divergence between the 2 kinds of water increases with diminishing temp.

C. J. West

**Dielectric constants. Ethanol-diethyl ether and urea-water solutions between  $0^\circ$  and  $50^\circ$ .** Jeffries Wyman, Jr. *J. Am. Chem. Soc.* 55, 4116 (1933).—The dielec. const. of urea  $\text{H}_2\text{O}$  solns. approaches 108 at a concn. of about 8 moles per l. at  $0^\circ$ . The results are applied to the studies of Lange and Robinson (C. A. 25, 636) on the heats of diln. of KCl in 5% urea solns.

P. T. Newsome

**Study of the effect of a magnetic field on the dielectric constant of argon and oxygen by a new resonance method.** H. Voss. *Z. Physik* 85, 173 (1933).—This resonance method works at the steepest part of the resonance curve instead of the usual peak. The advantage is increased sensitivity. A detector circuit contg. 2 thermocouples (connected in such a way that they offset each other if the current is the same and loosely coupled to the oscillator and the resonant circuit) and a galvanometer serves to det. the resonance and to compensate fluctuations of the oscillator. The effect of a magnetic field on the dielec. const. of A and O<sub>2</sub> was detd. No effect larger than  $\Delta\epsilon \sim 1 \times 10^{-7}$  was found.

Egon Bretschner

**Effect of methyl, ethyl and phenyl groups on the course of association of salicylic acid derivatives.** Kazimierz Kalinowski. *Roczniki Chem.* 13, 384 (1933).—Cryoscopic  $\text{C}_6\text{H}_6$  was used as the non-polar solvent. Dipole moments and the degree of assoc. (in percentage) at  $40^\circ$  follow: salol  $3.15 \times 10^{-18}$ , 71.56; Et ester  $2.88 \times 10^{-18}$ , 62.37; Me ester  $2.41 \times 10^{-18}$ , 51.7; at  $13.2^\circ$ : Me ester  $2.41 \times 10^{-18}$ , 55.86. The substances studied are dipole compds. The effect on assoc. is greatest with the Ph group; it is least with Me. C. T. Ichniowski

**Dipole moment and group rotation. I. The moments of the chloro- and nitro-benzyl chlorides and the effect of group separation.** J. M. A. & Bruyne, Rose M. Davis and Paul M. Gross. *J. Am. Chem. Soc.* 55, 3936 (1933); cf. C. A. 26, 3708, 4219.—The dielec. const.,  $d_s$ , and  $m_s$  of dil.  $\text{C}_6\text{H}_5$ ,  $\text{CCl}_4$  and  $\text{C}_6\text{H}_5$  solns. of *o*-, *m*- and *p*-chlorobenzyl chlorides were detd. at  $30^\circ$  and also those of dil.  $\text{C}_6\text{H}_5$  and  $\text{CCl}_4$  solns. of *o*- and *m*-nitrobenzyl chlorides and the dipole moments calcd. from the results. The effect on the dipole moment of  $-\text{CH}_2\text{Cl}$  was found to be 1.85 debyes when attached to a Ph group with the ring substituent *p*- or *m*- to the  $-\text{CH}_2\text{Cl}$ .

J. W. Shipley

**The estimation of electric moment in solution by the temperature coefficient method. I. Experimental method and the electric moments of some benzyl compounds.** Fred Fairbrother. *Proc. Roy. Soc. (London)* A142, 173 (1933).—The detn. of elec. moment in soln. at different temps. by measurements of dielec. const. and  $d$  in soln. is discussed. The dielec. polarizations were estd. for both the *cis* and *trans* isomers of decahydronaphthalene.

Both isomers, a mixt. of the 2 (used as a solvent in the remaining work), and *p*-xylene are non-polar. For these substances the polarization increases slightly with rise of temp. The polarizations of  $\text{PhCH}_2\text{OH}$  and  $\text{PhCH}_2\text{Cl}$  were measured from  $20^\circ$  to  $160^\circ$  while their estd. elec. moments are resp.  $\mu = 1.6 \times 10^{-18}$  e. s. u. and  $\mu = 1.72 \times 10^{-18}$  e. s. u. The polarizations of *o*-, *m*- and *p*-nitrobenzyl chlorides were measured in *p*-xylene from  $20^\circ$  to  $120^\circ$ . The effect of temp. upon the polarizations and the elec. moments is discussed and correlated with the rotation of the  $-\text{CH}_2\text{Cl}$  group about its axis. Calvin Brous

**Experimental investigations of the electrical Kerr effect in gases and vapors at higher temperatures.** H. A. Stuart and H. Volkmann. *Ann. Physik* 18, 121-40 (1933), cf. C. A. 27, 1973.—An expl. arrangement is described by which abs. measurements of the Kerr const. of vapors accurate to 3% were obtained at temps. up to  $230^\circ$ . The temp. dependence of the Kerr const. of  $\text{EtCl}$  was measured between  $18^\circ$  and  $177^\circ$ . The observations further confirm the Langevin-Born orientation theory of the effect. Kerr consts. are given for a series of org. vapors, and the polarization ellipsoids for  $\text{EtNO}_2$  and the first members of the ketones are calcd. and discussed. In contrast to the lower ketones, the Kerr const. of diisopropyl ketone is neg., and the elongated configurations are preferred in  $\text{Et}_2\text{CO}$ . Data are tabulated for 33 compds.

Allen S. Smith

**Determination of density and viscosity of gases with the aid of the Schilling-Bunsen apparatus.** W. Schiller. *Forsch. Gebiete Ingenieurw. A or B* 4, 225 (1933).

M. C. Rogers

**Thermodynamic deduction of the law of infinitely dilute gases.** Domingo Maturo. *Rev. facultad quim. ind. agr., Univ. natl.itoral* 2, 38-49 (1932).—With the definitions of an ideal gas, i. e.  $(\partial U/\partial v)_T = 0$  and  $(\partial H/\partial v)_T = 0$ , as a starting point and by assuming that in any real gas it is impossible to reach zero pressure by any finite reversible isometric process, it is shown that  $\lim P = 0$ ,  $\lim MPV = kT$ . The application of this equation to the thermodynamic temp. scale and to the detn. of mol. wts. is discussed.

J. B. Austin

**Upper pressure limit of ignition.** N. N. Semenov. *Nature* 132, 566-7 (1933).—Polenic against Hinshelwood (cf. C. A. 27, 2084). Reply. C. N. Hinshelwood. *Ibid.* 567.

Cliff M. Evans

**Density of a vapor in equilibrium with a liquid near the critical temperature.** J. S. Tapp, E. W. R. Steacie and O. Maass. *Can. J. Research* 9, 217-39 (1933), cf. C. A. 25, 4771. Expts. were made with  $\text{Me}_2\text{O}$  in the neighborhood of the crit. point to find evidence of the discontinuity of state from observations of the  $d$ . above and below the position in the tube where the meniscus disappeared. D. detns. were made on both the liquid and gaseous phases, almost simultaneously, by measuring the elongation of a quartz spiral attached to a float submerged at will in the liquid or gaseous phase. The  $d$ . above the position of the disappearance of the meniscus was found to be less than that below this position for several degrees above the temp. at which the meniscus disappeared providing there was no temp. gradient in the tube. Heating the bottom of the tube  $0.1^\circ$  warmer than the top equalized the  $d$ . within the tube while heating the bottom to  $0.2^\circ$  above that of the top reversed the  $d$ . conditions observed when the temp. of the tube was uniform. Heating the top of the tube  $0.2^\circ$  above that of the bottom accentuated the difference in  $d$ s. Vigorous stirring of the contents had no effect upon the final  $d$ . obtained. A tube of such dimensions that the meniscus neither rose nor fell while the temp. was raised to the crit. point exhibited no difference in  $d$ . between the gaseous and liquid phases at the crit. point.

J. W. Shipley

**The vapor pressures of propane and propylene.** Alfred W. Francis and Geoffrey W. Robbins. *J. Am. Chem. Soc.* 55, 4339-42 (1933).—The vapor pressure of propane was detd. over the temp. range  $27^\circ$  to  $64^\circ$  and propylene over the range  $29^\circ$  to  $46^\circ$ . The pressure was detd. by observing the vol. of air inclosed in a special glass tube

with the liquid.<sup>1</sup> The vapor pressure in atm. is  $\log P = 4.875 - (1010/T)$  for propane and  $\log P = 4.357 - (983/T)$  for propylene.

P. T. Newsome

An azeotropic mixture of secondary butyl alcohol and secondary butyl bromide.<sup>2</sup> David F. Houston. *J. Am. Chem. Soc.* 55, 4131-2 (1933).—Secondary BuOH and secondary BuBr form an azeotropic mixt.  $b_{760}$  87.2°, having  $n_D^{20}$  1.4256 and contg. 71.0 = 0.4 mols. % of the bromide.<sup>3</sup>

P. T. Newsome

Ternary azeotropic mixtures. III. The heteroazeotrope composed of ethanol, water and carbon disulfide. W. Swietoslawski and E. Wardziński. *Roczniki Chem.* 13, 380-3 (1933); cf. *C. A.* 26, 1490.—The modified ebullioscopic app. was applied to the investigation of the system  $H_2O-EtOH-CS_2$ . The method of adding successively small portions of one component to the binary mixt. of the 2 others was applied. The mixt. 92.36%  $CS_2$ , 6.55%  $EtOH$  - 1.09%  $H_2O$ ,  $b_{760}$  41.345°, was found to be the one which would cross the heteroazeotropic line of the binary mixt.  $CS_2-EtOH$  at approx. right angles. The equation best fitting the curve is  $x + 1.4y = 101.53$ ;  $x$  = percentage  $CS_2$ ,  $y$  = percentage  $EtOH$ ;  $z$  is found from  $x + y + z = 100$ . The relation between the coeffs. was found as  $dp/dx_{hetero} = dp/dx_{H_2O} = 1.05$  ( $p = 1$  atm.).

C. T. Ichniowski

Bumping prevention. John E. S. Han. *Ind. Eng. Chem., Anal. Ed.* 5, 362 (1933).—Sieve plates of Ag or Pt are used.

G. G.

Report on specific gravity of alcohol. Alfred W. Hanson. *J. Assoc. Official Agr. Chem.* 16, 535-6 (1933).—The directions for standardization of pycnometer and detn. of the sp. gravity of alc. were rewritten to conform with the new alc. tables adopted by the A. O. A. C. (0-25% by vol., at 25/25°, 20/20°, 15.6/15.6°). A. P. C.

The measurement of viscosity by oscillating columns. S. Venkataraman. *Indian J. Physics* 8, 25-42 (1933).—

The viscosities of a no. of org. liquids and  $H_2O$  were measured by photographing the damping of their oscillations in a tube. The mathematics of the problem were modified and extended.

C. E. P. Jeffreys

Viscosity of  $H^2H^2O$ . Gilbert N. Lewis and Ronald T. Macdonald. *J. Am. Chem. Soc.* 55, 4730-1 (1933). By use of 90%  $H^2H^2O$  and by calcg. values for pure  $H^2H^2O$ ,  $\eta$  at 5-35° (5° intervals) is: 19.88, 16.85, 14.51, 12.60, 11.03, 9.72, 8.64. These results do not agree with those of Selwood and Frost (*C. A.* 27, 5636).

C. J. West

The constants of the Hagenbach correction to Poiseuille's law. Max Lippke. *Z. tech. Physik* 14, 412-18 (1933).—Rik's (cf. *C. A.* 24, 1000) modification of the Hagenbach correction does not satisfy the relations for small laminar flows and has no phys. significance because the coeff. depends on the tube diam. and on the velocity of flow. Integration of the fundamental hydraulic equation leads to a rule for pressure loss that agrees with expt. Every viscometer is characterized by a pressure at which flow obeys the original Poiseuille equation.

A. F.

The electric birefringence of camphor. Marcel Schwob. *Compt. rend.* 197, 615-17 (1933).—The elec. birefringence of liquid racemic camphor and of its  $CCl_4$  and kerosene solns. was measured by the stroboscopic method (cf. *C. A.* 27, 4460, 5225). The dispersion is normal. The variation of the birefringence with temp. obeys Langevin's law. The birefringence is modified by the solvent and decreased by diln.

Janet E. Austin

The electric conductivity of inorganic material with electronic conduction. Wilfried Meyer. *Z. Physik* 85, 278-93 (1933).—Cond. measurements at various temps. lead to the following results: The cond. of satd. compds. decreases proportionally to the no. of atoms of metalloidal nature ( $WO_3$ ,  $ZnO$ ,  $CdO$ ,  $TiO_2$ ) in the crystal lattice, while the reverse is true of unsatd. compds. ( $CuI$ ,  $Cu_2O$ ,  $NiO$ ,  $CoO$ ,  $UO_2$ ); e. g., the resistance  $w$  of  $WC_3$  at room temp. was  $10^8$  cm., but treatment at high temp. in high vacuum removed large quantities of  $O_2$  and the resistance fell to 0.1 cm.  $w$  varies with temp. according to the formula  $w = a^{1/T}$ , in which  $a$  and  $b$  are const.,  $T$  is abs. temp.

Egon Bretscher

Electric conductivity of single crystals. Wilhelm Lohfeldt. *Z. Physik* 85, 717-26 (1933).—The conductivities of  $LiF$ ,  $LiCl$ ,  $NaF$ ,  $NaCl$ ,  $NaBr$ ,  $NaI$ ,  $KF$ ,  $KCl$ ,  $KBr$ ,  $KI$ ,  $RbCl$ ,  $RbBr$ ,  $AgCl$ ,  $AgBr$ ,  $TlCl$  and  $TlBr$  were detd. between -180° and the m. p. Ohm's law is generally valid, but the cond. depends on temp. in agreement with van't Hoff's equation.

Egon Bretscher

Superconductivity. F. Zwicky. *Proc. Natl. Acad. Sci.* 19, 818-22 (1933).—A discussion of the still-unresolved difficulties in explaining supercond.

Gregg M. Evans

Superconductivity and its theoretical importance. Carl Benedicks. *Arkiv Mat. Astron. Fysik* A23, 1-20 (1933); cf. *C. A.* 27, 4140.—The equil. diagrams of  $In-Pb$ ,  $Hg-Pb$ ,  $Bi-Pb$ ,  $Sn-Tl$ ,  $In-Tl$  and  $Pb-Tl$  are considered with the corresponding curves for normal cond. and supercond. It seems possible to reconcile the breaks in the supercond. curves with the corresponding breaks in the equil. curves by means of the "phoretic" or "contact" theory of elec. cond. The  $In-Pb$  curves especially indicate that supercond. appears in exactly the same manner between atoms of different elements as between atoms of the same element. Numerous observations of unexpected supercond. phenomena, e. g., supercond. of  $Au_3Si$ , are examd. and shown to fit well into the phoretic theory but not into others. The arguments for and against the phoretic theory of elec. cond. are restated and amplified.

Oden B. Sheppard

Pleochroism and the birefringence of the nitrate ion in crystals. K. S. Krishnan and A. C. Dasgupta. *Indian J. Physics* 8, 49-66 (1933).—The pleochroism and principal  $n$ s of  $KNO_3$  crystal were measured in the visible and in the near ultra-violet. The absorption band at about 3000 Å. due to  $NO_3$  ion was found to be strongly polarized, light vibrations in the plane of the ion being absorbed considerably more than those along the normal to the ionic plane. This absorption band has no effect on the principal  $n$ s of the ion.

C. E. P. Jeffreys

The optical properties of metallic and crystalline powders. A. H. Pfund. *J. Optical Soc. Am.* 23, 375-8 (1933).—Metallic "blacks" of Au, Ag, Ni, Cu, Zn, Cd, Pb, Bi, Sn, Se and Fe were prepd. by distn. in H or air, at a pressure of 3-5 mm. The films were deposited on a thin sheet of nitrocellulose which floated on Hg. The transmissions of films of Se, Te, Bi, Zn and NaCl prepd. in this manner are shown graphically for wave lengths from 0.8 to 11  $\mu$ . The transmissions and reflections are also shown for cryst. quartz with a particle diam. of 5  $\mu$  between 4.5 and 10.5  $\mu$  and for calcite with a particle diam. of 7  $\mu$  between 3.8 and 8  $\mu$ . The prepn. of filters with high and narrow transmission bands is discussed.

G. M. P.

The dependence of the lattice constant on the hydrogen concentration in the system palladium-hydrogen. Gunnar Rosenbalt. *Ann. Physik* 18, 150-4 (1933).—A more exact detn. of H concn. in the system Pd-H was made, with a detn. of the lattice const., to ascertain the accuracy of previous measurements (cf. Krüger and Gehm, *C. A.* 27, 2361). The results agree well with those of Linde and Borelius (*C. A.* 22, 1006) and indicate a miscibility gap in the system. The value of the const. for the compd.  $Pd_3H$  was found to be 9.985 Å. U.

Allen S. Smith

Effective radius of hexamine cations  $M(NH_2)_6$  in crystals of fluorite type. G. Böttcher-Naess and O. Hassel. *Z. Physik. Chem.* B22, 471-2 (1933).—Effective radii of cations were detd. by measurements on  $M(NH_2)_6X_2$ , where  $M$  = Mg, Ca, Mn, Fe, Co, Ni, Zn, Cd and  $X$  = Cl, Br, I and  $ClO_4$ .

G. M. Murphy

X-ray investigation of the crystal structure of *p*-aminoazobenzene. Mata Prasad and M. R. Kapadia. *Indian J. Physics* 8, 77-81 (1933).—Crystals of *p*-aminoazobenzene were investigated; a Shearer tube with Cu anti-cathode was used. The lengths of the axes were detd. as follows  $a = 13.69$ ,  $b = 5.60$ ,  $c = 14.18$  Å. U.; and  $\beta = 81.49^\circ$ . The  $d$  was found to be 1.174. The calcd. no. of mols. in the unit cell is nearly 4. It therefore appears that the mols. in the unit cell are asymmetric.

C. E. P. Jeffreys

The crystal structures of some compounds of the K-

PtCl<sub>4</sub> type. Gerhard Engel. *Naturwissenschaften* 21, 704(1933).—Diagrams were made by the powder method with Cu K $\alpha$  rays of substances of the Ag<sub>3</sub>BCl<sub>4</sub> type. All have cubic, face-centered lattices, the elementary cube contg. 4 mols., 4 B<sup>+</sup> atoms in position (000), 8 alkali atoms in (1/2, 1/2, 1/2) and 24 Cl atoms fit (m 00) with 0.23  $\leq m \leq 0.25$  (H 61 type). The consts.  $a$  (in A. U.) and calcd. d. are, resp.: Rb<sub>3</sub>SnCl<sub>4</sub> 10.190  $\pm$  0.004, 3.216  $\pm$  0.004; Cs<sub>3</sub>SnCl<sub>4</sub> 10.348  $\pm$  0.006, 3.554  $\pm$  0.006; Rb<sub>3</sub>TeCl<sub>4</sub> 10.221  $\pm$  0.004, 3.157  $\pm$  0.004; Cs<sub>3</sub>TeCl<sub>4</sub> 10.449  $\pm$  0.005, 3.503  $\pm$  0.004; Rb<sub>3</sub>PtCl<sub>4</sub> 9.882  $\pm$  0.003, 3.957  $\pm$  0.004; Cs<sub>3</sub>PtCl<sub>4</sub> 10.185  $\pm$  0.004, 4.205  $\pm$  0.004; Rb<sub>3</sub>PbCl<sub>4</sub> 10.198  $\pm$  0.003, 3.675  $\pm$  0.003; Cs<sub>3</sub>PbCl<sub>4</sub> 10.415  $\pm$  0.005, 4.003  $\pm$  0.006. For the Pb compds. Cl<sub>2</sub> was passed into the HCl soln. of alkali chloride with PbCl<sub>2</sub>; all other salts were made by mixt. of the aq. soln. of alkali chloride and tetrachloride. All salts were yellow ppts. (Sn white), little sol., crystals of 0.04 mm. size, optically isotropic, octahedral or cubic. B. J. C. v. d. H.

X-ray studies of fatty acids. H. B. Slagle and Emil Ott. *J. Am. Chem. Soc.* 55, 4396-4404(1933).—The (001) spacings are accurately detd. for the very pure normal fatty acids C<sub>10</sub> to C<sub>18</sub>. The linear C content-spacing relation is confirmed. A new modification of the C<sub>10</sub> and C<sub>12</sub> is reported. *Ibid.* 4404-18; cf. C. A. 24, 5019; 27, 1, slight. The existence of solid solns. of mixts. of the normal gave (acids) C<sub>10</sub> to C<sub>18</sub> is demonstrated with: binary mixts. of various concns., the components differing in chain length by 2 or 3 C atoms; equimolar mixts. with chain length differences of 4 to 8 C atoms; very complex mixts. (up to 9 components). The assumption of double mols. is untenable. Victor Hicks

Ferrites II. The alkaline, alkaline earth and lead ferrites. S. Hilpert and A. Lindner. *Z. physik. Chem.* B22, 395-405(1933), cf. C. A. 26, 5233.—The ferrites of K, Rb, Cs, Ca, Sr, Ba and Pb were prepd. and studied. X-ray investigation shows that they differ considerably from the structural type of the spinel ferrites.

G. M. Murphy  
The crystalline form of 3I<sub>2</sub>O<sub>5</sub>·H<sub>2</sub>O. J. Garrido. *Anales soc. espan. fis. quim.* 31, 616-17(1933).—Crystals of 3I<sub>2</sub>O<sub>5</sub>·H<sub>2</sub>O are orthorhombic, monoclinic,  $a:b:c = 0.901:1:0.991$ ,  $\beta = 112^\circ 53'$ . The cryst. forms are:  $c(001)$ ,  $a(100)$ ,  $b(011)$ ,  $a(121)$ ,  $u(121)$ , tabular, based on (001).

E. M. Symmes  
The crystalline form of some cobaltamines of the dinitro series. W. McNabb and H. A. Alsentzer, Jr. *Z. Krist.* 85, 297-304(1933).—1,6-Dinitrotetramminecobaltic iodide is hexagonal,  $p_0 = 0.78020$ ,  $a:c = 1:0.6757$ . 1,2-Dinitrotetramminecobaltic dichromate is monoclinic, forms 111, 111, 100,  $\bar{1}00$ ,  $\pm 110, 001, 001$ , pinacoids striated,  $p_0 = 1.5960$ ,  $q_0 = 1.6388$ ,  $a:b:c = 1.2023:1:1.7388$ ,  $\beta = 155.01^\circ$ . 1,6-Dinitrotetramminecobaltic chlorinate is tetragonal, hemihedral,  $p_0 = 1.4901$ ,  $a:c = 1:1.4901$ . 1,2-Dinitrotetramminecobaltic chromate is tetragonal, hemimorphic,  $p_0 = 1.5034$ ,  $a:c = 1:1.5034$ . 1,2-Dinitrotetramminecobaltic chromate was recrystd. from a 5% (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> soln. at 45°,  $p_0 = 1.2957$ ,  $a:c = 1:1.2957$ .

G. T. Faust  
The melting point and boiling point of potassium perhenate [and melting points of thallium and silver perhenates]. D. Vorländer and Gerhard Dalichau. *Ber.* 66B, 1534-6(1933).—KReO<sub>4</sub> m. 552-3°, b<sub>760</sub> 1370°. Th(ReO<sub>4</sub>)<sub>2</sub> changes at 120° to an isotropic form, m. 527  $\pm$  3°. AgReO<sub>4</sub> m. 430° with slight decompn., and begins to decompose actively at 455°.

Foster Dee Snell  
Adsorption of electrolytes and  $\zeta$ -potential. Adolph I. Rabinovich. *Physik. Z. Sowjetunion* 4, 304-21(1933).—Criticism of Freundlich, et al., C. A. 23, 3838. A review of the theory of O. Stern, C. A. 19, 770 with extensions by R. L. W. Elder

Nature of activated carbons. II. E. Berl and L. Reinhardt. *Z. physik. Chem.* A166, 81-96(1933); cf. C. A. 26, 1843.—Different kinds of activated C were investigated by means of x-rays. The activity appears to be due to active centers on the surface of the C in the sense of the ideas of Taylor and Smekal (C. A. 23, 5395)

1 rather than to any disturbance of the crystal lattice.

G. M. Murphy  
A note on the heat of sorption of water vapor by massive gold. Elliott Pierce Barrett. *J. Am. Chem. Soc.* 55, 4008-9(1933); cf. C. A. 27, 4473.—The integral heat of sorption,  $H$ , of water vapor by massive gold as a function of the amt.,  $W$ , adsorbed is described by the equation  $H = mW^n$ ,  $m$  and  $n$  being consts. This equation is identical in form with that of Lamb and Coolidge for the sorption of org. vapors by charcoal.

P. H. Emmet.  
Discontinuity in the adsorption of gases, vapors and liquids on solid surfaces at the critical temperature under critical pressure: system propylene-alumina. H. E. Morris and O. Maass. *Can. J. Research* 9, 240-51(1933).—Search was made by sorption measurements for discontinuity in the properties of a substance at the crit. temp. and pressure. App. and technic for studying the adsorption of gases, vapors and liquids on solid surfaces in the region of the crit. temp. and pressure are described. Results with the system propylene and Al<sub>2</sub>O<sub>3</sub> are given. Adsorption from the gas and vapor phases reveals a surface complex unstable at low pressure and high temp. The  $d$  of the adsorbed phase is greater than that of the bulk phase. There is no discontinuity in adsorption processes with a change from vapor state to gaseous state. No evidence was obtained of an increase in crit. temp. on the surface of the solid. Adsorption does not occur from the liquid state, and there is a marked discontinuity in the adsorption curve with a change from liquid state to gaseous state. This is probably due to a change in the forces of attraction between liquid mols. and the solid as compared with the attraction between gaseous or vapor mols. and the solid surface. This is further evidence for the discontinuity in the region of the crit. temp. (cf. Winkler and Maass, C. A. 27, 5226).

J. W. Shipley  
The application of glass filters to the determination of the adsorptive or catalytic activity of technical adsorbents. Franz Krczil. *Chem.-Ztg.* 57, 803-5(1933).—The superiority of fritted-glass diaphragms over other methods for filtering gas, for bubbling gas through liquids, and for supports for solids over which gases flow is pointed out. Thirteen forms of lab. app. are illustrated. G. B. T.  
Atomic hydrogen on glass and calcium fluoride. J. H. deBoer and J. J. Lehr. *Z. physik. Chem.* B22, 423-30(1933).—The adsorption of at. H was studied on glass and CaF<sub>2</sub>. The latter surface adsorbs much more H than does glass at room temp. and adsorbs it more rapidly.

G. M. M.  
Ionic exchange and sorption of gases by chabazite. E. Rabinowitsch and W. C. Wood. *Nature* 132, 640(1933); cf. C. A. 26, 3162.—The replacement of 1 Ca ion by 2 Na ions seems to close the sorption space for N but not for H. Two K ions, however, show a marked closing effect for H.

Gregg M. Evans  
The adsorption of thorium B by thallium halide crystals in the presence of various ions. J. F. King and Paul R. Pine. *J. Phys. Chem.* 37, 851-74(1933); cf. C. A. 27, 4477.—The purest TlBr and TlI that could be prepd. showed a neg. charge and adsorbed Th B ions. The adsorption of Th B by TlI decreases with increasing concn. of HNO<sub>3</sub>. The adsorption increases in the presence of excess I ions and decreases in the presence of excess TI ions. The effect of anions on the adsorption is in the order I > CNS > Br > Cl. The effects of chromate, phosphate, oxalate, Ag, Cu and Pb ions also were detd. P. T. N.

The properties of the (electrical) double layer and the exchange adsorption of ions on non-metallic surfaces. B. P. Nikol'skii. *Physik. Z. Sowjetunion* 2, 266-81(1933); cf. C. A. 19, 770, 8402.—A review. L. W. E.

The structure of the electrical double layer. L. W. Janssen. *Physik. Z. Sowjetunion* 4, 322-33(1933).—Calcns. based on Gouy's diffuse-layer theory lead to a math. expression for potential in terms of distance from the solid surface, wall charge and ion concn. Freundlich's statement of the relation between  $e$  and  $\zeta$  is criticized as inadequate. An alternative relation is suggested for the case of the glass-water boundary. L. W. Elder

Some notes on the protective filming of liquids. C. W. B. Jeppe and B. Segal. *J. Chem. Met. Mining Soc. S. Africa* 33, 397-8(1933); cf. *C. A.* 27, 3263.—Discussion.

Phenomena involved in the motion of one of the electrodes in an electrolyte, and the electrokinetic potential. M. O. Kharmadaryan and B. I. Pervushin. *Physik. Z. Sowjetunion* 4, 334-9(1933); cf. *C. A.* 24, 4464.—The current produced by the motion of one Pt electrode in a ccl contg. dil. acid satd. with  $H_2$  varies in magnitude and direction with the concn. of dissolved  $H_2$ . An electrokinetic explanation is offered, involving the concept of polar dissolved  $H_2$  mols.

Conductivity measurements of thorium and other jelly-forming systems. Satya Prakash. *J. Phys. Chem.* 37, 907-16(1933); cf. *C. A.* 26, 357.—Cond. measurements were made (at temps. between 35° and 60°) of the jelly-forming systems Th arsenate, Th phosphate, Th molybdate, ferric arsenate and Al hydroxide. Once the equil. is established the elec. cond. becomes const. and no change is noted during or after the gel formation. On aging for a no. of days all jellies increase in elec. cond. The relation between temp. and cond. was found to be linear over a wide range of temps. The temp. of zero cond. was established by extrapolation and varied from 56° for Th arsenate to -15° for Th molybdate. The temp. coeff. is about 2% of the value for 35° with Th molybdate and Al(OH)<sub>3</sub>, and about 1-1.5% for the other jellies.

Investigation of so-called colloidal iron sulfide. J. Casares. *Anales soc. españ. fis. quim.* 31, 638-44(1933).—Addn. to a soln. of Na<sub>2</sub>S of a few drops of a FeSO<sub>4</sub> soln., boiling, then pouring into a large quantity of water, gives a black liquid. If FeCl<sub>3</sub> is used, a deep green liquid is formed. This green compd. can be obtained also by mixing FeSO<sub>4</sub> soln. with an excess of Na<sub>2</sub>S soln. and treating with H<sub>2</sub>O<sub>2</sub>, Na<sub>2</sub>O<sub>2</sub>, or a current of air. The same compds. are formed on heating gently a mixt. of alkali polysulfide and FeSO<sub>4</sub>, or Fe(OH)<sub>3</sub>, and Na<sub>2</sub>S. NaCl ppts. these green solns., forming dark green compds. in which Fe and S have the relation FeS<sub>2</sub>. These solns. are probably thioferrites in a colloidal state, and are what cause the color of the S water in Yellowstone Park.

Magnetic and x-ray studies of the aging of ferrous hydroxide. Oskar Baudisch and Lars A. Welo. *Naturwissenschaften* 21, 659-60(1933).—Freshly pptd. Fe(OH)<sub>2</sub> has the ability to reduce at room temp. alkali nitrates in the presence of O<sub>2</sub>; oxidizable compds. can be oxidized at the same time: lactic acid to pyruvic acid. In the absence of O<sub>2</sub> the Fe(OH)<sub>2</sub> remains white at room temp. but loses the qualities mentioned without losing its autoxidizability. The hydroxide aged for a few days and then oxidized with air (O<sub>2</sub>) gives ferromagnetic, red Fe(OH)<sub>3</sub> (12% H<sub>2</sub>O) free from bivalent Fe and with x-ray lines of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, possibly contg. also some  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub> (ferromagnetic). Evidently the white Fe(OH)<sub>2</sub> ages under anaerobic conditions to a compd. with less H<sub>2</sub>O, the chem. water changing to adsorption water. H<sub>2</sub>O is similarly decompd. by Fe(OH)<sub>2</sub> at 200°; it is concluded that in the presence of O<sub>2</sub> hydration water is decompd. by the compd. at room temp. to give H + OH (H<sub>2</sub>O<sub>2</sub>), thereby causing the nitrate reaction, etc. Aged hydroxide no longer possesses the labile mols. of hydration water; hence it has lost catalytic activity. The paramagnetic qualities of mol. O<sub>2</sub> affect the catalytic activity (*C. A.* 18, 3307). Recent work of Parkas and Sachse (*C. A.* 27, 3874) and of Taylor and Diamond (*C. A.* 27, 3369) confirms this opinion.

Theory of parallel deposits of solute by evaporation from the walls. H. P. Chowdhury and Satyendra Ray. *Current Sci.* 2, 91-3(1933).—A math. explanation of the formation of segments of Liesegang rings on strips of filter paper that dip into solns.

The effect of hydrogen-ion concentration on the flocculation values of chromite and aluminum oxide sols. M. Hume Bedford, W. H. Keller and J. L. Gabbard. *J. Am. Chem. Soc.* 55, 3953-6(1933).—Stability of Cr<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>

and Al<sub>2</sub>O<sub>3</sub> sols was studied. The glass electrode was used for H<sup>+</sup> measurements.

Electrophoresis of calcium salts. Giuseppe Peretti. *Boll. soc. ital. biol. sper.* 8, 498-501(1933).—Sols. of CaCl<sub>2</sub>, CaCl<sub>2</sub> + MgCl<sub>2</sub>, CaCl<sub>2</sub> + MgCl<sub>2</sub> + NaHCO<sub>3</sub>, CaCl<sub>2</sub> + Na metaphosphate, CaCl<sub>2</sub> + Na citrate were subjected to cataphoresis in a Michaelis app. Conclusions: (1) Diffusion is masked only partially by elec. forces. The presence of electroneg. complexes contg. Ca is not demonstrated merely by showing that a certain amt. of Ca appears at the anode. (2) The presence of the citrate radical leads to the formation of Ca-complex anions.

The activity coefficient of thallous chloride in protein systems. Gilbert C. H. Stone and Crawford F. Failey. *J. Phys. Chem.* 37, 935-49(1933).—The effects of various proteins in different concns. on the activity coeff. of TlCl were detd. by soly. measurements. In isoelec., electrolyte-free protein solns. the change in soly. of the satg. salt was small. The neg. logarithm of the activity coeff. in these solns. is a linear function of the protein concn., whereas this is not the case in solns. of const. alkali content, in which a point of max. soly. is obtained. With solns. of varying protein contents and const. alkali contents and varying alkali and const. protein concns. the neg. log. of the activity coeff. of TlCl rises approx. linearly with increase in the square root of the ionic strength of the soln. calcd. according to certain assumptions.

The solubility of calcium iodate in water and in aqueous solutions of some electrolytes. J. B. Chloupek, V. L. Daneš and B. A. Danešova. *Collection Czechoslov. Chem. Communications* 5, 339 42(1933); cf. *C. A.* 27, 2865.—The soly. of Ca(IO<sub>3</sub>)<sub>2</sub> in pure H<sub>2</sub>O at 25° was 3.301 g. anhyd. salt per 1000 g. H<sub>2</sub>O, the solid phase being Ca(IO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O. The solubilities in 0.1 M salt solns. were: KNO<sub>3</sub>, 4.102 g.; K<sub>2</sub>SO<sub>4</sub>, 6.290 g.; MgSO<sub>4</sub>, 5.768 g.; MgCl<sub>2</sub>, 4.924 g. The solubilities at other concns. were detd.

Acetamide as a solvent. O. F. Stafford. *J. Am. Chem. Soc.* 55, 3987-8(1933).—The approx. solubilities of 400 org. compds. and 200 inorg. compds. in fused acetamide were detd. Cellulose was the only org. compd. showing no indication of soly.

Coefficient of partition between oil and water of a substance completely miscible with either solvent. Acetone. A. Lindenberg. *Compt. rend. soc. biol.* 114, 18-19(1933); cf. *C. A.* 27, 3654.—At 20° the partition coeff. of Me<sub>2</sub>CO is 0.2 for the oil layer and is independent of the concn. or the kind of animal or vegetable oil used.

Solubilities of thallous iodate and thallous chloride in the presence of amino acids. Crawford F. Failey. *J. Am. Chem. Soc.* 55, 4374-8(1933); cf. *C. A.* 27, 4726.—The solubilities of TlIO<sub>3</sub> and TlCl in the presence of amino acids were detd. The log of TlIO<sub>3</sub> soly. is approx. a linear function of amino acid concn. Ionic radii for the salts in the presence of the  $\alpha$ -amino acids were calcd. from the dielec.-const. measurements of Wyman and McMeekin (*C. A.* 27, 2359). The radii are of the right order of magnitude, but their differences indicate that the known effect of the acids on the dielec. const. of the medium is inadequate to account for the changes observed.

The molecular weights of some dissolved substances. Allan W. Pound and James R. Pound. *J. Phys. Chem.* 37, 369-72(1933).—The mol. wts. of several org. compds. and of rhombic and monoclinic S were detd. in C<sub>6</sub>H<sub>6</sub>, CHBr<sub>3</sub>, PhOH, AcOH and paraldehyde by the f.p. method. No differences in mol. size were found for polymers and allotropes in the same solvent. Assocn. to di-mols. for some org. acids in a few of the solvents used was confirmed.

The freezing points of aqueous solutions. IV. Potassium, sodium and lithium chlorides and bromides. George Scatchard and S. S. Prentiss. *J. Am. Chem. Soc.* 55, 4355-62(1933).—The f. ps. of K, Na and Li chloride

and bromide solns. were detd. after a recalibration of the app. previously used. The bromides show greater deviations from the limiting law than the corresponding chlorides, and the deviations for salts of the same anion increase in the order K, Na, Li with the exception of dil. LiCl solns. The behavior of the  $\text{NH}_4$  salt (cf. C. A. 26, 4525) is still unexplained; it is not due to systematic error.

Allen S. Smith

Freezing points and osmotic pressures of lactose solutions. E. O. Whittier. *J. Phys. Chem.* 37, 847-9 (1933).—The f. ps. of lactose solns. were detd. and the osmotic pressures calcd. therefrom. The f. ps. of lactose solns. agree with those of sucrose solns. within 1%. The osmotic pressures of the 2 sugars are additive as estd. by f.-p. detns. of a soln. contg. both.

P. T. Newsome

Determinations of the molecular weights of carbohydates. Arthur Reiser and Hans Pringsheim. *Ber.* 66B, 1296-8(1933); cf. C. A. 27, 1257.—In reply to Berner (C. A. 27, 2429), the previous statement of P. that the use of the additivity principle in cryoscopic measurements is not permissible if  $\text{EtOH}$  is present in dil. solns. is reaffirmed. Hess and Ullmann (C. A. 27, 3199) made osmometric measurements of polymeric carbohydates in dil. soln., using, among other substances,  $\alpha$ -methylglucoside (I). B. and P. tested I in boiling  $\text{H}_2\text{O}$  and found in equally dil. solns. a colloidal condition, i. e., a slight fall in the b. p. instead of a rise. Sucrose (II) gave the same unexpected result. The data given in the literature for mol.-wt. detns. for glucose, fructose, and II show normal results; here, however, the concns. were much higher, e. g., 2.4-4.3% with sucrose. At high concns. B. and P. obtained by ebullioscopy the correct values for the mol. wts. of both I and II. They are therefore of the opinion that the detn. of the mol. wt. of carbohydates rests on very weak foundations. Such measurements cannot be used as a basis for far reaching conclusions in the chemistry of the carbohydates. The detn. of the mol. wts. of diamylose (III) and tetramylose (IV) made by Ullmann (C. A. 26, 5477) cannot be correct, because under the conditions of his expts. III must change into IV.

Louise Kelley

The viscosity of aqueous solutions as a function of concentration. II. Potassium bromide and potassium chloride. Grinnell Jones and Samuel K. Talley. *J. Am. Chem. Soc.* 55, 4124-5(1933); cf. C. A. 27, 1804.—At very low concns. the viscosity of aq. solns. of KBr is greater than that of  $\text{H}_2\text{O}$  while at moderate concns. the viscosity is less than that of  $\text{H}_2\text{O}$ . KBr has a min. viscosity at 1.9 N and KCl at 0.8 N. The viscosity of solns. of KBr is given by the equation  $\eta = 1 + 0.00474 \sqrt{c} - 0.04904c + 0.01221c^2$ ; for KCl  $\eta = 1 + 0.0052 \sqrt{c} - 0.01012c + 0.00808c^2$ .

P. T. Newsome

The validity of the Einstein viscosity law for strong electrolytes. Hans Tollert. *Naturwissenschaften* 21, 603 (1933).—The Einstein viscosity law was applied to electrolyte solns.; the vol. of ions and mol. was taken proportional to the hydration no.  $H$  (Jones and Getman, *Z. physik. Chem.* 46, 385(1904); Freundlich and Schnell, C. A. 23, 1230), and the no. of particles was taken from the (cond.) degree of dissociation. For a uni-univalent salt the viscosity  $\eta_{\text{rel}} = k.c(1 + \alpha)H$ . For dil. solns. of LiBr, LiI,  $\text{Mg}(\text{NO}_3)_2$  and  $\text{CaCl}_2$  const.  $k$  is independent of concn.  $c$ , in agreement with the Einstein law; the hydrate shells are spherical. For greater concns. of these salts and for NaCl, NaI,  $\text{CaBr}_2$ ,  $\text{SrBr}_2$ ,  $\text{MgCl}_2$ ,  $\text{MgBr}_2$  and  $\text{H}_2\text{SO}_4$   $k$  is at first fairly const. and then rises rapidly. The spherical shape of the ion hydrates becomes more and more distorted; the incompletely hydrated mol. evidently polymerize because of a lack of active  $\text{H}_2\text{O}$  mol. Mutual friction of the compds. invalidates the Einstein law. This conclusion as to dynamic condition accords with the static  $H$  values from f. p. or surface tension. The polymerization equil. of  $\text{H}_2\text{O}$  itself probably also plays a role.

Refractometric investigations. XXXVI. A rotating chamber for the interferometric determination of the refractive index of solutions. A. Kruis and W. Geffekel.

*Z. physik. Chem.* A166, 10-22(1933); cf. C. A. 23, 2022.—The method previously described for obtaining the  $n$  of a soln. by means of a rotating chamber in an interferometer was applied.

G. M. Murphy

Diffusion of metals in mercury. Fritz Weischel. *Z. Physik* 85, 29-35(1933).—A method based on cond. measurements is developed to det. the diffusion of Zn and Cd in Hg.

Egon Bretscher

Diffusion of metals in solid lead. III. Diffusion in gold-lead and silver-lead alloys. W. Seith and A. Kvil. *Z. physik. Chem.* B22, 350-8(1933); cf. C. A. 27, 690.—The mechanism of the diffusion of Au and Ag in Pb was studied by measuring the diffusion of Pb into alloys contg. 0.03 and 0.08 atoms % of Au and Ag, resp.

G. M. M.

Studies in solvent action. VII. Rotatory power of ethyl tartrate in relation to the solvent, concentration, degree of association and temperature. H. Gordon Rule, Mary M. Barnett and James P. Cunningham. *J. Chem. Soc.* 1933, 1217-23; cf. C. A. 27, 3380.—The optical rotation of Et tartrate in soln. increases in the dextro sense as the polarity of the solvent rises. Minor irregularities in solvent effect are traced to the incidence of max. and min. in the rotation-concn. diagrams or to the assocn. of the ester in soln. On theoretical grounds it is deduced that (a) the rotation of the ester in a non-polar medium should increase with the concn., and (b) the temp.-rotation curves for strongly polar and non-polar solvents, resp., should converge at higher temps., with that for the homogeneous ester assuming an intermediate position and inclination. These conclusions agree with the known behavior of Et tartrate.

G. Calingaert

Difference in size of the ions of zirconium and hafnium. Alex Hoffmann. *Naturwissenschaften* 21, 678(1933).—The lattice consts. were detd. for pure  $\text{SrZrO}_3$  and  $\text{SrHfO}_3$ ,  $a = 4.089 \pm 0.003$  and  $4.069 \pm 0.003$  A. U., resp. The radius of the quadrivalent pos. Hf is 0.01 A. U. smaller than that of the corresponding Zr; this is similar to the difference between the atoms in metallic condition.

B. J. C. van der Hoeven

Mathematical study of dissociable bivalent systems in aqueous solution. Madeleine Gex. *Arch. phys. biol.* 10, 257-91(1933); cf. C. A. 22, 1719; 23, 3406. E. R. S.

The system:  $\text{AlBr}_3\text{-SbBr}_3$  in benzene. V. A. Plotnikov and I. A. Scheka. *Z. physik. Chem.* A166, 43-50(1933).—A concd. soln. of  $\text{AlBr}_3$  and  $\text{SbBr}_3$  in PhH shows a cond. of the order of  $10^{-3}$  reciprocal ohm. The sp. and mol. conductivities show max. Electrolysis with a Cu cathode and a Pt anode liberates Sb and Br, with the latter undergoing secondary reactions. With an Sb anode, Sb seps. on the Cu cathode approx. in accordance with Faraday's law. The decompn. potential for 1 g. mol.  $\text{AlBr}_3\text{SbBr}_3$  per l. of soln. is 1.20 v. Cryoscopic measurements show that large mol. are present.

G. M. Murphy

Pseudo bases and compounds with reactive groups. Conductivity changes in systems of crystal violet base and carboxylic acids. Marius Rebec and George Mandrino. *Collection Czechoslov. Chem. Communications* 5, 317-30 (1933); cf. C. A. 25, 2991.—The rate of change of the pseudo base of crystal violet to the real base as detd. by the change of cond. of  $\text{Me}_2\text{CO}$  solns. was studied. The method at present has many drawbacks, chief of which is the difficulty in getting reproducible results. In all cases 5 cc. of 0.005 N pseudo base and 5 cc. of 0.005 N acid in  $\text{Me}_2\text{CO}$  were placed in a cond. cell and measurements taken from time to time. With the fatty acids contg. an even no. of C atoms up to  $\text{C}_{11}$  the sp. cond. rose from  $10^{-4}$  to  $5$  to  $7 \times 10^{-4}$  mhos in 30 hrs.; with benzoic acid it rose to  $3 \times 10^{-4}$ ; with glutaric acid to  $3.5 \times 10^{-4}$ ; with fumaric acid to  $9 \times 10^{-4}$  in 25 hrs.; with succinic acid to  $1.1 \times 10^{-4}$ ; and with maleic, malonic and oxalic acids it rose to  $1.6 \times 10^{-4}$  in a short time.

J. E. M.

The conductivities of tetramethylammonium salts in methanol and ethyl alcohol. T. H. Mead, O. L. Hughes and Harold Hartley. *J. Chem. Soc.* 1933, 1207-14.—The conductivities of 7 Me<sub>4</sub>N salts were detd. in MeOH at 25° over the range 0.0001 N-0.0015 N. Similar measurements were made for five of these salts in EtOH.

The mobility of the  $\text{Me}_4\text{N}^+$  ion is 70.1 in MeOH and 28.3 in EtOH. The deviations of the  $\text{Me}_4\text{N}^+$  salts from the Debye-Hückel-Onsager equation are considerable in both alic., indicating appreciable ionic assocn., and in both they are greater than those of the corresponding Et<sub>4</sub>N salts.

G. Calingaert

Measurements of the high-frequency conductivity of uni-univalent electrolytes. Ernst Glowatzki. *Ann. Physik* 18, 217-32 (1933).—Relative measurements of the high-frequency cond. of HCl and NaCl solns. were made at a frequency of  $3 \times 10^8$ . The method of Zahn and Rieckhoff (cf. C. A. 24, 3154) for measurement of the cond. change at high frequencies was improved so that an accuracy of 0.05% was possible, allowance being made for deviations from theory in the magnitude of the effect to be established accurately for uni-univalent electrolytes. The theoretical dependence of the dispersion effect of Debye and Falkenhagen (C. A. 22, 2705) on the cond. was not confirmed for these compds., and an explanation is sought in a discussion of the results. Allen S. Smith

An approach to the modern theory of solutions. John P. Sampey. *J. Chem. Education* 10, 677-8 (1933).

Philip D. Adams

The dissociation constant of hypochlorous acid: glass electrode potential determinations. John W. Ingham and John Morrison. *J. Chem. Soc.* 1933, 1200-5.—From their neutralization curves of HOCl with NaOH in the presence of a glass electrode, the value  $K^1 = 3.47 \times 10^{-8}$  at 18° is derived for the dissocn. const. of HOCl.

George Calingaert

The thermodynamic ionization constants of carbonic acid. Duncan A. MacInnes and Donald Belcher. *J. Am. Chem. Soc.* 55, 2630-46 (1933).—The first dissocn. const. of  $\text{H}_2\text{CO}_3$  was detd. at 25° as  $4.54 \times 10^{-7}$  and the second as  $5.61 \times 10^{-11}$ , with methods involving galvanic cells without liquid junctions and glass electrodes.

L. P. Hall

Thermodynamic studies on potassium and sodium sulfates. F. L. Ei-ichi Shibata, Saburo Oda and Shuzo Furukawa. *J. Sci. Hiroshima Univ., Ser. A*, 3, 227-42 (1933).—See C. A. 26, 645.

L. P. H.

The "salting-out" and "salting-in" of weak acids. I. The activity coefficients of the molecules of *o*-, *m*- and *p*-chlorobenzoic acids in aqueous salt solutions. Arthur Osol and Martin Kilpatrick. *J. Am. Chem. Soc.* 55, 4430-40 (1933).—Detns. of the solubilities of *o*-, *m*- and *p*- $\text{C}_6\text{H}_4(\text{CO}_2\text{H})$  were made in aq. soln. of their Na salts and KCl, NaCl, LiCl, CsCl, KBr and  $\text{NaClO}_4$ . The mol. solubilities and activity coeffs. were calcd. The latter are the same at corresponding concns. of the same salt for mols. of  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})$  and  $\text{PhCO}_2\text{H}$ . An explanation is offered for the fact that a weak acid may either increase or decrease in soly. when dissolved in various salt solns. II. The activity coefficients of the molecules of *o*-, *m*- and *p*-hydroxybenzoic acids in aqueous salt solutions. *Ibid.* 4440-4.—The solubilities of *o*-, *m*- and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$  were detd. in solns. of KCl, NaCl, LiCl, KBr,  $\text{NaClO}_4$  and in solns. of Na benzenesulfonate, Na *p*-toluenesulfonate and Na  $\beta$ -naphthalenesulfonate. The activity coeffs. were calcd. but the "salting-out" consts. diverge from the values for  $\text{PhCO}_2\text{H}$ . In KCl soln. the consts. decrease with the transfer of OH group to the *m*- and *p*-positions.

G. M. Murphy

Exchange between atoms and ions of a metal. Otto Erbacher. *Z. physik. Chem.* A166, 23-6 (1933); cf. C. A. 27, 2366.—The effect of surface etching and polishing on the exchange of Pb and Bi atoms and ions was investigated.

G. M. Murphy

Theory of cathodic generation of hydrogen. J. Hoekstra. *Z. physik. Chem.* A166, 76-9 (1933). Reply. M. Volmer. *Ibid.* 80.

J. H. Moore

Effect of the solvent on the potential of the chloranil electrode. Bernard O. Heston and Norris F. Hall.

*J. Am. Chem. Soc.* 55, 4729-30 (1933).—The potential of the chloranil electrode may be assumed independent of the solvent only if the electrode materials remain unsolvated under the conditions of the expt.

C. J. West

Studies on oxidation-reduction potentials. II. Changes of the oxidation-reduction potentials in the hydrolysis of starch and glycogen. Yukihiko Nakamura. *J. Chem. Soc. Japan* 54, 898-903 (1933); cf. C. A. 27, 3673.—Estn. of oxidation-reduction potentials of starch by dil. alkali and acid indicated that the 1st liquefaction is oxidation and that of 2nd hydrolysis is reduction. Glycogen showed the same result but the hydrolysis was slower than that of starch. The structure of starch is discussed.

K. Kutsura

The displacement of equilibrium by variation in the mass. J. E. Verschaffelt. *Compt. rend.* 197, 683-4 (1933).—Math. A correction in the calcs. of Etienne (C. A. 27, 4468).

Gerald M. Petty

Water vapor equilibria on vanadium and its oxides. Masanori Kobayashi. *Bull. Chem. Soc. Japan* 8, 231-45 (1933).—The oxidation-reduction equil. of V was investigated by the dynamic method of Wartenberg and Aoyama (C. A. 21, 2214). Metallic V was oxidized by water vapor in  $\text{H}_2$  at several temps. The V was prepd. by the Goldschmidt process and by analysis showed 97% of the metal. The general equations of the reaction isochor  $\log K_p = -(Q/4.571T) + C$  for the 2 systems are:  $\log K_{p,1} = -(12,333/T) + 3.141$  and for  $\text{VO}/\text{V}_2\text{O}_3$ ,  $\log K_{p,2} = -(6482/T) + 1.747$ . From these follow the heats of reaction,  $\text{V} + \text{H}_2\text{O} = \text{VO} + \text{H}_2 + Q_1$  ( $-56.4$  Cal.), and  $2\text{VO} + \text{H}_2\text{O} = \text{V}_2\text{O}_3 + \text{H}_2 + Q_2$  ( $-29.6$  Cal.). By combining these equations with that for the dissocn. of water vapor, the general equations for the dissocn. of V oxides was derived, and from these the approx. values of the heats of formation of the several oxides calcd.,  $2\text{V} + \text{O}_2 = \text{V}_2\text{O}_3 + 231.6$  Cal.,  $2\text{VO} + \frac{1}{2}\text{O}_2 = \text{V}_2\text{O}_3 + 89.0$  Cal., and  $2\text{V} + \frac{3}{2}\text{O}_2 = \text{V}_2\text{O}_5 + 320.6$  Cal. By the use of the equations for heat capacities of the substances involved in each reaction, the free energies and heats of formation were calcd. at 25°:  $2\text{V} + \text{O}_2 = \text{V}_2\text{O}_3$ ;  $\Delta F_{2980} = -216,100$  cal.,  $\Delta H_{2980} = -233,476$  cal.,  $2\text{VO} + \frac{1}{2}\text{O}_2 = \text{V}_2\text{O}_3$ ;  $\Delta F_{2980} = -82,590$  cal.,  $\Delta H_{2980} = -89,336$  cal.,  $2\text{V} + \frac{3}{2}\text{O}_2 = \text{V}_2\text{O}_5$ ;  $\Delta F_{2980} = -208,797$  cal.,  $\Delta H_{2980} = -322,812$  cal.

H. E. Mesmore

The behavior of metals, particularly lead and bismuth, in atomic hydrogen, and attempts to prepare atomic hydrogen from hydrides. Thomas G. Pearson, Percy L. Robinson and Eric M. Stoddart. *Proc. Roy. Soc. (London)* A142, 275-85 (1933).—Repetition of the expts. of Paneth (cf. C. A. 23, 5159; 24, 3750) on the dissocn. of  $\text{PbEt}_4$  confirmed his isolation of free Et and his value for its av. life. The thermal dissocn. of hydrides under low pressure in a stream of  $\text{H}_2$  yielded no at. H. The formation of  $\text{BiH}_3$  was confirmed. Further work is necessary before the traces of material reported as Pb hydride are actually confirmed as such. At. H does combine with many elements of B groups in the periodic system which do not combine directly with  $\text{H}_2$ , namely, Ge, Sn, As, Sb and Te. It does not react with metallic Pb or Bi.

Calvin Brous

Effect of nuclear substituents on side-chain reactions. I. W. S. Nathan and H. B. Watson. *J. Chem. Soc.* 1933, 1248-52.—There is a quant. relation between dipole moments of  $\text{C}_6\text{H}_4\text{X}$  and the crit. increments of the side-chain reaction of  $\text{C}_6\text{H}_5$  derivs. having X as a nuclear substituent. With X in the *m*-position, for the cases considered, the expression, derived on simple kinetic theory, is applicable, save for halogen substituents; this exception is attributed to a mesomeric effect. With X in the *p*-position, the case is far more complicated but the expression seems to be applicable.

W. E. Vaughan

Oxidation of triethylphosphine. H. W. Thompson and N. S. Kelland. *J. Chem. Soc.* 1933, 1231-6.—The oxidation of triethylphosphine vapor was studied in the temp. range from 42° to 100° and found to be a chain reaction. Explosion occurs within a crit. range of pressure. Outside of this range reaction is slight; when occurring it is detd.

by surface conditions. Vessel dimensions, inert gases and temp. all exert effects to be expected qualitatively. Deactivation in the gaseous phase as well as on the walls is important.

William E. Vaughan

The reaction of hydrogen atoms with oxygen molecules and the life-time of  $\text{HO}_2$ . John R. Bates. *Z. physik. Chem.* B22, 469-70 (1933); cf. *C. A.* 27, 4469.—The life-time of  $\text{HO}_2$  is estd. to be of the order of  $10^{-9}$  sec. from the mechanism of the reaction of HI with  $\text{O}_2$ . G. M. M.

Mechanism of bimolecular reactions in solution. Addition of methyl iodide to pyridine in several solvents. H. W. Thompson and R. E. Blandon. *J. Chem. Soc.* 1933, 1237-40.—The reaction of MeI and pyridine in  $\text{CHCl}_3$ , anisole,  $\text{PhNO}_2$  and  $\text{CCl}_4$  was studied; the activation energies are, resp., 14,200, 14,300, 15,000 and 14,800 cal. The exptl. rate is some powers of 10 slower than the theoretical rate for the gas reaction. This discrepancy is not due wholly to "solvent deactivation" because the gas rate is also "slow." Extensive drying affects the rate considerably. William E. Vaughan

The kinetics of the reduction, in acid solution, of hydrogen peroxide by iodide ion. Herman A. Liebhafsky and Ali Mohammed. *J. Am. Chem. Soc.* 55, 3977-86 (1933)

Results obtained agree with earlier data. Equil. consts. at various temps. are also given from which heat of activation is calcd. A discussion of the kinetic mechanism is given which differs from that proposed by LaMer.

R. H. Lambert

Kinetics of the decomposition of the dichlorosuccinic acids. II. V. W. Robinson and David T. Lewis. *J. Chem. Soc.* 1933, 1200-2.—The decompn. of the dichlorosuccinic acids from 25° to 80° in aq. soln. and in alk. soln. was studied; from the data were detd. as the energies of activation, 23,200 cal. for the *n*-form and 23,000 cal. for the *iso*-form, the  $E/\log B$  terms are 1027 and 982, resp. The data are compared with those for the 2 dibromo acids. Added electrolyte has a negligible effect.

William E. Vaughan

Kinetics of the decomposition of trichloroacetic acid. II. Mechanism of the decomposition of the acid in aniline solution. II. W. Patwardhan and A. N. Kapur. *Z. physik. Chem.* A166, 51-8 (1933); cf. *C. A.* 26, 2640.—The decompn. of  $\text{CCl}_3\text{COOH}$  was studied at 60°, 70° and 80° in soln. of  $\text{PhNH}_2$ , and mixts. of  $\text{PhNH}_2$  with  $\text{PhH}$  and  $\text{PhMe}$ . The latter have no effect on the reaction but serve to reduce the concn. of  $\text{PhNH}_2$ . The decompn. is unimol. with respect to the acid but bimol. with respect to the solvent. Temp. coeff. and mechanism are the same with each solvent mixt. studied. Two schemes are proposed for the mechanism. G. M. M.

The kinetics of a diene synthesis. Albert Wassermann. *Ber.* 66B, 1392-4 (1933).—The velocity of the reaction of quinone with cyclopentadiene (I) to form monocyclopentadienequinone (II) may be detd. by color measurements at different times because quinone is more highly colored than II. The reaction is bimol., as is also that of I and II to form dicyclopentadienequinone. In  $\text{C}_6\text{H}_6$  at 25°,  $k$  for the 1st reaction is about 100 times  $k$  for the 2nd reaction. The dependence of the 1st reaction upon the temp. was also studied in different solvents. L. Kelley

Kinetics of the rearrangement of  $\alpha$ -methoxystyrene. F. H. MacDougall, Walter M. Lauer and Marvin A. Spielman. *J. Am. Chem. Soc.* 55, 4089-97 (1933).— $\alpha$ -Methoxystyrene rearranges to give propiophenone and at the same time these 2 substances react to form methane and 1,2-dibenzoylpropane. The kinetics of these reactions were investigated in the temp. range 222.8-260°; both were of second order. The ratio of the reaction rate consts. remains unaltered in the temp. range studied. Both reactions have an activation energy of 34,000 cal.

William E. Vaughan

The rate of addition of methyl esters to trimethylamine. Louis P. Hammett and Helmut L. Pfluger. *J. Am. Chem. Soc.* 55, 4079-89 (1933).—The rate of the alkylation of  $\text{Me}_3\text{N}$  to  $\text{Me}_4\text{N}$  ion by the Me ester of a carboxylic acid is related to the strength of the acid by an equation of the same form as that which connects the rate of a reaction in

the general acid catalysis with the strength of the acid catalyst. It is probable that the rate-detg. step in the general acid and basic catalysis of Brønsted is a transfer of H ion from acid catalyst to substrate similar to the transfer of Me in the alkylation reaction. P. H. Hammett

The determination of the velocity of hydrolysis of acid anhydrides by the aniline-water method. I. S. E. Vles. *Rec. trav. chim.* 52, 800-26 (1933).—The velocity of hydrolysis of acid anhydrides was detd. by the method of Menschutkin and Wassilief as modified by Caudri (cf. *C. A.* 24, 2860). The following unimol. consts. were calcd. at 0° and 25°, resp., for the hydrolysis of these anhydrides: acetic, 0.0267, 0.1600; propionic, 0.0170, 0.0867; butyric, 0.0097, 0.0517; succinic, 0.0210, 0.1591; glutaric, 0.0254, 0.1616. The rate of hydrolysis of methoxyacetic anhydride was too great to measure, even at 0°. The temp. coeffs. for a 10° rise in temp. were also calcd., they are larger for anhydrides of dibasic acids than for anhydrides of monobasic acids. Similar measurements in which the  $\text{H}_2\text{O}$  was replaced with a 1:1 mixt. of  $\text{Me}_2\text{CO}$  were made with benzoic, succinic and phthalic anhydrides. The unimol. consts. for the hydrolysis of these 3 anhydrides, at 25°, in aq.  $\text{Me}_2\text{CO}$ , were 0.00028, 0.0169, 0.0747, resp. The results are compared with those of prior investigators. W. B. Keighton, Jr.

Reaction velocities of 1-chloro-2,4-dinitrobenzene and 1-chloro-2,4-dinitronaphthalene with aromatic amines. II. J. van Opstall. *Rec. trav. chim.* 52, 901-11 (1933); cf. *C. A.* 17, 2705; 27, 5065.—The velocities of the reactions between aromatic amines and 1-chloro-2,4-dinitrobenzene (I) were measured. The measurements were made at 25° and at 100° in abs. EtOH. One-fiftieth mole of amine and 0.01 mole of (I) were dissolved in a total of 250 cc. of abs. EtOH for the expt. The following bimol. consts. were found at 100°:  $\text{PhNH}_2$ , 0.2860;  $p\text{-MeC}_6\text{H}_4\text{NH}_2$ , 0.7057;  $m\text{-MeC}_6\text{H}_4\text{NH}_2$ , 0.4248;  $o\text{-MeC}_6\text{H}_4\text{NH}_2$ , 0.0295;  $\text{PhNHMe}$ , 0.03293;  $o\text{-ClC}_6\text{H}_4\text{NH}_2$ , 0.0000;  $m\text{-ClC}_6\text{H}_4\text{NH}_2$ , 0.02894;  $p\text{-ClC}_6\text{H}_4\text{NH}_2$ , 0.0792;  $o\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ , 0.0000;  $m\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ , 0.00284;  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ , 0.0000;  $p\text{-MeOC}_6\text{H}_4\text{NH}_2$ , 0.6718;  $o\text{-MeOC}_6\text{H}_4\text{NH}_2$ , 0.1656;  $p\text{-AcC}_6\text{H}_4\text{NH}_2$ , 0.0035;  $p\text{-EtOC}_6\text{H}_4\text{NH}_2$ , 2.026;  $o\text{-EtOC}_6\text{H}_4\text{NH}_2$ , 0.1872; piperidine, rapid;  $\alpha$ -naphthylamine, 0.02066;  $\beta$ -naphthylamine, 0.1817;  $o$ -aminobiphenyl 0.01037;  $p$ -aminobiphenyl, 0.08619. At 25° the reaction consts. were:  $\text{PhNH}_2$ , 0.0085;  $p\text{-MeC}_6\text{H}_4\text{NH}_2$ , 0.0212;  $m\text{-MeC}_6\text{H}_4\text{NH}_2$ , 0.0109;  $p\text{-MeOC}_6\text{H}_4\text{NH}_2$ , 0.0819;  $p\text{-EtOC}_6\text{H}_4\text{NH}_2$ , 0.0857; piperidine, 1.323. These data are compared with the data of other investigators to show that (I) reacts most rapidly with alcoholates, more slowly with aliphatic amines, and most slowly with aromatic amines. The reaction products were examd and in 2 cases products were found with m. ps. higher than reported in the literature for the same compds., i. e., 2,4-dinitro-2'-methoxydiphenylamine, m. 165°, transition of yellow to red form at 145°(?); 2,4-dinitro-2'-ethoxydiphenylamine, m. 172-3°. Similar velocity measurements were made for the reaction between aromatic amines and 1-chloro-2,4-dinitronaphthalene in abs. EtOH at 25°. The bimol. consts. obtained were:  $\text{PhNH}_2$ , 1.308;  $p\text{-MeC}_6\text{H}_4\text{NH}_2$ , 4.58;  $m\text{-MeC}_6\text{H}_4\text{NH}_2$ , 2.152;  $o\text{-MeC}_6\text{H}_4\text{NH}_2$ , 0.0597;  $p\text{-ClC}_6\text{H}_4\text{NH}_2$ , 0.2154;  $p\text{-MeOC}_6\text{H}_4\text{NH}_2$ , 11.62;  $p\text{-EtOC}_6\text{H}_4\text{NH}_2$ , 18.52. In these reactions several new substances were obtained, which have not previously been reported: 2-tolyl-2',4'-dinitro- $\alpha$ -naphthylamide, m. 136° (red form), 125° (yellow form); 3-tolyl-2',4'-dinitro- $\alpha$ -naphthylamine, m. 169°; 4-methoxyphenyl 2',4'-dinitro- $\alpha$ -naphthylamine, m. 203-4°; 4-ethoxyphenyl-2',4'-dinitro- $\alpha$ -naphthylamine, m. 160°; 4-chlorophenyl-2',4'- $\alpha$ -naphthylamine, m. 209°. Further the velocity const. for the reaction between 1-chloro-2,4,6-trinitrobenzene (picryl chloride) and  $o$ -toluidine was found to be 7.028 at 25°.

W. B. Keighton, Jr.

Isopycnals of liquid helium. II. W. H. Keelson and A. P. Keelson. *Proc. Acad. Sci. Amsterdam* 36 612-15 (1933).—The investigation previously reported (cf. *C. A.* 28, 4459) was extended and data up to 35 atm are given. The app. was not satisfactory for measure

The mobility of the  $\text{Me}_4\text{N}^+$  ion is 70.1 in  $\text{MeOH}$  and 28.3 in  $\text{EtOH}$ . The deviations of the  $\text{Me}_4\text{N}^+$  salts from the Debye-Hückel-Onsager equation are considerable in both alic., indicating appreciable ionic assocn., and in both they are greater than those of the corresponding  $\text{Et}_4\text{N}^+$  salts.

G. Calingaert

Measurements of the high-frequency conductivity of uni-univalent electrolytes. Ernst Glowatzki. *Ann. Physik* 18, 217-32 (1933).—Relative measurements of the high-frequency cond. of  $\text{HCl}$  and  $\text{NaCl}$  solns. were made at a frequency of  $3 \times 10^4$ . The method of Zahn and Rieckhoff (cf. *C. A.* 24, 3154) for measurement of the cond. change at high frequencies was improved so that an accuracy of 0.05% was possible, allowance being made for deviations from theory in the magnitude of the effect to be established accurately for uni-univalent electrolytes. The theoretical dependence of the dispersion effect of Debye and Falkenhagen (*C. A.* 22, 2705) on the cond. was not confirmed for these compds., and an explanation is sought in a discussion of the results. Allen S. Smith

An approach to the modern theory of solutions John R. Sampey. *J. Chem. Education* 10, 677-8 (1933).

Philip D. Adams

The dissociation constant of hypochlorous acid: glass electrode potential determinations. John W. Ingham and John Morrison. *J. Chem. Soc.* 1933, 1200-5.—From their neutralization curves of  $\text{HOCl}$  with  $\text{NaOH}$  in the presence of a glass electrode, the value  $K^1 = 3.47 \times 10^{-8}$  at  $18^\circ$  is derived for the disson. const. of  $\text{HOCl}$ .

George Calingaert

The thermodynamic ionization constants of carbonic acid. Duncan A. MacInnes and Donald Belcher. *J. Am. Chem. Soc.* 55, 2630-40 (1933).—The first disson. const. of  $\text{H}_2\text{CO}_3$  was detd. at  $25^\circ$  as  $4.54 \times 10^{-7}$  and the second as  $5.61 \times 10^{-11}$ , with methods involving galvanic cells without liquid junctions and glass electrodes.

L. P. Hall

Thermodynamic studies on potassium and sodium sulfates. F. L. Ei-ichi Shibata, Sahujo Oda and Sluzeto Furukawa. *J. Sci. Hiroshima Univ.*, Ser. A, 3, 227-42 (1933).—See *C. A.* 26, 645.

L. P. H.

The "salting-out" and "salting-in" of weak acids. I. The activity coefficients of the molecules of *o*-, *m*- and *p*-chlorobenzoic acids in aqueous salt solutions. Arthur Osol and Martin Kilpatrick. *J. Am. Chem. Soc.* 55, 4430-40 (1933).—Detns. of the solubilities of *o*-, *m*- and *p*- $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$  were made in aq. soln. of their Na salts and  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{LiCl}$ ,  $\text{CaCl}_2$ ,  $\text{KBr}$  and  $\text{NaClO}_4$ . The mol. solubilities and activity coeffs. were calcd. The latter are the same at corresponding concns. of the same salt for mols. of  $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$  and  $\text{PhCO}_2\text{H}$ . An explanation is offered for the fact that a weak acid may either increase or decrease in soly. when dissolved in various salt solns. II. The activity coefficients of the molecules of *o*-, *m*- and *p*-hydroxybenzoic acids in aqueous salt solutions. *Ibid.* 4440-4.—The solubilities of *o*-, *m*- and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$  were detd. in solns. of  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{LiCl}$ ,  $\text{KBr}$ ,  $\text{NaClO}_4$ , and in solns. of Na benzenesulfonate, Na *p*-toluenesulfonate and Na  $\beta$ -naphthalenesulfonate. The activity coeffs. were calcd. but the "salting-out" const. diverge from the values for  $\text{PhCO}_2\text{H}$ . In  $\text{KCl}$  soln. the const. decrease with the transfer of  $\text{OH}$  group to the *m*- and *p*-positions.

G. M. Murphy

Exchange between atoms and ions of a metal. Otto Erbacher. *Z. physik. Chem.* A166, 23-6 (1933); cf. *C. A.* 27, 2366.—The effect of surface etching and polishing on the exchange of  $\text{Pb}$  and  $\text{Bi}$  atoms and ions was investigated.

Seven years of technical  $p_n$  measuring with the indicator film. Peter Wulff. *Chem. Fabrik* 1933, 441-3.—A review of applications, with bibliography (cf. *C. A.* 21, 3855).

J. H. Moore

Effect of the solvent on the potential of the chloranil electrode. Bernard O. Heston and Norris F. Hall.

*J. Am. Chem. Soc.* 55, 4729-30 (1933).—The potential of the chloranil electrode may be assumed independent of the solvent only if the electrode materials remain unsolvated under the conditions of the expt.

C. J. West

Studies on oxidation-reduction potentials. II. Changes of the oxidation-reduction potentials in the hydrolysis of starch and glycogen. Yukihiko Nakamura. *J. Chem. Soc. Japan* 54, 898-903 (1933); cf. *C. A.* 27, 3673.—Estn. of oxidation-reduction potentials of starch by dil. alkali and acid indicated that the 1st liquefaction is oxidation and that of 2nd hydrolysis is reduction. Glycogen showed the same result but the hydrolysis was slower than that of starch. The structure of starch is discussed.

K. Kitsu

The displacement of equilibrium by variation in the mass. J. E. Verschaffelt. *Compt. rend.* 197, 683-4 (1933).—Math. A correction in the calcs. of Etienne (*C. A.* 27, 4468).

Gerald M. Petty

Water vapor equilibria on vanadium and its oxides. Masami Kobayashi. *Bull. Chem. Soc. Japan* 8, 231-45 (1933). The oxidation-reduction equil. of V was investigated by the dynamic method of Wartenberg and Aoyama (*C. A.* 21, 2214). Metallic V was oxidized by water vapor in  $\text{H}_2$  at several temps. The V was prepd. by the Goldschmidt process and by analysis showed 97% of the metal. The general equations of the reaction isochor  $\log K_p = -(Q/4.571T) + C$  for the 2 systems are:  $\text{V}/\text{VO}$ ,  $\log K_{p,1} = -(12,333/T) + 3.141$  and for  $\text{VO}/\text{V}_2\text{O}_3$ ,  $\log K_{p,2} = -(6482/T) + 1.747$ . From these follow the heats of reaction,  $\text{V} + \text{H}_2\text{O} = \text{VO} + \text{H}_2 + Q_1^0$  ( $=56.4$  Cal.), and  $2\text{VO} + \text{H}_2\text{O} = \text{V}_2\text{O}_3 + \text{H}_2 + Q_2^0$  ( $=29.6$  Cal.). By combining these equations with that for the disson. of water vapor, the general equations for the disson. of V oxides was derived, and from these the approx. values of the heats of formation of the several oxides calcd.,  $2\text{V} + \text{O}_2 = \text{V}_2\text{O}_3 + 231.6$  Cal.,  $2\text{VO} + 1/2\text{O}_2 = \text{V}_2\text{O}_3 + 89.0$  Cal., and  $2\text{V} + 1/2\text{O}_2 = \text{V}_2\text{O}_3 + 320.6$  Cal. By the use of the equations for heat capacities of the substances involved in each reaction, the free energies and heats of formation were calcd. at  $25^\circ$ :  $2\text{V} + \text{O}_2 = \text{V}_2\text{O}_3$ ;  $\Delta F_{298} = -216,100$  cal.,  $\Delta H_{298} = -233,470$  cal.,  $2\text{VO} + 1/2\text{O}_2 = \text{V}_2\text{O}_3$ ;  $\Delta F_{298} = -82,696$  cal.,  $\Delta H_{298} = -89,336$  cal.,  $2\text{V} + 1/2\text{O}_2 = \text{V}_2\text{O}_3$ ;  $\Delta F_{298} = -298,797$  cal.,  $\Delta H_{298} = -322,812$  cal.

H. E. McShore

The behavior of metals, particularly lead and bismuth, in atomic hydrogen, and attempts to prepare atomic hydrogen from hydrides. Thomas G. Pearson, Percy L. Robinson and Eric M. Stoddart. *Proc. Roy. Soc. (London)* A142, 278-85 (1933).—Repetition of the expts. of Paneth (cf. *C. A.* 23, 5159; 24, 3750) on the disson. of  $\text{PbEt}_4$  confirmed his isolation of free Et and his value for its av. life. The thermal disson. of hydrides under low pressure in a stream of  $\text{H}_2$  yielded no at. H. The formation of  $\text{BiH}_3$  was confirmed. Further work is necessary before the traces of material reported as Pb hydride are actually confirmed as such. At. H does combine with many elements of B groups in the periodic system which do not combine directly with  $\text{H}_2$ , namely, Ge, Sn, As, Sb and Tc. It does not react with metallic Pb or Bi.

Calvin Brous

Effect of nuclear substituents on side-chain reactions. I. W. S. Nathan and H. B. Watson. *J. Chem. Soc.* 1933, 1248-52.—There is a quant. relation between dipole moments of  $\text{C}_6\text{H}_4\text{X}$  and the crit. increments of the side-chain reaction of  $\text{C}_6\text{H}_4$  derivs. having X as a nuclear substituent. With X in the *m*-position, for the cases considered, the expression, derived on simple kinetic theory, is applicable, save for halogen substituents; this exception is attributed to a mesomeric effect. With X in the *p*-position, the case is far more complicated but the expression seems to be applicable.

W. E. Vaughan

Oxidation of triethylphosphine. H. W. Thompson and N. S. Kelland. *J. Chem. Soc.* 1933, 1231-6.—The oxidation of triethylphosphine vapor was studied in the temp. range from  $42^\circ$  to  $100^\circ$  and found to be a chain reaction. Explosion occurs within a crit. range of pressure. Outside of this range reaction is slight; when occurring it is detd.

by surface conditions. Vessel dimensions, inert gases and temp. all exert effects to be expected qualitatively. Deactivation in the gaseous phase as well as on the walls is important.

William E. Vaughan

The reaction of hydrogen atoms with oxygen molecules and the life-time of  $\text{HO}_2$ . John R. Bates. *Z. physik. Chem.* B22, 469-70 (1933); cf. *C. A.* 27, 4469.—The life-time of  $\text{HO}_2$  is estd. to be of the order of  $10^{-9}$  sec. from the mechanism of the reaction of  $\text{HI}$  with  $\text{O}_2$ . G. M. M.

Mechanism of bimolecular reactions in solution. Addition of methyl iodide to pyridine in several solvents. H. W. Thompson and B. E. Blandon. *J. Chem. Soc.* 1933, 1237-40.—The reaction of  $\text{MeI}$  and pyridine in  $\text{CHCl}_3$ , anisole,  $\text{PhNO}_2$ , and  $\text{CCl}_4$  was studied; the activation energies are, resp., 14,200, 14,300, 15,000 and 14,800 cal. The exptl. rate is some powers of 10 slower than the theoretical rate for the gas reaction. This discrepancy is not due wholly to "solvent deactivation" because the gas rate is also "slow." Extensive drying affects the rate considerably. William E. Vaughan

The kinetics of the reduction, in acid solution, of hydrogen peroxide by iodide ion. Herman A. Liebafsky and Ali Mohammed. *J. Am. Chem. Soc.* 55, 3977-86 (1933).—Results obtained agree with earlier data. Equil. const. at various temps. are also given from which heat of activation is calcd. A discussion of the kinetic mechanism is given which differs from that proposed by LaMer.

R. H. Lambert

Kinetics of the decomposition of the dichlorosuccinic acids. H. V. W. Robinson and David T. Lewis. *J. Chem. Soc.* 1933, 1260 2.—The decompn. of the dichlorosuccinic acids from 25° to 80° in aq. soln. and in alk. soln. was studied; from the data were detd. as the energies of activation, 23,200 cal. for the *n*-form and 23,000 cal. for the *iso*-form; the  $E/\log_e B$  terms are 1027 and 982, resp. The data are compared with those for the 2-dibromo acids. Added electrolyte has a negligible effect.

William E. Vaughan

Kinetics of the decomposition of trichloroacetic acid. II. Mechanism of the decomposition of the acid in aniline solution. II. W. Patwardhan and A. N. Kappanna. *Z. physik. Chem.* A166, 51 8 (1933); cf. *C. A.* 26, 2640.—The decompn. of  $\text{CCl}_3\text{COOH}$  was studied at 60°, 70° and 80° in soln. of  $\text{PhNH}_2$ , and mixts. of  $\text{PhNH}_2$  with  $\text{PhH}$  and  $\text{PhMe}$ . The latter have no effect on the reaction but serve to reduce the concn. of  $\text{PhNH}_2$ . The decompn. is unimol. with respect to the acid but bimol. with respect to the solvent. Temp. coeff. and mechanism are the same with each solvent mixt. studied. Two schemes are proposed for the mechanism. G. M. M.

The kinetics of a diene synthesis. Albert Wassermann. *Ber.* 66B, 1392-4 (1933).—The velocity of the reaction of quinone with cyclopentadiene (I) to form monocyclopentadienequinone (II) may be detd. by color measurements at different times because quinone is more highly colored than II. The reaction is bimol., as is also that of I and II to form dicyclopentadienequinone. In  $\text{C}_6\text{H}_6$  at 25°,  $k$  for the 1st reaction is about 100 times  $k$  for the 2nd reaction. The dependence of the 1st reaction upon the temp. was also studied in different solvents. L. Kelley

Kinetics of the rearrangement of  $\alpha$ -methoxystyrene. F. H. MacDougall, Walter M. Lauer and Marvin A. Spielman. *J. Am. Chem. Soc.* 55, 4089-97 (1933).— $\alpha$ -Methoxystyrene rearranges to give propiophenone and at the same time these 2 substances react to form methane and 1,2-dibenzoylpropane. The kinetics of these reactions were investigated in the temp. range 222.8-260°; both were of second order. The ratio of the reaction rate const. remains unaltered in the temp. range studied. Both reactions have an activation energy of 34,000 cal.

William E. Vaughan

The rate of addition of methyl esters to trimethylamine. Louis P. Hammett and Helmuth L. Pfluger. *J. Am. Chem. Soc.* 55, 4079-89 (1933).—The rate of the alkylation of  $\text{Me}_3\text{N}$  to  $\text{Me}_4\text{N}^+$  ion by the Me ester of a carboxylic acid is related to the strength of the acid by an equation of the same form as that which connects the rate of a reaction in

the general acid catalysis with the strength of the acid catalyst. It is probable that the rate-detg. step in the general acid and basic catalysis of Brønsted is a transfer of  $\text{H}^+$  ion from acid catalyst to substrate similar to the transfer of  $\text{Me}$  in the alkylation reaction. P. H. Emmett

The determination of the velocity of hydrolysis of acid anhydrides by the aniline-water method. I. S. E. Vles. *Rec. trav. chim.* 52, 809-26 (1933).—The velocity of hydrolysis of acid anhydrides was detd. by the method of Menschutkin and Wassilief as modified by Caudri, (cf. *C. A.* 24, 2660). The following unimol. const. were calcd. at 0° and 25°, resp., for the hydrolysis of these anhydrides: acetic, 0.0267, 0.1600; propionic, 0.0170, 0.0867; butyric, 0.0097, 0.0517; succinic, 0.0210, 0.1591; glutaric, 0.0254, 0.1616. The rate of hydrolysis of methoxyacetic anhydride was too great to measure, even at 0°. The temp. coeffs. for a 10° rise in temp. were also calcd.; they are larger for anhydrides of dibasic acids than for anhydrides of monobasic acids. Similar measurements in which the  $\text{H}_2\text{O}$  was replaced with a 1:1 mixt. of  $\text{Me}_2\text{CO}$  were made with benzoic, succinic and phthalic anhydrides. The unimol. const. for the hydrolysis of these 3 anhydrides, at 25°, in aq.  $\text{Me}_2\text{CO}$ , were 0.00028, 0.0109, 0.0747, resp. The results are compared with those of prior investigators. W. B. Keighton, Jr.

Reaction velocities of 1-chloro-2,4-dinitrobenzene and 1-chloro-2,4-dinitronaphthalene with aromatic amines. II. J. van Opstall. *Rec. trav. chim.* 52, 901-11 (1933); cf. *C. A.* 17, 2705; 27, 5065.—The velocities of the reactions between aromatic amines and 1-chloro-2,4-dinitrobenzene (I) were measured. The measurements were made at 25° and at 100° in abs.  $\text{EtOH}$ . One-fiftieth mole of amine and 0.01 mole of (I) were dissolved in a total of 250 cc. of abs.  $\text{EtOH}$  for the expt. The following bimol. const. were found at 100°:  $\text{PhNH}_2$ , 0.2800; *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 0.7057; *m*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 0.4248; *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 0.0295;  $\text{PhNHMe}$ , 0.03293; *o*- $\text{ClC}_6\text{H}_4\text{NH}_2$ , 0.0000; *m*- $\text{ClC}_6\text{H}_4\text{NH}_2$ , 0.02804; *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$ , 0.0792; *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ , 0.0000; *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ , 0.00284; *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ , 0.0000; *p*- $\text{MeOC}_6\text{H}_4\text{NH}_2$ , 0.6718; *o*- $\text{MeOC}_6\text{H}_4\text{NH}_2$ , 0.1650; *p*- $\text{AcC}_6\text{H}_4\text{NH}_2$ , 0.0035; *p*- $\text{EtOC}_6\text{H}_4\text{NH}_2$ , 2.026; *o*- $\text{EtOC}_6\text{H}_4\text{NH}_2$ , 0.1872; piperidine, rapid;  $\alpha$ -naphthylamine, 0.02066;  $\beta$ -naphthylamine, 0.1817;  $\alpha$ -aminobiphenyl, 0.01037; *p*-aminobiphenyl, 0.08619. At 25° the reaction const. were:  $\text{PhNH}_2$ , 0.0085; *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 0.0212; *m*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 0.0109; *p*- $\text{MeOC}_6\text{H}_4\text{NH}_2$ , 0.0819; *p*- $\text{EtOC}_6\text{H}_4\text{NH}_2$ , 0.0857; piperidine, 1.323. These data are compared with the data of other investigators to show that (I) reacts most rapidly with alcoholates, more slowly with aliphatic amines, and most slowly with aromatic amines. The reaction products were examd and in 2 cases products were found with m. p. higher than reported in the literature for the same compds., i. e., 2,4-dinitro-2'-methoxydiphenylamine, m. 165°, transition of yellow to red form at 145° (?); 2,4-dinitro-2'-ethoxydiphenylamine, m. 172-3°. Similar velocity measurements were made for the reaction between aromatic amines and 1-chloro-2,4-dinitronaphthalene in abs.  $\text{EtOH}$  at 25°. The bimol. const. obtained were:  $\text{PhNH}_2$ , 1.308; *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 4.58; *m*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 2.152; *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , 0.0597; *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$ , 0.2154; *p*- $\text{MeOC}_6\text{H}_4\text{NH}_2$ , 11.62; *p*- $\text{EtOC}_6\text{H}_4\text{NH}_2$ , 18.52. In these reactions several new substances were obtained, which have not previously been reported: 2-tolyl-2',4'-dinitro- $\alpha$ -naphthylamine, m. 136° (red form), 125° (yellow form); 3-tolyl-2',4'-dinitro- $\alpha$ -naphthylamine, m. 169°; 4-methoxyphenyl-2',4'-dinitro- $\alpha$ -naphthylamine, m. 203 4°; 4-ethoxyphenyl-2',4'-dinitro- $\alpha$ -naphthylamine, m. 160°; 4-chlorophenyl-2',4'- $\alpha$ -naphthylamine, m. 209°. Further the velocity const. for the reaction between 1-chloro-2,4,6-trinitrobenzene (picryl chloride) and *o*-toluidine was found to be 7.028 at 25°. W. B. Keighton, Jr.

Isopycnals of liquid helium. II. W. H. Keesom and A. P. Keesom. *Proc. Acad. Sci. Amsterdam* 36, 612-15 (1933).—The investigation previously reported (cf. *C. A.* 27, 4459) was extended and data up to 35 atm. are given. The app. was not satisfactory for measure-

ments on the solid. At 1.18°K. solid He has  $d > 0.1818$  g./cc. The  $\lambda$  point on the solidification curve is at  $T = 1.754^\circ\text{K}$ .  $p = 29.9$  atm. E. R. Schierz

The transformation of solid ammonium chloride at about  $-30^\circ$ . A. Smits and C. H. MacGillavry. *Z. physik. Chem.* A166, 91-112 (1933).—A dilatometric investigation was made of the transformation of  $\text{NH}_4\text{Cl}$  between  $-10^\circ$  and  $-30^\circ$ . Certain hysteresis effects were noted and are discussed. G. M. Murphy

Thermal analysis of the system hydrogen chloride-boron trichloride. W. Graff. *Compt. rend.* 197, 754-5 (1933).—Data are given for the system  $\text{HCl}-\text{BCl}_3$  in the range  $-110^\circ$  to  $-135^\circ$ , and 0 to 100%  $\text{HCl}$ .

F. D. Rossini

Extension of Braun's law to the equilibrium of binary phases. Domingo Maturro. *Rev. facultad quim. ind. agr. Univ. nac. litoral.* 2, 50 4 (1932).—Braun's law (cf. C. A. 14, 2284) is generalized to the form  $(\lambda_m^{\alpha\beta}/T)(\partial x_2^\beta/\partial p) + \Delta_m^{\alpha\beta}(\partial x_2^\beta/\partial T) = 0$ , where  $\lambda_m^{\alpha\beta}$  and  $\Delta_m^{\alpha\beta}$  are, resp., the ideal heat effect and ideal vol. change accompanying the passage of a mol. of a mixt. of 2 components from phase  $\alpha$  to phase  $\beta$  at const. temp., pressure and compn.;  $x_2^\beta$  is the mol. fraction of component 2 in phase  $\beta$ . J. B. A.

Thermal equilibrium of combinations of acetanilide with certain organic compounds. Konstanty Hrynakowski and Franciszek Adamanis. *Roczniki Chem.* 13, 448 53 (1933).—Temp.-compn. curves are given for these binary systems. The following figures are, resp., the mol. percentage of the 1st ingredient and the eutectic pt.: acetanilide antipyrine, 51.3,  $58.5^\circ$ ;  $-\text{BzOH}$ , 57.6,  $76^\circ$ ;  $-\text{quinine}$ , 84.9,  $105^\circ$ ;  $-\text{diphenylamine}$ , 12.4,  $47^\circ$ ;  $-\text{phenacetin}$ , 79.1,  $80^\circ$ ;  $-\text{hydroquinone}$ , 60.2,  $77.5^\circ$ ;  $-\text{menthol}$ , 14.8,  $35^\circ$ ;  $-\text{urea}$ , 80.3,  $102^\circ$ ;  $-\alpha\text{-naphthylamine}$ , 18.4,  $38^\circ$ ;  $-\text{salipyrine}$ , 57.4,  $64^\circ$ ;  $-\text{salol}$ , 6.2,  $40^\circ$ ;  $-\text{urethan}$ , 14.2,  $40^\circ$ . Thermal analysis showed that all belong to one class. The members of the systems do not mix in the solid state but do so in all proportions in the melted state forming eutectic mixts. C. T. I.

Thermal analysis of binary mixtures containing organic nitrates. Tadeusz Urbanski. *Roczniki Chem.* 13, 399-434 (1933).—A 2.5-g. sample, in a 12-mm. tube placed in a 43-mm. tube which in turn is placed in a 35-mm. tube contg. glycerol, is heated to  $5-10^\circ$  above its m. p. During the cooling, the melt and glycerol are stirred vigorously. Temp.-compn. curves are given. The following figures are, resp., the percentage of the 1st ingredient and the eutectic pt. Mannitol nitrate- $p$ -nitrotoluene, 12.5,  $49.2^\circ$ ;  $p$ -nitroanisole 8,  $50.8^\circ$ ;  $p$ -nitrophenetole, 5,  $56.8^\circ$ ;  $o$ -chloronitrobenzene, 15.5,  $29.7^\circ$ ;  $o$ -nitronaphthalene, 14,  $52.5^\circ$ ;  $m$ -dinitrobenzene, 52.5,  $65.5^\circ$ ;  $1,3,5$ -dinitroanisole, 55,  $77.6^\circ$ ;  $1,2,4$ -chlorodinitrobenzene, 25,  $44.5^\circ$ ;  $sym$ -trinitrobenzene, 55,  $78.7^\circ$ ;  $o$ -trinitrotoluene, 42.5,  $62.8^\circ$ ;  $n$ -naphthalene, 20,  $77.3^\circ$ ;  $dimethyldiphenylurea$ , 57,  $77.4^\circ$ ;  $diethyldiphenylurea$ , 53-4, approx.  $52.1^\circ$ . Nitroerythritol- $p$ -nitrotoluene, 47,  $32.4^\circ$ ;  $m$ -dinitrobenzene, 70,  $42.4^\circ$ . Pentaerythritol nitrate- $p$ -nitrotoluene, 10,  $50.2^\circ$ ;  $p$ -nitroanisole, 5,  $50.8^\circ$ ;  $o$ -nitronaphthalene, 4,  $55.1^\circ$ ;  $m$ -dinitrobenzene, 20,  $82.4^\circ$ ;  $1,3,5$ -dinitroanisole, 20,  $94.7^\circ$ ;  $1,2,4$ -chlorodinitrobenzene, 3,  $49^\circ$ ;  $sym$ -trinitrobenzene, approx. 30,  $101.1^\circ$ ;  $o$ -trinitrotoluene, approx. 13,  $76.4^\circ$ ;  $n$ -naphthalene, approx. 7,  $79.1^\circ$ ;  $dimethyldiphenylurea$ , 32.5,  $102.7^\circ$ ;  $diethyldiphenylurea$ , approx. 12,  $68^\circ$ ; mannitol nitrate-erythritol nitrate 18.5,  $57.6^\circ$ ; pentaerythritol nitrate-mannitol nitrate, 20,  $101.3^\circ$ ; pentaerythritol nitrate-erythritol nitrate, approx. 5,  $59.5^\circ$ . Mannitol nitrate was the only compd. giving rise to mol. addn. compds. Probable compns. (dtd. by extrapolation) are, in mols. per mol. of mannitol nitrate,  $p$ -nitrotoluene 2,  $p$ -nitroanisole 2,  $p$ -nitrophenetole 2,  $o$ -nitronaphthalene. 1. Bibliography. C. T. I.

Systems (a) ammonium  $d$ -tartrate-lithium  $d$ -tartrate-water and (b) ammonium lithium  $d$ -tartrate-ammonium lithium  $l$ -tartrate-water. Alan N. Campbell and Louis Slotin. *J. Am. Chem. Soc.* 55, 3961-70 (1933).—Soly. detns. were made at  $0^\circ$ ,  $30^\circ$  and  $60^\circ$  in the 2 ternary

systems  $\text{NH}_4 d\text{-tartrate-Li } d\text{-tartrate-water}$  and  $\text{NH}_4 \text{Li } d\text{-tartrate-NH}_4 \text{Li } l\text{-tartrate-water}$  to det. the effect on the transition temp. of the substitution of Li for Na in Na  $\text{NH}_4$  racemate. Filtration was accomplished through a sintered glass filter immersed in the thermostat. Li was detd. by ignition and conversion of the carbonate to sulfate while the  $\text{NH}_4$  was detd. by distn. A double salt,  $(\text{NH}_4)_2\text{Li}_2(\text{C}_4\text{H}_4\text{O}_6)_2$ , was formed at all 3 temps. The stability of this salt increased with the temp. In system (b) a true racemate was found at all 3 temps. having the formula  $(\text{NH}_4)_2\text{Li}_2(\text{C}_4\text{H}_4\text{O}_6)_2 \cdot \text{H}_2\text{O}$ . The transition temp. for  $\text{Li}_2\text{C}_4\text{H}_4\text{O}_6 \cdot 2\text{H}_2\text{O} \rightarrow \text{Li}_2\text{C}_4\text{H}_4\text{O}_6 + 2\text{H}_2\text{O}$  was detd. as  $21.52^\circ$  by the dilatometric method and as  $21.81^\circ$  by the soly. method. J. W. Shipley

The ternary system biphenyl-diphenylamine-benzophenone. H. Howard Lee and J. C. Warner. *J. Am. Chem. Soc.* 55, 4474-7 (1933); cf. C. A. 27, 889.—The 1. p.-compn. diagram for the ternary system biphenyl-diphenylamine-benzophenone was detd. Two stable eutectics were found: (1) at  $18.8^\circ$  with the compn. 30.5 mols. % diphenylamine and 49.0 mols. % diphenylamine and (2) at  $16.5^\circ$  with the compn. 30 mols. % biphenyl and 52 mols. % benzophenone. Two metastable eutectics were found at the lower temps.  $15^\circ$  and  $13.1^\circ$ , resp., with slightly differing compns. H. S. van Klooster

The system  $\text{CaO-FeO-SiO}_2$ . N. L. Bowen, J. F. Schairer and E. Posnjak. *Am. J. Sci.* 26, 193-284 (1933); cf. C. A. 27, 2867.—There are 3 ternary compds.  $\text{CaFeSi}_2\text{O}_6$  (hedenbergite), stable only below  $905^\circ$ ,  $2\text{-CaO.FeO.2SiO}_2$  (Fe akermanite), stable below  $775^\circ$  and  $\text{CaFeSiO}_4$ . Only the last is stable at temps. where liquid is formed in any of the mixts. There are 30 invariant points. Seven of these are ternary but none is a eutectic, the min temp. of existence of liquid in the system ( $1093^\circ$ ) being a point at which only 2 solid phases, both solid solns., are in equil. with the liquid. The outstanding feature of the system is the occurrence of solid-soln. series, the most important of which are the 2 metasilicate series and an orthosilicate series. The 1 metasilicate series extends from pure wollastonite ( $\text{CaSiO}_3$ ) to 76%  $\text{FeSiO}_3$ ; the other from hedenbergite ( $\text{CaFeSi}_2\text{O}_6$ ) to 80%  $\text{FeSiO}_3$ . Metasilicates with a higher content of  $\text{FeSiO}_3$  do not form, orthosilicate and tridymite appearing together as excess phases in such compns. The hedenbergite solid solns. are stable only at low temps. and are transformed at  $940-980^\circ$  to wollastonite solid solns. The principal orthosilicate solid solns. are Ca-Fe olivines, extending from fayalite ( $\text{Fe}_2\text{SiO}_4$ ) through  $\text{CaFeSiO}_4$  to 59%  $\text{Ca}_2\text{SiO}_4$ . Wollastonite solid solns. and Ca-Fe olivines occur together in equil. with some liquids of the system. The optical properties of the cryst. phases were measured and the variation of optical properties with compn. in the solid soln. series are shown. The x-ray diffraction patterns of members of the solid soln. series are reproduced. The bearing of the results upon the occurrence and compn. of natural minerals is discussed. Alden H. Emery

The homogeneous catalysis of gaseous reactions. The effect of iodine on the decomposition of acids, esters, ketones and halides. S. Baird and C. N. Hinshelwood. *J. Chem. Soc.* 1933, 1147-55.— $\text{I}_2$  has a very pronounced catalytic effect on the homogeneous decompn. of  $\text{HCOOMe}$  and  $\text{AcOMe}$  in the gaseous state. The catalyzed reactions are analogous to those of ethers and aldehydes (cf. C. A. 24, 5584). The decompn. of  $\text{HCOOH}$  and  $\text{AcOH}$  is not catalyzed by  $\text{I}_2$ . The catalyzed decompn. of  $\text{HCOOMe}$  proceeds mostly to  $\text{MeOH}$  and  $\text{CO}$ , the  $\text{MeOH}$  then decomp. principally to  $\text{CH}_4$ ,  $\text{H}_2\text{O}$  and  $\text{CO}$ . Neither  $\text{Ht}$  halide nor ketone decompn. is appreciably catalyzed by  $\text{I}_2$ . P. H. Emmett

The homogeneous catalysis of gaseous reactions. The effect of iodine on the decomposition of simple aliphatic amines and of hexane. S. Baird and C. N. Hinshelwood. *J. Chem. Soc.* 1933, 1155-60; cf. preceding abstr.—The structural analogy between  $\text{C-O-C}$  and  $\text{C-NH-C}$  is reflected in a certain similarity between the catalyzed decompns. of the amines and the ethers. The amine reaction in the presence of  $\text{I}_2$  as a catalyst is explained

qualitatively by the general equation  $RCH_2NHR' = R'H + RCH:NH = R'H + RH + HCN$ . The intermediate aldimines enter into complex decomposition and condensation reactions that destroy any simple quantitative relations. The H of the NH group plays no part in the amine decomposition, since the decompositions of  $(C_2H_5)_3N$  and  $(C_2H_5)_2NH$  are both catalyzed and to about the same extent. The catalyzed decomposition of  $(CH_3)_3N$  and  $(CH_3)_2NH$  occurs about  $1/10$  as rapidly as that of the ethylamines. The effect of  $I_2$  on the decomposition of  $(C_2H_5)_3NH$  and of hexane is small. P. H. Emmett

Polybasic acids as catalysts for the reduction of ammoniacal silver solutions by phosphorous acid. Bruno Blaser. *Z. physik. Chem.* A166, 64-75(1933).— $HNO_3$  soln. of  $H_3PO_4$  shows little reduction of ammoniacal soln. of  $AgNO_3$ . Addn. of  $HPO_4$ ,  $H_2PO_4$ ,  $H_2P_2O_7$  as well as  $H_2AsO_4$ , citric and aconitic acids shows marked catalytic effect on the reduction. Other acids show little effect. G. M. M.

The role of ozone as catalyst of oxidation. VI. The action of diluents of the ozone, of light and of catalysts of autoxidation. E. Briner and H. Biedermann. *Helv. Chim. Acta* 16, 1119-24(1933); cf. *C. A.* 27, 3389.—The oxidation of  $BzH$  by ozonized  $O$  was studied when the  $O_3$  was dild. with  $O_2$ ,  $N_2$  and  $CO_2$  as well as when it acted in the presence of a little  $O_2$  at 20 mm. pressure. The inert gas present aids the reaction to some extent, because the oxidation was markedly less in the low-pressure expts. Ultra-violet light does not seem to affect the oxidation with  $O_3$  although the total amt. of oxidation is increased because of autoxidation. The same is true of Cu and Co salts, which catalyze autoxidation but retard the  $O_3$  reaction almost as much as mannitol. The oxidation with  $O_3$  seems to be entirely independent of autoxidation and unaffected by promoters thereof except insofar as availability of  $BzH$  may be diminished by a strong competing reaction. VII. The ozonization of dissolved hydriodic acid. *Ibid.* 1125-30; cf. Treadwell and Anneler, *Z. anorg. Chem.* 48, 86(1906); Riesenfeld and Bencker, *C. A.* 11, 563.—No conclusive evidence could be obtained that  $O_3$  catalyzed the oxidation of HI. No yields of oxidation products above 83% were obtained, and dild. of  $O_3$  by inert gases did not reduce its activity to a marked extent. It seems probable that undissolved  $O_3$  is acted upon. The reaction is 30 times more rapid in  $HOAc$  than in aq. soln. R. Baltzly

The physical state of solid catalysts. Etienne Audibert and Andre Raineau. *Compt. rend.* 197, 596-8(1933).—Catalytically active Cu has a d. of about 7.6 instead of the normal value of 8.9 for massive material. Sintering by heating to about 700° raised the d. to the normal value. P. H. Emmett

Specific catalytic surfaces. E. K. Rideal. *Soc. Chem. Ind., Chem. Eng. Group, Proc.* 13, 45-9(1931).—Exptl. methods for detg. the sp. surface of a catalyst and for studying catalytic activity are discussed. P. H. E.

The specific activity of catalysts. E. B. Maxted. *Soc. Chem. Ind., Chem. Eng. Group, Proc.* 13, 43-5(1931).—The heat of adsorption of one of the reactants on a catalyst may supply the energy of activation required for the reaction being catalyzed. P. H. Emmett

The reduction by hydrogen and the thermal decomposition of nitrides made by the reaction of ammonia with various promoted and unpromoted iron synthetic-ammonia catalysts. P. H. Emmett and Katharine S. Love. *J. Am. Chem. Soc.* 55, 4043-50(1933).— $Fe_3N$  prepd. from active catalysts decomposes more rapidly than that prepd. from rather inactive catalysts. The energy of activation of the decomposition is about 50,000 cal. The rates and nature of the reduction and decomposition of the nitrides from the various Fe catalysts are given. P. H. Emmett

The present status of the theory of ammonia catalysts. W. Brankenburger. *Z. Elektrochem.* 39, 818-20(1933); cf. *C. A.* 27, 3561.—A reply to Kröger (*C. A.* 27, 5485) and a correction for the heat of formation of  $U_3N_4$  which is between 15 and 25 Cal./g.-atom N instead of 68.5 Cal. as previously stated. H. H. Rowley

The heat conductivity of wet masses of diatomaceous earth in relation to the specific weight and the amount of water added. E. Raisch. *Gesundh.-Ing.* 56, 509-11(1933).—Curves show that the insulating properties of wet mortar-like masses of diatomaceous earth increase with decrease in sp. wt. and also with increase in the amt. of water necessary to convert the powder into a mortar-like mass. Neither relation is linear. M. G. Moore

Low-temperature specific heats. I. An improved calorimeter for use from 14° to 300°K. The heat capacity and entropy of naphthalene. J. C. Southard and P. G. Brickwedde. *J. Am. Chem. Soc.* 55, 4378-84(1933).—An improved adiabatic "vacuum" calorimeter for solid and liquid substances is described, which can be used for studying slow transitions as well as measuring heat capacities with a precision of about 0.1%. From measurement of its heat capacity from 14° to 300°K., the entropy of naphthalene at 25° was calcd. to be 39.89 ± 0.12 cal mol.<sup>-1</sup> deg.<sup>-1</sup>. II. The calibration of the thermometer and the resistance of platinum, platinum-10% rhodium and constantan between -259° and -190°. J. C. Southard and R. T. Milner. *Ibid.* 4384-91.—A const.-vol. gas thermometer was used to measure the resistance of Pt, Pt-10% Rh, and of constantan, in the range -259° to -190°, with an accuracy corresponding to ±0.02°; a reference table of  $R/R_0$  for Pt from 14° to 109°K., and for constantan from 14° to 26°K., gives values for each degree F. D. Rossini

The heat capacities of gaseous mono- and dimethyl amine. W. A. Felsing and P. W. Jessen. *J. Am. Chem. Soc.* 55, 4418-22(1933).—A closed-system, continuous-flow calorimeter was used to measure  $C_p$ . By the Kund method, the following values of  $C_p/C_v$  were found for 25°:  $CH_3NH_2$ , 1.202;  $(CH_3)_2NH$ , 1.149;  $(CH_3)_3N$  1.184;  $C_2H_5NH_2$ , 1.135. F. D. Rossini

The heats of dilution of electrolytes. G. Chapas. *Rev. gén. sci.* 44, 535-44(1933).—A review. F. D. R.

The partial and integral heats of dilution of cadmium sulfate solutions from electromotive force measurements. Victor K. La Mer and W. George Parks. *J. Am. Chem. Soc.* 55, 4343-55(1933).—The cell reaction  $Cd(satd. Hg) + PbSO_4(s) = CdSO_4(m) + Pb(satd. Hg)$  was re-investigated (cf. *C. A.* 25, 4767), and the conclusion that the Debye-Huckel parameter "a" is 3.60 Å. U. for concns of  $CdSO_4$  of 0.0005 through 0.01 M and independent of temp. from 0° to 30° was definitely confirmed. Activity coeffs. of  $CdSO_4$  and thermodynamic quantities for the reaction are given. The concn. dependence of the relative partial molal and integral heat contents of  $CdSO_4$ , which were computed, is of the form demanded by the Gronwall-La Mer and Sandved theory. The partial molal heat capacity of  $CdSO_4$  is estd. to be approx. -200 cal./deg. mol. at 15°. Allen S. Smith

Calorimetric investigations. XXI. Heats of combustion of methyl-, ethyl- and phenyl-substituted succinic acids and of their anhydrides....(a) experimental data P. E. Verkade and H. Hartmann. *Rec. trav. chim.* 52, 945-68(1933).—The following are the isothermal heats of combustion at 19.5° at const. vol., per g. weighed in air with brass weights and expressed in 15° calories: succinic anhydride 3609.2, methylsuccinic acid 3903.3, methylsuccinic anhydride (solid) 4629.0, (liquid) 4647.3, *asym* dimethylsuccinic acid 4591.0, *asym*-dimethylsuccinic anhydride, 5330.7, *cis*-*sym*-dimethylsuccinic acid 4607.7, *trans*-*sym*-dimethylsuccinic acid 4597.5, *l-trans*-*sym*-dimethylsuccinic acid 4599.6, *cis*-*sym*-dimethylsuccinic anhydride 5318.5, *trans*-*sym*-dimethylsuccinic acid 5304.1, trimethylsuccinic acid 5183.0, trimethylsuccinic anhydride 5844.2, tetramethylsuccinic acid 5681.4, tetramethylsuccinic anhydride 6356.9, ethylsuccinic acid 4588.7, ethylsuccinic anhydride (liq.) 5347.5, *asym*-diethylsuccinic acid 5653.7, *asym*-diethylsuccinic anhydride (liq.) 6393.7, *cis*-*sym*-diethylsuccinic acid 5672.1, *trans*-*sym*-diethylsuccinic acid 5662.4, *cis*-*sym*-diethylsuccinic anhydride (liq.) 6386.7, *trans*-*sym*-diethylsuccinic anhydride (liq.) 6376.5, triethylsuccinic acid 6434.9, tri-

ments on the solid. At 1.18°K. solid He has  $d > 0.1818$  g./cc. The  $\lambda$  point on the solidification curve is at  $T = 1.754^\circ\text{K}$ .  $p = 29.9$  atm. E. R. Schierz

The transformation of solid ammonium chloride at about  $-30^\circ$ . A. Smits and C. H. MacGillavry. *Z. physik. Chem.* A166, 97-112 (1933).—A dilatometric investigation was made of the transformation of  $\text{NH}_4\text{Cl}$  between  $-10^\circ$  and  $-30^\circ$ . Certain hysteresis effects were noted and are discussed. G. M. Murphy

Thermal analysis of the system hydrogen chloride-boron trichloride. W. Graff. *Compt. rend.* 197, 754-5 (1933).—Data are given for the system  $\text{HCl}-\text{BCl}_3$  in the range  $-110^\circ$  to  $-135^\circ$ , and 0 to 100%  $\text{HCl}$ .

F. D. Rossini

Extension of Braun's law to the equilibrium of binary phases. Domingo Maturo. *Rev. facultad quim. ind. agr. Univ. nac. litoral.* 2, 50-4 (1932).—Braun's law (cf. C. A. 14, 2284) is generalized to the form  $(\lambda_m^{\alpha\beta}/T)(\partial x_2^\beta/\partial p) + \Delta_m^{\alpha\beta}(\partial x_2^\beta/\partial T) = 0$ , where  $\lambda_m^{\alpha\beta}$  and  $\Delta_m^{\alpha\beta}$  are, resp., the ideal heat effect and ideal vol. change accompanying the passage of a mol. of a mixt. of 2 components from phase  $\alpha$  to phase  $\beta$  at const. temp., pressure and compn.;  $x_2^\beta$  is the mol. fraction of component 2 in phase  $\beta$ . J. B. A.

Thermal equilibrium of combinations of acetanilide with certain organic compounds. Konstanty Hrynakowski and Franciszek Adamanis. *Roczniki Chem.* 13, 448-53 (1933).—Temp.-compn. curves are given for these binary systems. The following figures are, resp., the mol. percentage of the 1st ingredient and the eutectic pt.: acetanilide-antipyrine, 51.3,  $58.5^\circ$ ; - $\text{RzOH}$ , 57.6,  $76^\circ$ ; -quinine, 84.9,  $105^\circ$ ; -diphenylamine, 12.4,  $47^\circ$ ; -phenacetin, 79.1,  $80^\circ$ ; -hydroquinone, 60.2,  $77.5^\circ$ ; -menthol, 14.8,  $35^\circ$ ; -urea, 80.3,  $102^\circ$ ; - $\alpha$ -naphthylamine, 18.4,  $38^\circ$ ; -salipyrine, 57.4,  $64^\circ$ ; -salol, 6.2,  $40^\circ$ ; -urethan, 14.2,  $40^\circ$ . Thermal analysis showed that all belong to one class. The members of the systems do not mix in the solid state but do so in all proportions in the melted state forming eutectic mixts. C. T. I.

Thermal analysis of binary mixtures containing organic nitrates. Tadeusz Urbanski. *Roczniki Chem.* 13, 399-434 (1933).—A 2.5-g. sample, in a 12-mm. tube placed in a 16-mm. tube which in turn is placed in a 35-mm. tube contg. glycerol, is heated to  $5-10^\circ$  above its m. p. During the cooling, the melt and glycerol are stirred vigorously. Temp.-compn. curves are given. The following figures are, resp., the percentage of the 1st ingredient and the eutectic pt. Mannitol nitrate- $p$ -nitrotoluene, 12.5,  $49.2^\circ$ ; - $p$ -nitroanisole 8,  $50.8^\circ$ ; - $p$ -nitrophenetole, 5,  $56.8^\circ$ ; - $\alpha$ -chloronitrobenzene, 15.5,  $29.7^\circ$ ; - $\alpha$ -nitronaphthalene, 14,  $52.5^\circ$ ; - $m$ -dinitrobenzene, 52.5,  $65.5^\circ$ ; -1,3,5-dinitroanisole, 55,  $77.6^\circ$ ; -1,2,4-chlorodinitrobenzene, 25,  $44.5^\circ$ ; -sym-trinitrobenzene, 55,  $73.7^\circ$ ; - $\alpha$ -trinitrotoluene, 42.5,  $62.8^\circ$ ; -naphthalene, 20,  $77.3^\circ$ ; -dimethyldiphenylurea, 57,  $77.4^\circ$ ; -diethyldiphenylurea, 53-4, approx.  $52.1^\circ$ . Nitroerythritol- $p$ -nitrotoluene, 47,  $32.4^\circ$ ; - $m$ -dinitrobenzene, 70,  $42.4^\circ$ . Pentaerythritol nitrate- $p$ -nitrotoluene, 10,  $50.2^\circ$ ; - $p$ -nitroanisole, 5,  $50.8^\circ$ ; - $\alpha$ -nitronaphthalene, 4,  $55.1^\circ$ ; - $m$ -dinitrobenzene, 20,  $82.4^\circ$ ; -1,3,5-dinitroanisole, 20,  $94.7^\circ$ ; -1,2,4-chlorodinitrobenzene, 3,  $49^\circ$ ; -sym-trinitrobenzene, approx. 30,  $101.1^\circ$ ; - $\alpha$ -trinitrotoluene, approx. 13,  $76.1^\circ$ ; -naphthalene, approx. 7,  $79.1^\circ$ ; -dimethyldiphenylurea, 32.5,  $102.7^\circ$ ; -diethyldiphenylurea, approx. 12,  $68^\circ$ ; mannitol nitrate-erythritol nitrate 18.5,  $57.6^\circ$ ; pentaerythritol nitrate-mannitol nitrate, 20,  $101.3^\circ$ ; pentaerythritol nitrate-erythritol nitrate, approx. 5,  $59.5^\circ$ . Mannitol nitrate was the only compd. giving rise to mol. addn. compds. Probable compds. (detd. by extrapolation) are, in mols. per mol. of mannitol nitrate,  $p$ -nitrotoluene 2,  $p$ -nitroanisole 2,  $p$ -nitrophenetole 2,  $\alpha$ -nitronaphthalene 1. Bibliography. C. T. I.

Systems (a) ammonium  $d$ -tartrate-lithium  $d$ -tartrate-water and (b) ammonium lithium  $d$ -tartrate-ammonium lithium  $l$ -tartrate-water. Alan N. Campbell and Louis Slotin. *J. Am. Chem. Soc.* 55, 3061-70 (1933).—Soly. detns. were made at  $0^\circ$ ,  $30^\circ$  and  $60^\circ$  in the 2 ternary

systems  $\text{NH}_4 d\text{-tartrate-Li } d\text{-tartrate-water}$  and  $\text{NH}_4 \text{Li } d\text{-tartrate-NH}_4 \text{Li } l\text{-tartrate-water}$  to det. the effect on the transition temp. of the substitution of Li for Na in  $\text{Na NH}_4$  racemate. Filtration was accomplished through a sintered glass filter immersed in the thermostat. Li was detd. by ignition and conversion of the carbonate to sulfate while the  $\text{NH}_4$  was detd. by distn. A double salt,  $(\text{NH}_4)_2\text{Li}_2(\text{C}_4\text{H}_4\text{O}_6)_2$ , was formed at all 3 temps. The stability of this salt increased with the temp. In system (b) a true racemate was found at all 3 temps. having the formula  $(\text{NH}_4)_2\text{Li}_2(\text{C}_4\text{H}_4\text{O}_6)_2 \cdot \text{H}_2\text{O}$ . The transition temp. for  $\text{Li}_2\text{C}_4\text{H}_4\text{O}_6 \cdot 2\text{H}_2\text{O} \rightarrow \text{Li}_2\text{C}_4\text{H}_4\text{O}_6 + 2\text{H}_2\text{O}$  was detd. as  $21.52^\circ$  by the dilatometric method and as  $21.81^\circ$  by the soly. method. J. W. Shipley

The ternary system biphenyl-diphenylamine-benzophenone. H. Howard Lee and J. C. Warner. *J. Am. Chem. Soc.* 55, 4474-7 (1933); cf. C. A. 27, 889.—The f. p.-compn. diagram for the ternary system biphenyl-diphenylamine-benzophenone was detd. Two stable eutectics were found: (1) at  $18.8^\circ$  with the compn. 30.5 mols. % diphenylamine and 49.0 mols. % diphenylamine and (2) at  $16.5^\circ$  with the compn. 30 mols. % biphenyl and 52 mols. % benzophenone. Two metastable eutectics were found at the lower temps.  $15^\circ$  and  $13.1^\circ$ , resp., with slightly differing compns. H. S. van Kloooster

The system  $\text{CaO-FeO-SiO}_2$ . N. L. Bowen, J. F. Schairer and E. Posnjak. *Am. J. Sci.* 26, 193-284 (1933); cf. C. A. 27, 2867.—There are 3 ternary compds.  $\text{CaFeSiO}_5$  (hedenbergite), stable only below  $965^\circ$ , 2- $\text{CaO.FeO.2SiO}_2$  (Fe akermanite), stable below  $775^\circ$  and  $\text{CaFeSiO}_4$ . Only the last is stable at temps. where liquid is formed in any of the mixts. There are 30 invariant points. Seven of these are ternary but none is a eutectic, the min. temp. of existence of liquid in the system ( $1093^\circ$ ) being a point at which only 2 solid phases, both solid solns., are in equil. with the liquid. The outstanding feature of the system is the occurrence of solid-soln. series, the most important of which are the 2 metasilicate series and an orthosilicate series. The 1 metasilicate series extends from pure wollastonite ( $\text{CaSiO}_3$ ) to 76%  $\text{FeSiO}_3$ ; the other from hedenbergite ( $\text{CaFeSiO}_5$ ) to 80%  $\text{FeSiO}_3$ . Metasilicates with a higher content of  $\text{FeSiO}_3$  do not form, orthosilicate and tridymite appearing together as excess phases in such compns. The hedenbergite solid solns. are stable only at low temps. and are transformed at  $940-980^\circ$  to wollastonite solid solns. The principal orthosilicate solid solns. are Ca-Fe olivines, extending from fayalite ( $\text{FeSiO}_4$ ) through  $\text{CaFeSiO}_4$  to 59%  $\text{CaSiO}_3$ . Wollastonite solid solns. and Ca-Fe olivines occur together in equil. with some liquids of the system. The optical properties of the cryst. phases were measured and the variation of optical properties with compn. in the solid soln. series are shown. The x-ray diffraction patterns of members of the solid soln. series are reproduced. The bearing of the results upon the occurrence and compn. of natural minerals is discussed. Alden H. Emery

The homogeneous catalysis of gaseous reactions. The effect of iodine on the decomposition of acids, esters, ketones and halides. S. Baird and C. N. Hinshelwood. *J. Chem. Soc.* 1933, 1147-55.— $\text{I}_2$  has a very pronounced catalytic effect on the homogeneous decompn. of  $\text{HCOOMe}$  and  $\text{AcOMe}$  in the gaseous state. The catalyzed reactions are analogous to those of ethers and aldehydes (cf. C. A. 24, 5684). The decompn. of  $\text{HCOOH}$  and  $\text{AcOH}$  is not catalyzed by  $\text{I}_2$ . The catalyzed decompn. of  $\text{HCOOMe}$  proceeds mostly to  $\text{MeOH}$  and  $\text{CO}$ , the  $\text{MeOH}$  then decompn. principally to  $\text{CH}_4$ ,  $\text{H}_2\text{O}$  and  $\text{CO}$ . Neither Et halide nor ketone decompn. is appreciably catalyzed by  $\text{I}_2$ . P. H. Emmett

The homogeneous catalysis of gaseous reactions. The effect of iodine on the decomposition of simple aliphatic amines and of hexane. S. Baird and C. N. Hinshelwood. *J. Chem. Soc.* 1933, 1155-60; cf. preceding abstr.—The structural analogy between C-O-C and C-NH-C is reflected in a certain similarity between the catalyzed decompns. of the amines and the ethers. The amine reaction in the presence of  $\text{I}_2$  as a catalyst is explained.

qualitatively by the general equation  $RCH_2NHR' = R'H + RCH_2NH = R'H + RH + HCN$ . The intermediate aldimines enter into complex decompn. and condensation reactions that destroy any simple quant. relations. The H of the NH group plays no part in the amine decompn. since the decompn. of  $(C_2H_5)_2N$  and  $(C_2H_5)_2NH$  are both catalyzed and to about the same extent. The catalyzed decompn. of  $(CH_3)_2N$  and  $(CH_3)_2NH$  occurs about  $1/10$  as rapidly as that of the ethylamines. The effect of  $I_2$  on the decompn. of  $(C_2H_5)_2NH$  and of hexane is small. P. H. Emmett

**Polybasic acids as catalysts for the reduction of ammoniacal silver solutions by phosphorous acid.** Bruno Blaser. *Z. physik. Chem.* A166, 64-75(1933).— $HNO_3$  soln. of  $H_3PO_3$  shows little reduction of ammoniacal soln. of  $AgNO_3$ . Addn. of  $HPO_3$ ,  $H_3PO_4$ ,  $H_2P_2O_7$ , as well as  $H_2AsO_4$ , citric and aconitic acids shows marked catalytic effect on the reduction. Other acids show little effect. G. M. M.

**The role of ozone as catalyst of oxidation.** VI. The action of diluents of the ozone, of light and of catalysts of autoxidation. E. Briner and H. Biedermann. *Helv. Chim. Acta* 16, 1119-24(1933); cf. *C. A.* 27, 3389.—The oxidation of  $BzH$  by ozonized  $O$  was studied when the  $O_3$  was dild. with  $O_2$ ,  $N_2$  and  $CO_2$  as well as when it acted in the presence of a little  $O_2$  at 20 mm. pressure. The inert gas present aids the reaction to some extent, because the oxidation was markedly less in the low-pressure expts. Ultra-violet light does not seem to affect the oxidation with  $O_3$  although the total am $\phi$ . of oxidation is increased because of autoxidation. The same is true of  $Cu$  and  $Co$  salts, which catalyze autoxidation but retard the  $O_3$  reaction almost as much as mannitol. The oxidation with  $O_3$  seems to be entirely independent of autoxidation and unaffected by promoters thereof except insofar as availability of  $BzH$  may be diminished by a strong competing reaction. VII. The ozonization of dissolved hydriodic acid. *Ibid.* 1125-30; cf. Treadwell and Anner, *Z. anorg. Chem.* 48, 86(1906); Riesenfeld and Bencker, *C. A.* 11, 563.—No conclusive evidence could be obtained that  $O_3$  catalyzed the oxidation of  $HI$ . No yields of oxidation products above 83% were obtained, and dild. of  $O_3$  by inert gases did not reduce its activity to a marked extent. It seems probable that undissoc.  $HI$  is acted upon. The reaction is 30 times more rapid in  $HOAc$  than in aq. soln. R. Baltzly

**The physical state of solid catalysts.** Etienne Audibert and Andre Raineau. *Compt. rend.* 197, 596-8(1933).—Catalytically active  $Cu$  has a d. of about 7.6 instead of the normal value of 8.9 for massive material. Sintering by heating to about  $700^\circ$  raised the d. to the normal value. P. H. Emmett

**Specific catalytic surfaces.** E. K. Rideal. *Soc. Chem. Ind., Chem. Eng. Group, Proc.* 13, 45-9(1933).—Exptl. methods for detg. the sp. surface of a catalyst and for studying catalytic activity are discussed. P. H. E.

**The specific activity of catalysts.** E. B. Maxted. *Soc. Chem. Ind., Chem. Eng. Group, Proc.* 13, 43-5(1931).—The heat of adsorption of one of the reactants on a catalyst may supply the energy of activation required for the reaction being catalyzed. P. H. Emmett

**The reduction by hydrogen and the thermal decomposition of nitrides made by the reaction of ammonia with various promoted and unpromoted iron synthetic-ammonia catalysts.** P. H. Emmett and Katharine S. Love. *J. Am. Chem. Soc.* 55, 4043-50(1933).— $Fe_3N$  prepd. from active catalysts decomposes more rapidly than that prepd. from rather inactive catalysts. The energy of activation of the decompn. is about 50,000 cal. The rates and nature of the reduction and decompn. of the nitrides from the various  $Fe$  catalysts are given. P. H. Emmett

**The present status of the theory of ammonia catalysis.** W. Frankenburger. *Z. Elektrochem.* 39, 818-20(1933); cf. *C. A.* 27, 3561.—A reply to Kröger (*C. A.* 27, 5485) and a correction for the heat of formation of  $U_3N_4$  which is between 15 and 25 Cal./g.-atom  $N$  instead of 68.5 Cal. as previously stated. H. H. Rowley

**The heat conductivity of set masses of diatomaceous earth in relation to the specific weight and the amount of water added.** E. Raisch. *Gesundh.-Ing.* 56, 504-11(1933).—Curves show that the insulating properties of set mortar-like masses of diatomaceous earth increase with decrease in sp. wt. and also with increase in the amt. of water necessary to convert the powder into a mortar-like mass. Neither relation is linear. M. G. Moore

**Low-temperature specific heats.** I. An improved calorimeter for use from  $14^\circ$  to  $300^\circ K$ . The heat capacity and entropy of naphthalene. J. C. Southard and F. G. Brickwedde. *J. Am. Chem. Soc.* 55, 4378-84(1933).—An improved adiabatic "vacuum" calorimeter for solid and liquid substances is described, which can be used for studying slow transitions as well as measuring heat capacities with a precision of about 0.1%. From measurement of its heat capacity from  $14^\circ$  to  $300^\circ K$ , the entropy of naphthalene at  $25^\circ$  was calcd. to be  $39.89 \pm 0.12$  cal. mol. $^{-1}$  deg. $^{-1}$ . II. The calibration of the thermometer and the resistance of platinum, platinum-10% rhodium and constantan between  $-259^\circ$  and  $-190^\circ$ . J. C. Southard and R. T. Milner. *Ibid.* 4384-91.—A const.-vol. gas thermometer was used to measure the resistance of Pt, of Pt-10% Rh, and of constantan, in the range  $-259^\circ$  to  $-190^\circ$ , with an accuracy corresponding to  $\pm 0.02^\circ$ . A reference table of  $R/R_0$  for Pt from  $14^\circ$  to  $109^\circ K$ , and for constantan from  $14^\circ$  to  $20^\circ K$ , gives values for each degree. F. D. Rossini

**The heat capacities of gaseous mono- and dimethylamine.** W. A. Felsing and F. W. Jessen. *J. Am. Chem. Soc.* 55, 4418-22(1933).—A closed-system, continuous-flow calorimeter was used to measure  $C_p$ . By the Kundt method, the following values of  $C_p/C_v$  were found for  $25^\circ$ :  $CH_3NH_2$ , 1.202;  $(CH_3)_2NH$ , 1.149;  $(C_2H_5)_2N$ , 1.184;  $C_2H_5NH_2$ , 1.135. F. D. Rossini

**The heats of dilution of electrolytes.** G. Chapas. *Rev. gen. sci.* 44, 535-44(1933).—A review. F. D. R.

**The partial and integral heats of dilution of cadmium sulfate solutions from electromotive force measurements.** Victor K. La Mer and W. George Parks. *J. Am. Chem. Soc.* 55, 4343-55(1933).—The cell reaction  $Cd(satd. Hg) + PbSO_4(s) = CdSO_4(m) + Pb(satd. Hg)$  was re-investigated (cf. *C. A.* 25, 4767), and the conclusion that the Debye-Huckel parameter " $a$ " is 3.60 A. U. for concns. of  $CdSO_4$  of 0.0005 through 0.01 M and independent of temp. from  $0^\circ$  to  $30^\circ$  was definitely confirmed. Activity coeffs. of  $CdSO_4$  and thermodynamic quantities for the reaction are given. The concn. dependence of the relative partial molal and integral heat contents of  $CdSO_4$ , which were computed, is of the form demanded by the Gronwall, La Mer and Sandved theory. The partial molal heat capacity of  $CdSO_4$  is estd. to be approx.  $-200$  cal./deg./mol. at  $15^\circ$ . Allen S. Smith

**Calorimetric investigations. XXI. Heats of combustion of methyl-, ethyl- and phenyl-substituted succinic acids and of their anhydrides....(a) experimental data.** P. F. Verkade and H. Hartmann. *Rec. trav. chim.* 52, 945-68(1933).—The following are the isothermal heats of combustion at  $19.5^\circ$  at const. vol., per g. weighed in air with brass weights and expressed in 15° calories: succinic anhydride 3699.2, methylsuccinic acid 3903.3, methylsuccinic anhydride (solid) 4629.0, (liquid) 4647.3, asym-dimethylsuccinic acid 4591.0, asym-dimethylsuccinic anhydride, 5330.7, cis-sym-dimethylsuccinic acid 4607.7, trans-sym-dimethylsuccinic acid 4597.5, l-trans-sym-dimethylsuccinic acid 4599.6, cis-sym-dimethylsuccinic anhydride 5318.5, trans-sym-dimethylsuccinic acid 5304.6, trimethylsuccinic acid 5183.0, trimethylsuccinic anhydride 5884.2, tetramethylsuccinic acid 5681.4, tetramethylsuccinic anhydride 6356.9, ethylsuccinic acid 4588.7, ethylsuccinic anhydride (liq.) 5347.5, asym-diethylsuccinic acid 5653.7, asym-diethylsuccinic anhydride (liq.) 6393.7, cis-sym-diethylsuccinic acid 5672.1, trans-sym-diethylsuccinic acid 5662.4, cis-sym-diethylsuccinic anhydride (liq.) 6386.7, trans-sym-diethylsuccinic anhydride (liq.) 6376.5, triethylsuccinic acid 6434.9, tri-

ethylsuccinic anhydride (liq.) 7109.1, tetraethylsuccinic acid 7029.2, tetraethylsuccinic anhydride 7688.1, phenylsuccinic acid 5577.2, phenylsuccinic anhydride 6214.9, *cis-sym*-diphenylsuccinic acid 6690.7, *trans-sym*-diphenylsuccinic acid 6692.1, *trans-arym*-diphenylsuccinic anhydride 7202.5. The method of prepn. is given.

### 3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERT NOYLS, JR

Model of the electric field and of the photon. J. J. Thompson. *Phil. Mag.* 16, 809-45(1933). Theoretical. 3

E. J. Rosenbaum

Composition of atoms. A. Korn. *Scientia* 54, 240-51 (1933).—The possibility that atoms consist of 3 kinds of particles, pos. electrons, neg. electrons and gravitational particles, is briefly discussed. L. E. Gilson

Glow discharge at atmospheric pressure. H. Thoma and L. Heer. *Z. tech. Physik* 14, 385-8(1933); cf. *C. A.* 27, 911.—The cathode discharge portion of a glow discharge at atm. pressure obeys the similarity laws. The column shows the properties of glow discharge and produces no thermal ionization. Arthur Fleischer

Distribution of energies of electrons in gases. J. S. Townsend. *Phil. Mag.* 16, 729-44(1933).—Theoretical. Objections of Didlauskis (*C. A.* 27, 2374) are answered. The distribution of energies in electrons in gases is shown to be approx. Maxwellian. Even though the initial electron energies be the same, inequalities are produced by differences of the energy change in collisions with mols. 5

E. J. Rosenbaum

The passage of positive ions through gases. H. S. W. Massey and R. A. Smith. *Proc. Roy. Soc. (London)* A142, 142-72(1933).—The collisions of slow pos. ions with gas atoms are discussed in terms of a quantum mech. theory of collisions. For both elastic and inelastic collisions the relative motions of the centers of mass of the ions and atoms are treated as a perturbation. Correlation of exptl. results in terms of the theoretical formulas and agreement between observed and calcul. collision cross-sections are obtained. Nuclear symmetry is considered in the case of collisions of ions with similar atoms. Calvin Brous

The ionization of the noble gases by positive alkali ions (correction). J. Carlisle Mouzon. *Phys. Rev.* 44, 688 (1933).—A correction is made in the pressures used in former work (cf. *C. A.* 26, 5831). New data obtained in an app. of different design and with higher potentials agree with former work. A. B. F. Duncan

Studies of rare-gas-sodium arcs with the use of collectors. Tameo Harada. *Proc. Phys.-Math. Soc. Japan* 15, 371-83(1933).—The space charge, electron c. d. and electron temp. were detd. by the probe method for hot-cathode arcs of He, Ne, A, He + Na, Ne + Na and A + Na. These rare-gas-Na arcs resemble rare-gas arcs in the temp. interval from room temp. to 330° for He and 280° for Ne and A. Above these temps. the rare-gas-Na arcs resemble the Na arc, though some effect of the rare gas remains. E. J. Rosenbaum

A linear amplifier for the detection of corpuscles. Bruno Zipprich. *Z. Physik* 85, 592-617(1933).—The method uses the region where the self-consistent discharge in counters has not yet set in and therefore the no. of ions after multiplication is proportional to the primary no. (Townsend's theory). If electrode distance, gas pressure and field strength are suitably chosen the amplifier counts  $\beta$ -particles quantitatively. E. B.

The action of internal charges on the functioning of a Geiger-Müller counter. R. Brunetti and Z. Ollano. *Nuovo cimento* 10, 189-97(1933).—The excessive no. of impulses observed when a counter is exposed to x-rays (*C. A.* 27, 3396) is also found when the polarity of the

wire is reversed. The effect is ascribed to the emission of soft radiation by the metal of the counter. J. B. A.

Inner potential of metals. James A. Darbyshire. *Phil. Mag.* 16, 761-75(1933).—The diffraction of high-speed electrons by freshly cleaved surfaces of Sb, Zn, Bi and Te was studied. The deviation from the Bragg position of the beams diffracted by Sb and Zn was used to calc. the  $\pi$  and the inner potential. The values found were 12 v. for Sb and 15.5 v. for Zn. The results were not definite with Bi because of the presence of a cross-grating pattern. With Te the diffracted beams were in the undeviated Bragg position. E. J. Rosenbaum

Cuprous oxide photoelectric cells—a contribution to the space-charge photoeffect. W. Bulian. *Physik. Z.* 34, 745-56(1933).—The metal of the other electrode has no influence upon the selective max. On a gold-dusted electrode the direction of the photocurrent depends upon the wave length of the light. The optimum thickness of  $Cu_2O$  is 0.1 mm. Curves showing the temp. effect are given. Gregg M. Evans

Liberation of electrons from surfaces by ions and atoms. H. Kallmann and A. Rostagni. *Nature* 132, 567-8 (1933).—The no. of electrons emitted by metal surfaces bombarded by gaseous ions approached a limit as the voltage decreased. The no. from at. bombardment, however, decreased sharply with the voltage. At low velocities the no. is roughly proportional to the ionization potential. Gregg M. Evans

Remark on the paper by J. H. de Boer and M. C. Teves: Thermal and photoelectric emission from cesium cesium oxide cathodes and the effect of inserting cesium atoms in the dielectric. P. Görlich. *Z. Physik* 85, 128-30(1933); cf. *C. A.* 27, 4728.—A much higher quantum yield of photoelectrons is obtained if Cs atoms are embedded in a thick layer of  $Cu_2O$  instead of adsorbed on the surface of  $Cu_2O$ . Egon Bretscher

The electronic work function and the photoelectric properties of metals. P. I. Lukirskii. *Physik. Z. Sowjetunion* 4, 212-38(1933); cf. *C. A.* 26, 3990a.—A review of the energy relations at clean and coated metal surfaces. L. W. Elder

The influence of adsorbed gas films on the photoelectric sensitivity. Bernhard Abendroth. *Z. Physik* 85, 530-44 (1933).—Pt or CdI<sub>2</sub> carefully freed from adsorbed gas is photoelectrically inactive. Adsorption of small amounts of water, pyridine, propionic acid or benzene increases the photoelec. yield enormously; larger amts. diminish it. The effect is independent of the chem. nature and the dipole moment of the activator. Egon Bretscher

The inelastic scattering of slow electrons in gases. III. F. H. Nicoll and C. B. O. Mohr. *Proc. Roy. Soc. (London)* A142, 320-32(1933).—A description is given of an app. for studying the inelastic scattering in gases of electrons whose energies lie within a few v. of the excitation potential. Results have been obtained for H<sub>2</sub>, He and A for an angular range of 10-155° and a voltage range of 3-80 v. above the excitation potential. The curves for the inelastic scattering in A show diffraction effects at large angles which are similar to those that appear in the elastic scattering, but which disappear as the energy of the electrons approaches the excitation potential of the gas. The curves for H and He do not exhibit any

unusual features for low-velocity electrons, and the significance of the curves is discussed. Unlike the elastic scattering, the inelastic scattering at small angles (between  $10^\circ$  and  $30^\circ$ ) is seen to agree in form fairly well with that given by the Born formula down to relatively low velocities.

**Absorption effects in the total secondary electron emission from metal faces.** S. Ramachandra Rao. *Current Sci.* 2, 93-4 (1933); cf. *C. A.* 26, 5490.—Secondary electron emission ( $R$ ) and voltage ( $v$ ) give a linear relation when  $\log_e R/v$  is plotted against  $v$ . The slope is  $-(1 + \beta\alpha)B/2.3026$ , where  $\alpha$  and  $\beta$  are the coeffs. of absorption of primary and secondary electrons, resp., and  $B$  is the const. of variation. The equation is valid at potentials above 250 v.

**Electron diffraction and molecular structure—carbonyl compounds.** Ralph W. Dornte. *J. Am. Chem. Soc.* 55, 4126-30 (1933); cf. *C. A.* 27, 4999.—By means of electron diffraction the mol. structure of COS is proved to be linear;  $\text{COCl}_2$ ,  $\text{COBr}_2$ ,  $\text{AcCl}$  and  $\text{AcBr}$  are represented by plane "Y" models. In the first 2 compds. an angle of  $110^\circ$  was found between the halogen atoms; the tetrahedral model was found for the latter 2.

**Diffraction of slow electrons by single crystals of graphite.** V. E. Lashkarev, F. W. Barendsen and G. A. Kuzmin. *Z. Physik* 85, 631-40 (1933).—The diffraction of electrons of 6150 v. energy gives 7 maxima. Some must be forbidden. A constant inner potential of 20 v. agrees best with the exptl. results.

**Electron-diffraction investigation of the molecular structure of cyanogen and diacetylene with a note on chlorine dioxide.** L. O. Brockway. *Proc. Nat. Acad. Sci.* 19, 808-74 (1933).—The interatomic distances are:  $\text{C}-\text{N} = 1.16 \pm 0.02$ ,  $\text{C}-\text{C} = 1.43 \pm 0.03$  for cyanogen, for diacetylene  $\text{C}-\text{C} = 1.21 \pm 0.02$ , except for the center one, which is  $1.43 \pm 0.03$ . For  $\text{ClO}_2$  (cf. *C. A.* 27, 4999) the  $\text{Cl}-\text{O}$  distance should be  $1.53 \pm 0.08$ .

**Electron-diffraction investigation of the structure of molecules of methyl azide and carbon suboxide.** L. O. Brockway and Linus Pauling. *Proc. Nat. Acad. Sci.* 19, 860-7 (1933).—The accepted structure is  $\text{H}_3\text{C}-\text{N}=\text{N}$ , with the  $\text{CH}_3$  offset from the  $\text{N}$  line at an angle of  $135 \pm 15^\circ$ . The interat. distances are from left to right, 1.47, 1.26 and 1.10 Å. U.,  $\pm 2\%$ . Results for  $\text{C}_3\text{O}_2$  are best in accord with the simple electrically neutral structure  $\text{O}:\text{C}:\text{C}:\text{O}$ , with the interatomic distances  $\text{C}-\text{O} = 1.20 \pm 0.02$  and  $\text{C}-\text{C} = 1.30 \pm 0.02$  Å. U.

**Electron diffraction patterns from platinized asbestos.** D. A. Richards. *Phil. Mag.* 16, 778-87 (1933).—A sample of asbestos was platinized a no. of times by satg. in  $\text{PtCl}_4$  soln. and reducing in a stream of  $\text{H}$  at  $100^\circ$ . After each platinization the electron diffraction pattern was obtained. After 26 platinizations only the asbestos pattern was obtained, though the sample was colored black. After the 27th platinization faint Pt rings were obtained, while after the 29th only the Pt lines were obtained. The ratio of asbestos to Pt when the Pt pattern appears is 1.18 by wt. The observed facts are accounted for by the deposition of the Pt in cracks in the asbestos. Addnl. platinization then causes more splitting of the asbestos, probably during the process of reduction. When the Pt surface becomes comparable with the asbestos surface the Pt pattern appears.

**The refractive power of quartz glass in the short-wave infra-red.** C. Müller and A. Werthauer. *Z. Physik* 85, 559-60 (1933).—The  $n$  of quartz glass varies from 1.442 for  $0.511 \mu$  to 1.428 for  $2.595 \mu$ . A quartz prism was used for the detn. of  $n$ .

**Magnetic deflection of hydrogen molecules and the magnetic moment of the proton.** I. R. Frisch and O. Stern. *Z. Physik* 85, 4-16 (1933).—The magnetic deflection of para- and ortho- $\text{H}_2$  and ordinary  $\text{H}_2$  is studied at  $-195^\circ$  and ordinary temp. The deflection depends on the magnetic moment of the mol. This consists generally of 2 parts:  $\mu_r$  due to the rotation of the mol. and  $\mu_n$  resulting from the nuclear spin of the protons.

For para- $\text{H}_2$   $\mu_r$  is 0 at  $-195^\circ$  because the rotation quantum no. is 0,  $\mu_n = 0$  as the proton spins are antiparallel. The  $\mu_r$  of ortho-hydrogen is infinite at low temps. as the lowest state of rotation has the quantum no. 1.  $\mu_n$  is equal to 2 magnetic proton moments. Though the nuclear spin and the magnetic moment due to the rotation are perfectly uncoupled in the high magnetic field (20,000 gauss) used, the Maxwell distribution of velocity blurs the deflection patterns to such an extent that  $\mu_r$  and  $\mu_n$  cannot be detd. from 1 expt. The deflection for para-hydrogen is therefore measured at higher temp. when the rotation quantum no. is 2 and 4. This permits detn. of the moment due to rotation only. By combining with the results for ortho-hydrogen the magnetic moment of the proton is found not to be 1 but to lie between 2 and 3 nuclear magnetons ( $2 \times e/2mc \times \frac{1}{2} \times h/\pi$ ,  $m$  being the mass of the H atom). II. I. Estermann and O. Stern. *Ibid.* 17-24.—The expts. above are repeated with increased precision to det. the strength and inhomogeneity of the magnetic field. The  $\mu_r$  is found to be 0.8-0.9 nuclear magnetons and the magnetic moment of the proton times 2.5 the same unit. A supplement contains sample calcs. of intensities of the deflected beam.

**The magnetic moment of the rotating hydrogen molecule.** G. C. Wick. *Z. Physik* 85, 25-8 (1933); cf. *C. A.* 27, 4144.—The rotatory magnetic moment calcd. for a rigid  $\text{H}_2$  mol. differs from the experimentally detd. value (cf. prec. abstr.). The discrepancy diminishes if the perturbation of the electron movement due to the rotation is taken into account. The theory gives only the limits of 0.9 and 0.31 nuclear magnetons. The result is very sensitive toward errors of the proper functions used for the calcn.

**A new method of intensity measurement of molecular rays.** I. Estermann and O. Stern. *Z. Physik* 85, 135-43 (1933).—A new method of intensity measurement of wide applicability is based on the observation made by Langmuir and Kingdon (*C. A.* 17, 925) that the neg. space charge in the neighborhood of a glow cathode is partly destroyed by pos. ions. The mol. ray whose intensity is to be detd. enters a chamber contg. a W glow cathode which is negatively charged with respect to the cage. The mols. are ionized there and cause an increase of current which serves as a measure of the intensity of the mol. The method was tested with a  $\text{Hg}$  ray, whose pressure corresponded to  $\text{Hg}$  at  $-30^\circ$ . Benzophenone has also been used successfully.

**The magnetic deflection of oxygen molecules.** Robert Schürmann. *Z. Physik* 85, 212-30 (1933).—The magnetic deflection of  $\text{O}_2$  rays leads to a magnetic moment of 2 Bohr magnetons and to a coupling between the spin of the electrons and the angular momentum of the mol. The intensity of the  $\text{O}_2$  ray was measured by the method given in *C. A.* 23, 2386.

**Magnetic susceptibility of argon according to measurements by A. Roth.** Walther Gerlach. *Z. Physik* 85, 545-7 (1933).—Abs. susceptibility measurements of Ar between  $290^\circ$  and  $700^\circ$  lead to the value  $H = -19.72 \times 10^{-6}$  per g. atom, with a precision higher than 1% ( $H$  remains const. in the temp. range studied).

**Remark on the paper by R. Deaglio: Photoeffect in single crystals of cuprite.** G. Monch and R. Stühler. *Z. Physik* 85, 131-4 (1933).—The explanation of the photoeffect of cuprite suggested by D. (*C. A.* 27, 4728) is considered unsound on the basis of new expts.

**The neutron (Bakerian lecture).** J. Chadwick. *Proc. Roy. Soc. (London)* A142, 1-25 (1933); cf. *C. A.* 27, 1816.—In a survey of recent progress in the study of the neutron the following facts are brought out. Only bombardment of nuclei with  $\alpha$ -particles has been successful in the production of neutrons, the emission of the neutrons being accompanied by the capture of the  $\alpha$ -particle.  $\text{Al}$  and  $\text{Al}$ , although pure, emit both protons and neutrons forming either  $\text{Ne}^{23}$  or  $\text{Na}^{23}$ . Curves giving the dependence of the neutron emission on the  $\alpha$ -particle ve-

locity indicate a slight resonance level at  $2.4 \times 10^6$  electron v. for B and  $2$  at  $1.4 \times 10^6$  and  $2.5 \times 10^6$  electron v. for Be with potential barrier heights of  $3.7 \times 10^6$  electron v. for B and  $3.5 \times 10^6$  electron v. for Be. The mass of the neutron as computed from B disintegration is found to be 1.0067 with an upper limit of 1.0070 given by the neutron formation from Li and a lower limit of 1.0058 deduced from the mass of  $H^1$ . The fundamental nature of the neutron is still uncertain. Besides taking part in elastic nuclear collisions neutrons are able to disintegrate N, O and C and there is some evidence that they can produce positrons. Morris Muskat

Remarks on the subject of neutrons. Jean Perrin. *Compt. rend.* 197, 628 31(1933).--A discussion of recent ideas concerning the neutron and positron. An application of these ideas is made to the decompn. of neutrons into photons in stars and to the reverse process in interstellar space. Part of the cosmic rays at least seem to be identical with photons from neutron disintegration.

A. B. F. Duncan  
The neutron in quantum mechanics. B. M. Sen. *Nature* 132, 518(1933).--Math. By use of Dirac's relativity equation, the neutron can be properly placed in the scheme of the wave-mech. theory. If the value of  $r$  obtained ( $1.9 \times 10^{-11}$  cm.) does not agree with the present suggested radius of the neutron ( $10^{-12}$  cm.), it may be of interest as the lower limiting distance permitted under the Coulomb force. Calvin Broun

The excitation of neutrons from beryllium. Gilberto Bernardini. *Z. Physik* 85, 555-8(1933).--The intensity of neutron radiation escaping from Be on bombardment with  $\alpha$ -rays from Po is detd. with an ionization chamber contg.  $CH_4$  of 17 atm. as a source of protons. The neutron intensity is correlated with the range of the  $\alpha$ -rays (varied by change of  $CO_2$  pressure). A max. is found at 19 mm. air equiv. and a min. at 26 mm. The results are in agreement with observations by Rasetti (C. A. 27, 896) and Curie and Joliot (C. A. 26, 2021) and in contradiction with Kirsch and Slonek's results (C. A. 27, 2091).

Egon Bretscher  
Constitution of atomic nuclei. Sisaku Shimasaki. *Proc. Phys.-Math. Soc. Japan* 15, 384 99(1933).--On the assumption that nuclei are composed of  $\alpha$ -particles, ( $\alpha/2$  + neutron) particles and neutrons, the constitution and some other properties of nuclei have been deduced. The Fermi statistics yields the no. of  $\alpha$ -particles in nuclei. The outer electron configuration depends on the nuclear constitution. A nucleus formed by the addn. of an  $\alpha$ -particle is more stable than one formed by the addn. of a ( $\alpha/2$  + neutron) particle. The change of mass defect with at. no. is calcd. E. J. Rosenbaum

Nuclear radii and atom disintegration yields by heavy elements. G. Kirsch. *Naturwissenschaften* 21, 640 (1933).--Expts. of Merhaut and Wallner by the Schmidt scintillation method (*Sitzber. Akad. Wiss. Wien*, 134, 385(1925)) on the reflection of Ra C  $\alpha$ -particles by the elements Ag to Te showed abnormality. Odd-no. elements (In and Sb especially) have concave absorption curves; even-no. elements (Te, Zn, Cd) have a step in the curve. An explanation for this is the Curie-Joliot effect: atom disintegration with neutron emission. Recent expts. by Matzner have confirmed this opinion. Disintegration with neutron emission can be obtained even for the heaviest elements by Po  $\alpha$ -rays. A glass ball filled with emanation and Zn powder gives as a neutron source an effect 50 times that of Be irradiated with Po. It is concluded that the abnormal curves for  $\alpha$ -ray reflection indicate shortening in range of certain groups; disintegration of atoms by Ra C  $\alpha$ -particles with neutron instead of proton liberation is a general possibility. This conclusion is contradictory to the Gamov nuclear model with a Coulomb potential rise at a distance less than  $10^{-12}$  cm. from the nucleus; nuclear radii of 5 times larger size are to be assumed. B. J. C. van der Hoeve

Atom disintegration by cosmic radiation. J. Barnóthy. *Z. Physik* 85, 201-9(1933).--The discussion of Hoffmann collisions shows that the nuclear cross section for collisions as calcd. from Møller's formula disagrees with

expts. If a suitable nuclear model is assumed even, the largest of the Hoffmann collisions can be explained with the experimentally detd. primary energies. E. G. Steinke. *Ibid.* 210-11.

Egon Bretscher  
Fluctuation measurements of the cosmic radiation. II. W. Messerschmidt. *Z. Physik* 85, 332-5(1933).--The fluctuations of the cosmic radiation, which persist when corrections have been made for the variation of air pressure during the period of observation, can partly be correlated to variations of the earth magnetic intensity. The cosmic-ray intensity increases when the magnetic field decreases. Radiation filtered by 20 cm. Pb does not possess this dependence on the fluctuations of the magnetic field. Egon Bretscher

The absorption of penetrating radiation in water and the analyses of the absorption function. Walter Kramer. *Z. Physik* 85, 411-34(1933).--The absorption measurements of the cosmic radiation in water by Regener (C. A. 23, 2648; 26, 3179) are supplemented by observations in water depths from 0 to 20 m., as R. measured the absorption from 30 to 60 m. It is not possible to represent the absorption curve either by a superposition of exponential functions or by functions obtained by integration of the exponential over a hemisphere if homogeneous intensity of incidence is assumed. Agreement with expt. is obtained if the function calcd. by Kulenkampff (C. A. 24, 547) is used which takes into account the scattered radiation by the Compton process. Four components of different absorption coeffs. are sufficient to satisfy the exptl. figures very satisfactorily. The energies of the radiation calcd. from the Klein-Nishina formula are for the 4 components 6.4, 1.5, 0.65 and  $0.16 \times 10^6$  electron v., if only the external electrons are supposed to scatter. Egon Bretscher

The internal conversion of  $\gamma$ -rays. II. H. M. Taylor and N. F. Mott. *Proc. Roy. Soc. (London)* A142, 215 36(1933); cf. C. A. 27, 896.--Math. If a  $\gamma$ -ray escaping from a nucleus be represented by an electromagnetic wave, there is no equivalence between the loss of intensity of the wave in passing through the K ring and the no. of electrons ejected. The intensity change is generally small, even when the no. of electrons ejected is comparable with the no. of  $\gamma$ -ray quanta emitted. The ratio,  $b/g$ , of electrons to  $\gamma$ -quanta which is observed is found to replace the "internal conversion coeff.,"  $b/(g + b)$ , used in previous calcs. Agreement with expt. in the Ra B region is slightly less good than before; the alteration is negligible for Ra C. Calvin Broun

Separation of the isotopes of hydrogen. C. H. Collie. *Nature* 132, 508-9(1933).--With 10% KOH current densities must be kept below 0.1 amp./sq. cm., but with 0.3% as high as 0.5 amp./sq. cm. may be used successfully. In acid soln., with Pb electrodes, 10 l.  $H_2O$  was reduced to 1 ml. in 3 stages with the attainment of 40%  $H^1$ . The sepn. occurs when the  $H$  ion itself is discharged. Gregg M. Evans

The Allison magneto-optic effect. L. B. Snoddy. *Phys. Rev.* 44, 691(1933).--Preliminary note on modification of original Allison app. to obtain high-frequency oscillations in the spark-gap discharge. The same minima are obtained as formerly, but are sharper.

A. B. F. Duncan  
The isotopes of H by the magneto-optic method. The existence of  $H^1$ . Wendell M. Latimer and Herbert A. Young. *Phys. Rev.* 44, 690(1933).--A new minimum is found in solns. of HCl and HBr in water contg. 2-4%  $H^1$  and is ascribed to  $H^1$ .

A. B. F. Duncan  
Analysis of the long-range  $\alpha$ -particles from Ra C' by the magnetic focusing method. Lord Rutherford, W. B. Lewis and B. V. Bowden. *Proc. Roy. Soc. (London)* A142, 347-61(1933).--The long-range  $\alpha$ -particles from Ra C' have been measured with accuracy by an annular ring magnet and have been analyzed into 11 distinct groups. The corresponding energy levels of the excited nucleus have been deduced with certainty. All the prominent  $\gamma$ -rays may be correlated with these levels if 4 other levels which do not correspond with observed  $\alpha$ -particle groups are postulated. The relative intensities

of the  $\alpha$ -ray groups and the  $\gamma$ -rays show marked variations, which suggests the importance of dividing the  $\gamma$ -rays into the 2 types, dipole and quadrupole, and quantum numbers have been tentatively assigned to the levels.

Morris Muskat

$\gamma$ -Ray radiographic testing. Gilbert E. Doan. *J. Franklin Inst.* 216, 351-85(1933); cf. *C. A.* 27, 5001.

C. K. P. Jeffreys

Extraction of radium from Great Bear Lake pitchblende. R. J. Traill. *Trans. Can. Inst. Mining Met.* 1933 (in *Can. Mining Met. Bull.* No. 257) 448-67; cf. *C. A.* 27, 2876.—The history of Ra production and the principal processes for its extn. are outlined. Two distinct types of pitchblende ores occur. For high-silica pitchblende, the ore is leached with 20% HCl at 90° with const. agitation for 3 hrs. A soln. of  $\text{NaNO}_3$  is added in such a manner that oxidation will not be too rapid nor frothing excessive. The amt. of acid and nitrate required is governed by the compn. of the ore. After a 5-hr. leach, the batch is filtered hot and the residue is washed. While still warm,  $\text{BaCl}_2$  and  $\text{Na}_2\text{SO}_4$  are added to the filtrate, agitated and cooled. After agitation for 24 hrs., Ra- $\text{BaSO}_4$  and  $\text{PbCl}_2$  settle and are removed by filtration. A weak acid wash removes U and base-metal chlorides. The washed ppt. is treated with hot brine to remove  $\text{PbCl}_2$ . The residue of Ra- $\text{BaSO}_4$  goes to the refinery. For pitchblende in a carbonate-barite gang, the ore is roasted to 750-800°, ground, leached with HCl for 3 hrs., filtered and washed with hot  $\text{H}_2\text{O}$  to remove Pb salts. From the cooled filtrate  $\text{PbCl}_2$  and  $\text{AgCl}$  are recovered by filtration and U is obtained from the filtrate. The insol. residue of the first filtration, contg. Ra, Ba, Ag and  $\text{SiO}_2$ , is leached with an alk. soln. of NaCN to dissolve Ag. The residue is heated with a boiling soln. of  $\text{Na}_2\text{CO}_3$  to convert the Ra and Ba sulfates to carbonates. After filtration, a HCl leach removes the carbonates and leaves silica. The Ra- $\text{BaSO}_4$  is reprecip. with excess  $\text{Na}_2\text{SO}_4$  or  $\text{H}_2\text{SO}_4$ . After agitation for 24 hrs., they are settled and recovered by filtration.

Alden H. Emery

Action of  $\alpha$ -rays of polonium, of x-rays and of ultra-violet rays on nitrogen iodide and other explosives. Henri Muraour. *Bull. soc. chim.* 53, 612-13(1933).—Neg results were obtained with the action of these radiations on N iodide, picric acid, Pb picrate, trinitrotoluene, nitrocellulose, nitroglycerin and sym diethyldiphenylurea.

Howard Agnew Smith

A micro method for determination of the concentration of ortho-para hydrogen mixtures. A Farkas. *Z. physik. Chem.* B22, 344-9(1933). The usual heat cond. method for detg. the concn of ortho-para H mixts. was modified to enable measurements to be made on quantities as small as 1 cu. mm.

G. M. Murphy

A new method of measuring the intensity of Compton radiation. R. O. Wollan. *Helv. Phys. Acta* 6, 270-3(1933); cf. *C. A.* 27, 4165.

Egon Bretscher

The intensity of x-ray lines formed by irradiation of quadrupoles. Leo Pincherle. *Nuovo cimento* 10, 205-10(1933).—A math. derivation of the intensity ratio between lines due to quadrupole and those due to dipoles. The results applied to the spectrum of W show agreement with expt.

J. B. Austin

X-ray emission characteristic of elements in the gaseous state. K spectrum of xenon (emission and absorption). H. Hulubei and Y. Cauchois. *Compt. rend.* 197, 644-6(1933).—The  $K_\alpha$  and  $K_\beta$  lines of xenon were obtained and the absorption limit was measured. A table of  $L$ ,  $M$  and  $N$  levels of Xe is calcd. from the  $K$  values.

A. B. F. Duncan

X-radiation characteristic of elements in the gaseous state. Feeble rays in the K spectrum of krypton. Y. Cauchois and Horia Hulubei. *Compt. rend.* 197, 681-2(1933).—Kr at a pressure of 6 cm. was excited by electrons from a Lenard-Coolidge tube. The following lines were observed in the K spectrum:  $K\beta_1$ , 863.47 X. U.;  $K\beta_2$ , 864.34;  $K\beta_3$ , 869.04;  $\gamma$ , 872.71;  $K\delta_1$ , 876.68;  $K\delta_2$ , 877.19;  $K\delta_3$ , 881.40.

Gerald M. Petty

The  $K_{\alpha_1}$  doublet of phosphorus. Osvald Lundquist.

*Nature* 132, 518(1933).—The effect of chem. constitution on the  $K_{\alpha_1}$  doublet of P was studied. The emitting substances, excited by x-rays, were violet P, Na hypophosphite, and Na phosphate. Relative to the doublet of the free element the displacements to shorter wave lengths were for the hypophosphite doublet 1.7 X. U. and for the phosphate doublet 2.5 X. U.

C. B.

Weak lines in the L-spectrum from gold (79) to tungsten (74). Herbert Claesson. *Z. Physik* 85, 231-4(1933).—By use of the method of *C. A.* 25, 1155, new weak lines of the L spectra of Au and W corresponding to the transitions  $L_I - N_{IV}$  and  $L_{II} - N_{III}$  are observed.

Egon Bretscher

The influence of the chemical binding on the absorption coefficients of the lighter elements in the region of soft Röntgen rays. R. H. Messner. *Z. Physik* 85, 727-40(1933).—The absorptions of  $\text{H}_2$ ,  $\text{CH}_4$ ,  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{H}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{N}_2$ ,  $\text{O}_2$ ,  $\text{CO}_2$ , CO and air are detd. for the  $K_\alpha$  line of C (44.5 A. U.) and B (68 A. U.). A very definite and systematic influence of the chem. binding on the absorption coeff. is found. The  $Z^4$  and  $\lambda^3$  rule is valid for this spectral region, except for  $\text{H}_2$ , where the exponent is higher.

Egon Bretscher

Photometric methods of reflection of x-rays. I. Comparison of reflective powers of two crystals, by means of standard substance. Piedad de la Cievera and José Lozada. *Anales soc. españ. fis. quim.* 31, 607-15(1933).

The photometric method of measuring abs. intensities of x-rays was investigated. To operate independently of tube conditions which produce the rays, it is necessary to use a standard of comparison, e. g., a Debye Al line. By this method values of  $\rho$  were detd. wholly in accord with theoretical values.

E. M. Symmes

The thermal expansion of certain crystals with large lattices. Helen D. Megaw. *Proc. Roy. Soc. (London)* A147, 198-214(1933).—The expansion perpendicular to the cleavage plane of mica (phlogopite) has been detd., an complete detns. have been made of the thermal expansion of brucite, hydrargillite and  $\text{Ca(OH)}_2$ , by measuring with x-rays the change in lattice spacings between 0° and 100°. The hydroxides show marked anisotropy, the expansion coeff. perpendicular to the layer being greater than that in the layer.

Victor Hicks

Determination of the position of the hydrogen ions in the ammonium chloride lattice by diffraction of electron V. R. Lashkarev and I. D. Uyskin. *Z. Physik* 8, 618-30(1933).—The distance H-N in  $\text{NH}_4\text{Cl}$  is calc. from electron diffraction patterns to be  $0.95 \pm 0.07$  A. U. The  $\text{NH}_4$  radical is assumed to be a rotating tetrahedron.

Egon Bretscher

An x-ray study of *p*-diphenylbenzene. Lucy V. Pickett. *Proc. Roy. Soc. (London)* A142, 333-46(1933); *C. A.* 27, 2861.

*p*-Diphenylbenzene crystallizes in the monoclinic prismatic class with two mols. in the elementary cell with  $a_0 = 8.08$ ,  $b_0 = 5.60$ ,  $c_0 = 13.59$  A. U.,  $\beta = 91^\circ 55'$ . The space group is  $C_{2h}^2(P2_1/a)$ . The results of structure analysis by trial and error and by Fourier analysis indicate that the mol. is planar; that it consists of regular hexagons of carbon atoms 1.42 A. U. apart with probable sepn. of 1.48 A. U. between the hexagons and that its position may be given by rotations of 15° and 34° about the  $b$  and  $c$  axes, respectively, from an origin position in the (100) plane parallel to the  $c$  axis. Probable atomic positions are given.

Victor Hicks

Electrostatic deflection of positive electrons. Je. Thihaud. *Nature* 132, 480-1(1933).—When a source of pos. electrons was placed between 2 magnetic poles in the marginal region of non-uniform magnetic field the pos. particles described a cycloidal path to a recording film placed opposite the source. Application of an electric field displaced the spot by an amt. equal and opposite to the displacement for neg. electrons. The value of  $e/m$  for the pos. electron is therefore of the same order of magnitude as that for the neg. electron.

H. S. F.

Intensities in atomic spectra. M. H. Johnson. *Proc. Nat. Acad. Sci.* 19, 916-21(1933).—Theoretical.

C. C. Kies

Atomic multiplets in stellar spectra. L. M. Donnay. *Bull. sci. acad. roy. Belg.* 19, 755-69 (1933). C. C. K.

Neon absorption lines in stellar spectra. Donald H. Menzel and Roy K. Marshall. *Proc. Nat. Acad. Sci.* 19, 879-81 (1933).—Lines of Ne II have been found in absorption in the spectra of high-temp. stars of classes O and B. Thus Ne takes place with He as a gas of great abundance in the universe. C. C. Kiess

Identification of a certain number of lines observed in the spectra of the sun's disk and spots. P. Swings. *Bull. sci. acad. roy. Belg.* 19, 925-8 (1933).—Sixteen lines of  $Ba^+$  measured and classified by Rasmussen (C. A. 27, 4732) have been identified with faint lines in the disk and spot spectra of the sun. C. C. Kiess

The second spectrum of krypton. T. L. de Bruin, C. J. Humphreys, and Wm. F. Meggers. *Bur. Standards J. Research* 11, 409-40 (1933). The second spectrum of krypton (Kr II) has been selected from various Kr spectra excited in Geissler tubes by noting intensity changes accompanying variations of capacity and inductance in the elec. circuit. This description and analysis of the Kr II spectrum includes estimates of relative intensities and wave-length measurements for 1050 lines extending from 2080.53 Å. U. in the ultra-violet to 10,659.5 Å. U. in the infra-red. Most of these lines (71%) have been classified as combinations of 128 energy levels, 112 of which have been more or less definitely identified with quantum nos. and electron configurations. Zeeman effects are quoted for 102 lines. In addn., 51 lines in the extreme ultra-violet (575.92 to 964.93 Å. U.) are classified as transitions from excited states to the normal ones. The  $s^2p^6$  electron configuration of the normal  $Kr^+$  ion is represented by a doublet P term with level sepp. 5371  $cm^{-1}$ , and the excited states are described by doublet and quartet terms arising from the addn. of *ns*, *np*, *nd*, *nf* electrons to the  $s^2p^6$  group constituting the outer structure of the doubly charged ion ( $Kr^{++}$ ). An absolute value of 198,182  $cm^{-1}$  is derived for the ground level  $s^2p^6P^0_{1/2}$ , which fixes the ionization potential of  $Kr^+$  at approx. 24.4 v. W. F. Meggers

The dispersion of gases and vapors and their interpretation by the theory of dispersion. V. An interferometer for the Schumann region. G. Wolfsohn. *Z. Physik* 85, 366-7 (1933); cf. C. A. 27, 4733.—A Jamin-Mach interferometer with fluor spar plates is described. As the path of light is in vacuum, it can be used down to 1500 Å. U. Measurements of the anomalous dispersion of the Hg line 1850 Å. U. lead to an oscillator strength  $f = 1.3$ . Egon Bretschner

Extinction of the fluorescence of tellurium vapors by magnetic fields. Roman Smoluchowski. *Z. Physik* 85, 191-200 (1933); cf. C. A. 27, 5247.—The resonance series of Te is excited with Hg 4358 and 4046 Å. U. and the quenching effect of a magnetic field is investigated. The effect is different for the various series and the members of the same series. A possible explanation based on calcul. by Lenz and Condou (C. A. 23, 2046) is given. Egon Bretschner

The reversal of the direction of circular polarization of the fluorescence of thallium. W. Hanle. *Z. Physik* 85, 300-3 (1933); cf. C. A. 27, 662.—Light of 3776 Å. U. is passed into Tl vapors. The resonance line 3776 Å. U. and the green line 5300 are emitted. If the primary light is circularly polarized, the ultra violet line has the same sense of polarization, but the green line is polarized in the opposite direction. This is due to the different intensities of the Zeeman pattern components. Egon Bretschner

Probabilities of transition of the lines of the sharp and the diffuse series of thallium. A. Filippov and P. Prokoviev. *Z. Physik* 85, 647-60 (1933). K. B.

The nuclear moment of tin. H. Schuler and H. Westmeyer. *Naturwissenschaften* 21, 660 (1933).—Hyperfine structure was studied on the Sn II lines 4452.79, 6844.26, 5502.92, 5799.35 and 5589.44 Å. U. and it is concluded that the nuclear moments of  $Sn^{117}$  and  $Sn^{119}$  are  $I = -1/2$ , the  $\mu_N/\mu$  ratio is 2030 (from the  $6^3S^1/2$  term). The  $F$  level is reversed for the  $6^3S^1/2$  term of the odd no. of Sn isotopes in agreement with previous results (C. A. 27,

5640) and Kopfermann's results on Kr (C. A. 27, 5640). From the occurrences of magnetic moments only in nuclei of odd at. wt. it is concluded that an unpaired neutron or proton, not an unpaired  $\alpha$ -particle, is responsible. From the appearance of pos. or neg. moments in elements of odd at. wt. and even at. no. it is believed the neutron is more probable. It is possible for this neutron to have magnetic and mech. moments in the same or in opposite directions, probably because of its polarization. B. J. C. van der Hoeven

The magnetic moments of atom nuclei. H. Schuler and H. Westmeyer. *Naturwissenschaften* 21, 674-5 (1933).—Estermann, et al. (*Nature* 132, 170 (1933)) found for the magnetic moment of a proton  $2.5 \times 1/1840 (= 1/736)$  Bohr magnetons instead of  $1/1840$ . By tabulating first the known values for  $\mu/\mu_0$  by Fermi, Segré and Goudsmit for 12 elements or isotopes of odd at. no. and odd at. wt. having 1 proton in the nucleus (besides  $\alpha$ -particles and neutrons) (cf. preceding abstr.) a value of  $1/736$  is closely approximated; for those with an odd no. of neutrons (besides  $\alpha$ -particles) in the nucleus about  $1/2$  of this value is found. Secondly for 9 elements of even at. no. and odd at. wt., odd no. of neutrons, the value of  $\mu/\mu_0$  is near  $1/1840$  or half of this. It is concluded that the magnetic effects of the remainder of the nucleus are small as compared with those of the proton or the unpaired neutron probably because it is built like a crystal with only vibrational motions around fixed points. B. J. C. van der Hoeven

Perturbations in the barium I spectrum. G. O. Langstroth. *Proc. Roy. Soc. (London)* A142, 286-308 (1933).—A photographic method of photometry was used to measure the intensities of the lines in the Ba I multiplets which result from combinations of the  $2^1P$  and  $3^1D$  levels with higher  $^1D$  and  $^1F$  levels. Although individual lines show large departures from the normal intensities, because of mutual perturbations between terms of the same inner quantum no., yet it was found that the sum of the intensities of the lines, when arrayed into enlarged groups with the same  $\lambda$ , is in agreement with the theoretically predicted sum. C. C. Kiess

The Zeeman effect of the hyperfine structure of mercury line 2536 Å. U. A. Zvirionas. *Helv. Phys. Acta.* 6, 273-6 (1933).—Hyperfine component - 25.4 milli-Å. U. of 2536 Å. U. is isolated by the method of Mrozowski and the Zeeman effect stud. with an expl. arrangement similar to that used by Schwein (C. A. 22, 1541). The  $\pi$ -component of line - 8.5 milli-Å. U. is observed. Egon Bretschner

Hyperfine structure and nuclear moment of krypton. Hans Kopfermann and N. Wieth-Knudsen. *Z. Physik* 85, 353-9 (1933); cf. C. A. 27, 5640.—Kr 83 has a nuclear spin of  $7/2$  or more. A neg. magnetic moment is assumed for Kr 83 from the reversal of the order of the terms. The components of the even isotopes coincide with the center of gravity of the Kr 83 lines. Egon Bretschner

The nuclear moments of xenon. Hans Kopfermann. *Naturwissenschaften* 21, 704 (1933).—From hyperfine structure study of a no. of Xe lines it is concluded: (1) The mech. moment of  $Xe^{136} = 1/2$ , that of  $Xe^{131}$  probably  $= 1/2$ . (2) The even no. Xe isotopes (124, 126, 128, 130, 132, 134, 136) do not give split lines. The numerical ratio of  $\mu_{136}/\mu_{131} = 1.1$ ; the former is neg.; the latter is pos. The gravity centers for the lines of all isotopes coincide. B. J. C. van der Hoeven

Nuclear moment of tantalum. J. H. Givoli and P. Zeeman. *Nature* 132, 566 (1933).—The value of  $I = 7/2$  of Grace and MacMillan (cf. *Phys. Rev.* 44, 325 (1933)) is confirmed. Gregg M. Evans

Influence of temperature on absorption in excited mercury vapor. Osamu Masaki. *J. Sci. Hiroshima Univ., Ser. A* 3, 187-92 (1933).—Methods, previously described (C. A. 25, 2362) for measurement of absorption of lines from Hg in the presence of Ne, were extended to cover the range 2300-7000 Å. U. L. P. Hall

The spark spectrum of iron in the extreme ultra-violet. Leon Bloch and Eugene Bloch. *Compt. rend.* 197, 679-80 (1933).—The positions and intensities of 171 lines in the spectrum of Fe between 364 and 1149 Å. U. are reg.

ported. The positions of most of the lines are in fair agreement with those reported by Millikan, Bowen and Sawyer (*C. A.* 15, 1655); the intensities are widely divergent.

Gerald M. Petty  
The spectrum of the doubly ionized neon in the extreme ultra-violet. V. v. Keussler. *Z. Physik* 85, 1-3(1933). The combinations of the Ne (III) ground term  $2p^2P_{0,1,2}$  with  $3s(^4S)^1S_1$ ,  $3d(^4S)^1D_{1,3}$ ,  $3s(^2P)^1P_{0,1,2}$  are observed.

Egon Bretscher  
Wave length of the vacuum spark spectra of carbon, nitrogen and oxygen in the extreme ultra-violet. Bengt Edlen. *Z. Physik* 85, 106(1933).—Lines (1200) of the highly ionized atoms; C(I), C(II), C(III), C(IV), C(V), N(V), N(IV), N(III), N(II), O(VI), O(V), O(IV), O(III), are collected in tables. The wave lengths range from 104 to 1923 Å. U.

E. G.  
The ratio of oscillator strengths of the resonance lines of silver. A. Filippov and I. Islamov. *Z. Physik* 85, 409-10(1933).—From measurements of the anomalous dispersion of Ag vapor the ratio of  $f$ -values for the transitions  $5^2S_{1/2} - 5^2P_{1/2,3/2}$  is  $2.03 \pm 0.06$  in agreement with Fermi's theory.

Egon Bretscher  
The first spark spectrum of gold. Au II. B. V. Raghavendra Rao. *Proc. Roy. Soc. (London)* A142, 118-28 (1933).—Classifications are given for more than 150 lines of Au II between 6456 and 1378 Å. U. About 30 new terms, in addn. to those already known, have been found. Many of them arise from the electron configurations  $5d^9 6d$ ,  $5d^9 6s^2$ , and  $5d^9 6s 7s$ , but a few of them cannot be accounted for theoretically. C. C. Kiess

Probabilities of transition in the diffuse and sharp series of sodium. L. S. Ornstein and J. Key. *Z. Physik* 85, 565-7(1933).

Egon Bretscher  
Series of the alkalis in an electric field. E. Segrè and G. C. Wick. *Nuovo cimento* 10, 211-20(1933), cf. *C. A.* 27, 5245.—The intensity of permitted and prohibited lines in the spectrum of K in an elec. field is calcd. on the basis of forced ionization by a method analogous to that used for H by Lenzos (*C. A.* 25, 4181). The results appear to explain the vanishing of the higher members of the series observed experimentally in high fields (cf. Kulm, *C. A.* 24, 5615).

J. B. Austin  
The arc spectrum of cerium. Paul Karlson. *Z. Physik* 85, 482-503(1933). 540 lines of Ce I are shown to be combinations between 105 energy levels. K. gives the principal quantum no. for each level. The ground term of Ce I is an  $a^1H^0$  term with the configuration  $4f^5d1s^2$ . By using the next higher term  $b^1H^0$  the ionization potential is found to be 6.54 v. by extrapolation. L. R.

Under-water spark spectrum of cerium. J. S. Budani. *Indian J. Physics* 8, 19-25(1933). Measurements were made of the wave lengths of a no. of lines in the under-water spark spectrum of Ce; a 10-foot grating was used.

C. E. P. Jeffreys  
The spectrum of H<sub>2</sub>. The bands ending on  $2p^1\Pi$  levels. III. O. W. Richardson, P. M. Davidson, J. Marsden and W. M. Evans. *Proc. Roy. Soc. (London)* A142, 40-62(1933).—In continuation of previous work (*C. A.* 27, 2878) the bands of H<sub>2</sub> originating in the levels  $4d^1\Sigma_u$ ,  $4d^1\Pi_u$ ,  $4d^3\Pi_u$ , and  $4d^3\Delta_u$ , and terminating on  $2p^1\Pi_u$  are described. In the appendix theoretical values for the energy levels and intensities in the bands are calcd. from the wave mechanics and are found to be in agreement with the observed values. C. C. Kiess

The spectrum of H<sub>2</sub>. The  $3d^1\Delta$  and  $4d^1$  levels. O. W. Richardson and P. M. Davidson. *Proc. Roy. Soc. (London)* A142, 63-76(1933).—The  $3d^1\Delta_u$  levels of H<sub>2</sub> are now established through the bands that originate on it and terminate on  $2p^1\Sigma_u$  and  $2p^1\Pi_u$ . These new bands complete the  $3d^1\Sigma_u\Delta$  group and, from analogy with them, the previously known bands from the 4-electronic states are corrected, extended, and satisfactorily interpreted. These bands are the only ones known in the H<sub>2</sub> spectrum that break the selection rule  $\Delta A = 0$  or  $\pm 1$ , a violation which is theoretically accounted for. C. C. Kiess

The red titanium oxide system in  $\alpha_1$  Herculis. N. T. Hobronnikoff. *Astrophys. J.* 78, 211-18(1933).—In the spectrum of  $\alpha_1$  Herculis 86 bands of the transition

$^3E \rightarrow ^3E$  have been measured between 6292' and 8506 Å. U., including 11 bands of the —2 sequence not hitherto observed in lab. sources. C. C. Kiess

New investigations of the spectra of diatomic molecules of sulfur. M. L. Hubin. *Bull. sci. acad. roy. Belg.* 19, 770-88(1933).—New observations have been made of the fluorescence spectra of S<sub>2</sub> excited by ultra-violet Hg rays. From the new data and from observations by others the formula for the series has been recalcd. and is given as  $\nu = \nu_0 - 728.23 \nu' + 2.09 \nu'^2$ . The formula derived for the heads of the absorption bands of S<sub>2</sub> vapor is  $\nu = 32250.14 + 432.83 (\nu' + 1/2) - 2.93 (\nu' + 1/2)^2 - 730.92 (\nu' + 1/2) + 2.69 (\nu' + 1/2)^2$ . C. C. Kiess

Study of the variation with temperature and pressure of the absorption and fluorescence spectra of diatomic tellurium vapor. M. Migeotte. *Bull. sci. acad. roy. Belg.* 19, 789-808(1933).—From observations of the effect of temp. and pressure on the absorption and fluorescence spectra of Te<sub>2</sub> it was found: (1) that with const. pressure and increasing temp. the higher series members of the  $\nu'$  progressions are brought out in the absorption spectrum whereas in the fluorescence spectrum the higher members of the  $\nu'$  progressions are diminished in intensity; (2) that similar effects appear in both spectra when the pressure of the vapor is varied under const. temp. conditions. Theoretical interpretations of these results are derived from the kinetic theory of gases. C. C. Kiess

Quantization of the Kramers and Pauli model. P. M. Davidson. *Proc. Roy. Soc. (London)* A142, 269-72(1933). It is shown that the quantized motions which the old quantum theory permits in simple Kramers and Pauli diatomic models are not limited to those specified by the original authors. The present quantized motion and their energy formulas offer a close analogy to those given by the wave mechanics for the corresponding mol.

Morris Muskat  
The quantity of ozone in the planetary atmospheres. D. Eropkin. *Compt. rend. acad. sci. (U. R. S. S.)* 1933A 61-9.—Sec. C. A. 27, 3399. C. E. P. Jeffreys

Investigations in the infra-red region of the spectrum IX. The absorption spectrum of chlorine monoxide (Cl<sub>2</sub>O). C. R. Bailey and A. B. D. Cassie. *Proc. Roy. Soc. (London)* A142, 129-41(1933).—By methods the same as in previous work (*C. A.* 26, 5405) the infra-red spectrum of Cl<sub>2</sub>O was explored between 1  $\mu$  and 18  $\mu$ . Four bands were measured at 15.03, 10.28, 8.033 and 7.625  $\mu$ , of which the second is the only one with indication of a Q branch. In a consideration of the structure of the mol. based on various assignments of the fundamental frequencies, the rectilinear form is shown to be untenable and of the triangular form, that with vertical angl 108° is favored. The effect of the isotopes Cl<sup>35</sup> and Cl<sup>37</sup> is considered and is shown to account for the observed envelopes of the bands. C. C. Kiess

New band systems in the gadolinium oxide spectrum Giorgio Piccardi. *Nature* 132, 481(1933).—By photographing the spectrum of Gd oxide as excited by the oxyhydrogen flame, 2 new band systems were found in the blue region, with origins at  $\lambda$  4615.6 Å. U. and 4892.1 Å. U. These systems are very bright at the flame temp but disappear completely at the arc temp.

Helen S. Hopfield  
Theory of coordination bonds. III. Absorption band of complex salts. R. Samuel, A. Abdul Hafiz Khan and Nazir Ahmad. *Z. physik. Chem.* B22, 431-43(1933) (cf. *C. A.* 27, 2095).—The absorption coeffs. of aq. soln. of the following salts were measured: Cr(NH<sub>3</sub>)<sub>3</sub>(NO<sub>3</sub>), Cr(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>, Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>, Co(NH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>)<sub>3</sub>Cl, Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>, Ni(NH<sub>3</sub>)<sub>3</sub>Br<sub>3</sub>, K<sub>3</sub>TiF<sub>6</sub> and K<sub>3</sub>BeF<sub>6</sub>. A set of empirical rules is presented to explain the absorption curves. G. M. Murphy

Nature and spatial extent of the scattering moment in optically active molecules. Werner Kuhn and Kai Rein. *Z. physik. Chem.* B22, 406-22(1933).—Earlier considerations on the order of magnitude of the anisotropy factor are extended to cases where the scattering moment is assumed to have partly or wholly quadrupole-like characteristics. Earlier difficulties, such as the very wide

extent of the scattering moment in the mol., are removed by this refinement.

G. M. Murphy

**Fluorescence of gaseous formaldehyde.** S. Gradstein. *Z. physik. Chem.* B22, 384-94(1933).—At pressures of 50-100  $\mu$ m. the fluorescence spectrum of  $\text{H}_2\text{CO}$  with monochromatic light is independent of the absorption band used for excitation. This is attributed to collisions during the lifetime of the excited mol. that cause a transition into the vibrationless state of the excited electronic state. The vibrational transitions seem to be the forbidden ones of the Herzberg-Teller selection rules for vibrational transitions (*C. A.* 27, 4170). G. M. M.

The absorption spectra of solutions of iodine bromide, cyanogen iodide and cyanogen bromide. A. E. Gillam. *Trans. Faraday Soc.* 29, 1182-9(1933).—In earlier investigations the absorption spectra of  $\text{CCl}_4$  solns. of the halogens (*C. A.* 23, 4887), and of  $\text{ICl}$  in other solvents (*C. A.* 25, 5091) were studied. Results of an investigation of the related compds.,  $\text{IBr}$ ,  $\text{CNI}$  and  $\text{CNBr}$  along similar lines are now described. Solns. are made with  $\text{CCl}_4$ ,  $\text{CHCl}_3$ , alc.,  $\text{EtOAc}$ ,  $\text{AcOH}$ ,  $\text{HBr}$  and  $\text{HCl}$ . The absorption spectra are detd. photographically, with Hüller E 3 quartz spectrographs and sector photometers, the light sources consisting of an Fe Ni arc in air, and a W spark under water. Absorption curves are plotted showing the molar extinction coeff. as a function of wave length, the concns. being of the order of 0.02 *M*. The results of this and previous work on the absorption spectra of the halogen and inter-halogen compds. in soln. show that  $\text{IBr}$  exhibits dichroism similar to that shown by  $\text{I}$  and  $\text{ICl}$ . The yellow solns. (e. g., in alc.) exhibit an absorption band with a max. near 400  $\mu$ , while the red solns. (e. g., in  $\text{CHCl}_3$ ) absorb similarly about 490  $\mu$ . The  $\text{HBr}$  and  $\text{HCl}$  solns. are different from those in the ordinary org. solvents, the absorption bands being due to  $\text{HBr}_2$  and  $\text{HBrCl}$ , resp., or their anions. The substances  $\text{Cl}_2$ ,  $\text{Br}_2$ ,  $\text{I}_2$ ,  $\text{BrCl}$ ,  $\text{ICl}$  and  $\text{IBr}$  exhibit broad unresolved bands of selective absorption in the visible or near ultra-violet. The compds.  $\text{CNI}$  and  $\text{CNBr}$  are practically transparent in these regions but both exhibit end absorption which may be part of a band with a max. below 220  $\mu$ . The substances  $\text{I}_2$ ,  $\text{ICl}$ ,  $\text{IBr}$  and  $\text{CNI}$  exhibit 1 or other of 2 absorption bands according to whether they are dissolved in "saturated" or "unsaturated" solvents (e. g.,  $\text{CHCl}_3$  and alc., resp.). This property had not so far been observed in any other of the above substances, and hence would appear to be exclusive to such of these compds. as contain  $\text{I}$ . This dichroism in the case of  $\text{I}$  has been attributed to the occurrence of solvation by certain solvents, with a corresponding change in absorption spectrum. It would therefore appear that the  $\text{I}$  mol. possesses "residual valency" which makes it capable of forming loose addn. compds. with certain types of solvent mols. The present results show that this residual valency persists even when 1 of the 2 atoms in the  $\text{I}$  mol. is replaced by any one of the radicals  $\text{Cl}$ ,  $\text{Br}$  or  $\text{CN}$ .

W. F. Meggers

**Absorption spectra of a series of organic molecular compounds.** W. H. Hunter and E. H. Northey. *J. Phys. Chem.* 37, 875-87(1933).—Quant. absorption curves in the region 6500-3000  $\text{\AA}$ . U. are given for the following compds.: chloroquinone (I), quinone (II), toluquinone (IK), xyloquinone (IV), duroquinone (V), and for equimol. mixts. of each with dimethylaniline (VI), hydroquinone dimethyl ether, and resorcinol dimethyl ether; I, II, III and V with veratrole and anisole (VII); I and III with *p*-xylene, mesitylene, durene, bibenzyl and tolan. The measurements were made on thin films of molten material in heated cells. The "solvents" affect each quinone in the same order and produce changes ranging from "solvent effects," e. g., VII, to color changes attributed to mol.-compd. formation (VI). The effect of "solvent" increases with increasing quinone oxidation and reduction potential, i. e., from V to I. J. E. A.

**Influence of ultra-violet absorption on the relative intensities of Stokes and anti-Stokes lines in the Raman spectrum.** S. C. Sirkar. *Indian J. Physics* 8, 67-75,

(1933); cf. *C. A.* 26, 1189.—The value of the ratio  $I_{\text{AS}}/I_{\text{S}}$  in the case of the 655 line due to  $\text{CS}_2$ , excited by the 4358-line, was detd. with blackening-log intensity curves obtained with the aid of a standardized W-ribbon lamp for comparison of intensities. The observed value of the ratio indicates the influence of the absorption frequency, and gives the value 1.776 for the factor  $(1 + 4\nu_{\text{vib}}/\nu)^2$ ,  $\nu_{\text{vib}}$  —  $\nu^2$  in the theoretical expression of Placzek.

C. E. P. Jeffreys

**Raman spectrum of gaseous carbon dioxide.** Arthur Adel. *Phys. Rev.* 44, 691(1933).—The prediction that 2 of the 6 lines obtained by Langseth and Nielsen (*C. A.* 27, 1272) were Raman lines of  $\text{CO}_2$  is supported by infra-red measurements of Barker and Wu (unpublished).

A. B. F. Duncan

**The Raman effect. XXVI. The Raman spectra of the methyl and ethyl esters of monobasic fatty acids.** K. W. F. Kohlrausch, F. Köppl and A. Pongratz. *Z. physik. Chem.* B22, 359-72(1933); cf. *C. A.* 27, 3669.—Raman spectra were obtained for the Me and the Et esters of formic, acetic, propionic, butyric, isobutyric, valeric, isovaleric,  $\alpha$ -methylbutyric, pivalic, caproic, isocaproic,  $\alpha,\alpha$ -dimethylbutyric, cnanthic and caprylic acids, methyl pelargonate and methyl caprate. XXVII. The Raman spectra of the esters of formic and chloroformic acids as well as acid chlorides. K. W. F. Kohlrausch and A. Pongratz. *Ibid.* 373-83.—Raman spectra were obtained for the propyl, isopropyl, butyl, isobutyl, secondary butyl, amyl and isoamyl formates, the methyl, ethyl, propyl, isobutyl and isoamyl chloroformates, and the acetyl, propionyl, butyryl, isobutyryl valeryl, isovaleryl,  $\alpha$ -methylbutyryl, pivalyl, caproyl, isocaproyl and  $\alpha,\alpha$ -dimethylbutyryl chlorides.

G. M. Murphy

**The Raman effect in terpene compounds. IV. The terpenes and the terpinolenes.** G. Dupont, J. Lévy and Mlle. Marot. *Bull. soc. chim.* 53, 393-406(1933); cf. *C. A.* 27, 2623.—The dehydration products of terpene or of terpinol were investigated by means of the Raman effect. The products obtained are, namely, cineole, together with dipentene, terpinene, and  $\alpha$ - and  $\gamma$ -terpinolene. Anhyd. ( $\text{COOH}$ ), yields with terpene, the products dipentene and  $\alpha$ -terpinene.  $\text{HCOOH}$ , ( $\text{COOH}$ ), and  $\text{Al}$  with terpinol yield the same compds., with increased proportions of terpinolene. The decompn. of terpenyl acetate yields a mixt. of limonene,  $\alpha$ -terpinene, and terpinolene. Dipentene and terpinene dihydrochlorides yield dipentene and  $\alpha$ -terpinene on removal of the acid chlorides. In addn. to these compds. other products result, as yet unidentified, which contain double bonds. The complete Raman spectra of the products are given when compared with the spectra obtained with the pure compds.

James H. Hibben

**Quantitative measurements of the total spectrum of technical radiation sources.** H. Krefit and M. Pirani. *Z. tech. Physik* 14, 393-411(1933).—Quant. measurements of tech. emission radiation from 0.2 to 10  $\mu$  are obtained by simultaneous use of prismatic resoln. and of filters and thermoelements. The app., calibration, and errors are discussed. Photoelec. cells are used to the near infra-red and thermoelements to the far infra-red. Spectral sensitivity is detd. by means of W ribbon lamps. The spectral characteristics of low-pressure: Na, Hg, Cd, Zn and high-pressure (200, 400, 800 mm.) Hg lamps are described.

Arthur Fleischer

**Dispersion measurements on sodium chloride in the long-wave infra-red region.** C. H. Cartwright and M. Czerny. *Z. Physik* 85, 269-77(1933).—The absorption coeff.  $k$  and the refractive index  $n$  are detd. from measurements of transparency  $D$  of  $\text{NaCl}$  crystals for light from 70 to 125  $\mu$ . As the theoretical formula for  $D$  contains  $n$  and  $k$  a second equation is necessary which is supplied by interference effects due to repeated reflection of the ray on the front and back plane of the crystal plate.

Egon Bretschier

**Absorption spectra of burning hydrocarbons.** A. Egerton and L. M. Pidgeon. *Proc. Roy. Soc. (London)* A142, 26-39(1933).—The ultra-violet absorption spectra

of vapors of alcs., aldehydes, acids, unsatd. hydrocarbons, peroxides, etc., that may be formed during combustion of a hydrocarbon, have been photographed and compared with the absorption spectra of various hydrocarbons undergoing slow combustion. It was found that during combustion the spectra of the hydrocarbons exhibit: (1) continuous absorption in the far ultra-violet down to the limit of the spectrograph at 2000 Å. U.; (2) bands beginning near 3500 Å. U. identified with those of formaldehyde; (3) in the higher hydrocarbons a band of continuous absorption with max. at 2800 Å. U. that makes its appearance in the spectrum before the aldehyde bands.

C. C. Kiess

The action of light on vapors of rubidium iodide. Manohar S. Desai. *Z. Physik* 85, 360-5(1933).—The following 4 regions of continuous absorption have been observed: 3700 Å. U. (77.3 kg.-cal.), 2900 (98.6) 2548 (112.2) and 2150 (133). The first process is a mere dissocn. into normal atoms with an energy of reaction of 78 kg.-cal. in agreement with that calcd. by Born's cycle. The second leads to a normal Rb and excited I atom, the third to an excited Rb and a normal I atom while Rb and I are excited in the last case. E. B.

Quantum yields of the photochemical reactions of phosgene. C. W. Montgomery and G. K. Rollefson. *J. Am. Chem. Soc.* 55, 4025-35(1933).—The quantum yield for the photochem. oxidation of phosgene under the conditions of this study is 1.80; for the phosgene-sensitized oxidation of CO a value of 87-110 was found; from a comparison of the rates of oxidation and reduction, for the photochem. reaction of phosgene and H was obtained a quantum yield of 3.8, corresponding to a time of 2 min.; this figure decreases with time. Mechanisms in accord with the observations are proposed for all of these reactions. For the latter reaction the theoretical rate expression  $d(\text{CO})/dt = kI_0(\text{COCl}_2)[1 + k(\text{H}_2)/(\text{CO})]$  ( $M$ ) is in accord with the exptl. facts. W. E. V.

Phosgene-sensitized oxidation of carbon monoxide. G. K. Rollefson and C. W. Montgomery. *J. Am. Chem. Soc.* 55, 4036-43(1933); cf. preceding abstr.—The phosgene-sensitized oxidation of CO was studied in the full light of a Hg arc. For low O pressures the rate expression was found to be  $d(\text{CO})/dt = kI_0^{1/2}(\text{COCl}_2)^{1/2}(\text{CO})^{1/2}(\text{O}_2)^{1/2}$ ; at higher O pressures it is  $d(\text{CO})/dt = kI_0^{1/2}(\text{COCl}_2)^{1/2}(\text{CO})^{1/2}$ . It is thought that very similar mechanisms will be found to apply to both the Cl- and phosgene-sensitized oxidations. W. E. V.

Decomposition of ethyl chlorothionoformate in the dark and under the action of light. A Berthoud and Daniel Porret. *Helv. Chim. Acta* 16, 930-42(1933). The decompn. of  $\text{CICSORt}$ , prepd. in 2 different ways, is completely unaffected by light. The decompn. is strongly accelerated by dimethylaniline. The temp. coeff. of the thermal decompn. is 3.2 in the temp. range 77-90° and 2.2 between 90° and 98°. E. J. Rosenbaum

Kinetics of the thermal and photochemical reaction between iodine and diazoacetic ester in carbon tetrachloride solution. W. B. S. Newling, L. A. K. Staveley, and E. A. Moelwyn-Hughes. *Trans. Faraday Soc.* 29, 1155-62(1933).—The velocity of this reaction was measured between 25° and 45° by titration with thiosulfate. Because of the interference of subsequent reactions, the initial stages of the reaction were studied chiefly. The initial reaction is bimol. and is accelerated by  $\text{H}_2\text{O}$ . If the reaction which regenerates I is unimportant at first, every activating collision leads to chem. change. Otherwise the efficiency is  $1/\infty$ . Light increases the rate approx. in proportion to the intensity. The quantum efficiency ( $\lambda = 5460$  Å. U.) increases with the initial concn. of I, reaching a limiting value of 2. E. J. R.

"Transmutation" of elements. Oxygen, sulfur, nitrogen, carbon and hydrogen. Mil. Z. Jovitch. *Glas* 142, 22 pp.(Separate); *Chem. Zentr.* 1932, I, 1194.—A report on the exptl. results on "transmutations" (cf. *C. A.* 26, 4230) which are observed as a result of the action of elec. rays on (1) hydrocarbons and their neutral derivs. (aldehydes, alcs., ketones, ethers), (2) H-contg. inorg. compds. ( $\text{H}_2\text{S}$ ,  $\text{AsH}_3$ , H halides), and (3)  $\text{S}_2\text{Cl}_2$ ,  $\text{PH}_3$ ,  $\text{PCl}_3$  and  $\text{SiCl}_4$  (in presence of  $\text{N}_2$ ). "In the first 2 groups pos. H is split off and the residue condenses with itself or with the H nucleus to form new mols. or new at. complexes." In group (3) the halogen probably splits off and the residue then combines with N or a product formed by the action of the elec. rays upon it.

#### 4—ELECTROCHEMISTRY

COLIN G. FINK

The basic electric furnace process. E. Mathieu. *Mem. compl. rend. soc. ing. civils France* 85, 1245-9 (1932).—An address.

A. Papineau-Couture

Operation and temperature control of electric furnaces by means of rectifiers. Buchting and H. Klemperer. *Siemens Z.* 13, 300-3(1933).—One of the advantages of the elec. furnace is a close temp. control which is usually effected by elec. regulating devices. Until recently these regulators operated on the principle of opening or closing contacts to provide, in stepwise succession, an increased or diminished power supply. A more uniform power supply can be obtained by using electron tubes as regulators. A resistance thermometer (Pt wire), photoelec. cell or bolometer, installed in the furnace, forms one arm of a Wheatstone bridge. The galvanometer arm is connected to the grid of an electron tube which controls the power input into the furnace. This principle is illus-

trated by various wiring diagrams, and the equipment is described which has been used in com. installations.

E. W. Volkmann

An electric furnace with demountable and interchangeable resistor elements. Maurice Billy and Felix Trombe. *Bull. soc. chim.* 53, 536-41(1933).—Nichrome windings are employed and it is possible to interchange elements during operation.

H. A. Smith

Current density in electrolytic baths. V. Alekseevskii. *J. Chem. Ind. (Moscow)* 1933, No. 6, 36-43.—Calculations are given to show the effect of design of electrodes on c. d.

H. M. Leicester

A laboratory study of asbestos diaphragms used in the electrolysis of aqueous solutions of sodium chloride. S. N. Lur'e, B. I. Rimmer and G. A. Volin. *J. Chem. Ind. (Moscow)* 1933, No. 6, 44-60.—Such diaphragms may be made from Russian materials. H. M. L.

The nature of the dropping-mercury electrode. E. Lange and M. Andager. *Physik. Z. Sowjetunion* 4, 262-5 (1933).—The improbable concn. values, calcd. for the sorption layer by the application of the Gibbs' equation to the observed potentials, leads to the proposal that no equil. exists, but that the velocity of ion transference is the potential-dtg. factor.

Determining the thickness of electrolytic deposits. Marcel Ballay. *Aciers Spéciaux* 8, 240-57 (1933).—The thickness of an electrodeposit can be detd. by means of micrographic examn. but more exactly by measuring the time it takes to dissolve the electrolytic deposit, and from this the thickness of the plate is detd. Many well-known solns. for dissolving each electrodeposited metal are given and discussed. Porosity, corrosion, hardness and brittleness tests are enumerated such as are in com. use in France.

Chromium-plating literature. XVIII. J. H. Decker. *Platers' Guide* 29, Oct. 13-14 (1933); cf. *C. A.* 27, 5649.

Testing chromium plate for resistance to abrasion. R. J. Pierson. *Metal Cleaning and Finishing* 5, 411-14 (1933).—An improved abrasion-testing machine is described.

Measurement of the throwing power of chromium-plating baths. A. Onitschenko. *Z. Elektrochem.* 39, 815-18 (1933).—A right-angled cathode is used, with one side perpendicular and the other parallel to the anode. Removable strips are held in a 3.5 mm. frame which takes the main portion of the current. The quant. effect of  $H_2SO_4$ , c. d., and temp. on the throwing power and current efficiency of Cr baths are investigated (cf. *C. A.* 23, 2664).

The limiting current in the anodic polarization of metals in aqueous solutions. III. Kurt Schwabe. *Z. Elektrochem.* 39, 791-9 (1933); cf. *C. A.* 27, 4739. Expts. show that Zn and Ag in satd. and unsatd. solns. of their chlorides, perchlorates and nitrates may not reach a limiting current with increasing anode potential. The current may increase to a max. limited by the danger of warming, or at const. potential may exhibit periodic fluctuations.

Nickel anodes. Erich Becker. *Metallborse* 22, 1293-4, 1325-6 (1932).—A review.

Chlorine in the lead storage battery. R. L. Shulley and O. W. Brown. *Proc. Indiana Acad. Sci.* 42, 123-6 (1933).—Chlorides in the acid electrolyte react with the  $PbO_2$  of the pos. plates, this resulting in the discharge of the plate and the evolution of  $Cl_2$ . The  $Cl_2$  bleaches the separators on the pos. plate side and shortens their life.  $Cl_2$  dissolves Sb from the pos. grid. During charge the  $Cl^-$  ions liberated on the pos. grid also dissolve Sb. This Sb is carried to the neg. plate where it is deposited as a sponge on the sponge Pb, thereby short-circuiting the plate. The pos. plate upon loss of Sb becomes peroxidized and very brittle. If the contaminated cell stands on open circuit, the  $Cl^-$  is eliminated, the rate depending upon the concn. of electrolyte and the concn. of  $Cl^-$  in the electrolyte. The elimination of  $Cl^-$  is increased by the charging and discharging of the cell.

Rectifiers for the charging of batteries in telephone exchanges. H. John. *Elek. Nach.-Tech.* 10, 386-8 (1933). Hg-vapor grid controlled rectifiers can advantageously be used for the d. c. supply of small telephone exchanges. An arrangement is described in which the rectifier is installed in a manner which permits the automatic supply of current for the recharging of batteries during those hours of the day when only part of the capacity of the rectifier is required for the operation of the telephones. At night the rectifier is shut off and the exchange operates on the energy of the batteries.

The minimum voltage of the electrolytic rectifier as a function of the variables involved. O. Mohr. *Z. Physik* 85, (679-82) (1933).—The min. potential which must be applied to a  $Ta$  or  $Al$  rectifier to obtain a perceptible current increases in proportion with the potential of film

formation. Other factors such as c. d., concn. and type of electrolyte, frequency, etc., are of little effect. E. B.

High-frequency electron tubes with grids as anode rectifiers. J. Kammerloher. *Elek. Nach.-Tech.* 10, 345-52 (1933).—Part of the paper consists of a detailed theoretical treatment of high-frequency electron tubes with grids used for anode rectification. Expts. are recorded the results of which show a good agreement with the theory.

A new rectifier composed of copper sulfide layers. Michel Anastassiades. *Compt. rend.* 197, (677-8) (1933).—A rectifier is made of layers of  $CuS$  and  $Cu_2S$ . The current travels from the  $CuS$  to the  $Cu_2S$ , and is insensible in the opposite direction.

The physical basis of discharges in rectifiers and their control by grids. Max Steenbeck. *Siemens Z.* 13, 251-60 (1933).—Without going into a math. treatment an account is given of all those phenomena which render electron tubes suitable for rectifying and control purposes. The discussion includes high-vacuum tubes with and without gas or vapor loading. Various diagrams and photographs illustrate the functioning of the grid.

New studies of the arc discharge. J. L. Myer. *Trans. Am. Inst. Elec. Engrs.* 1933 (preprint).—The equation  $V = A + B/I^n$  which represents correctly all normal arc characteristics is used as the starting point for a general discussion of arc phenomena and industrial applications. Tests of this equation are applied to Fe arcs in various gas atms. to obtain a series of values for  $A$  and  $B$  making possible certain deductions about arc-voltage variations and significance of the characteristics. In limiting the current exponent  $n$ , the anode temp. must exert considerable influence upon the discharge as a whole. Suggestions are given why this may be so. A value of  $n$  is predicted from the arc stream geometry, and is compared with actual values of  $n$  for various arcs.

Space charge vs. alternating-current corona loss about a conductor. Yoshio Satō. *J. Inst. Elec. Engrs. Japan* 53, 643-53 (1933).—The space charge about a conductor in 50- or 60-cycle corona was studied from the voltage charge cyclograms of a cathode-ray tube, and its effect on the corona loss was investigated. The results were compared with those calcd. from Peek's and Holm's formulas. For smaller conductors the measured and the computed losses coincide, while for larger conductors they do not agree. Addnl. factors which bring about a discrepancy between observed and calcd. values are discussed.

Osram sodium-vapor lamps. M. Reger. *A. E. G. Mit.* 1933, 196-8.—The demand for some artificial light source for the illumination of highways at night has resulted in the development of the Osram Na-vapor lamp. The theoretical disadvantage of the limited color range of Na-vapor light is of no practical importance as has been demonstrated by actual tests on highways. The Na highway lamp consumes 75 w., produces 3000 lumens and is built for operation on 220 v. a. c. It consists of 2 concentric glass tubes of which the inner one is the discharge tube. The outer tube serves for heat insulation. The annular space between inner and outer tube is evacuated. The light-emitting part of the tube is 22 cm. long. A current of 1.15 amps. and 60 v. maintains the discharge between the oxide electrodes. The difference between the voltage of the distributing system (220 v.) and the lamp (60 v.) is taken up by an inductance. In parallel with the main circuit 2 transformers are installed, the secondary windings of which (1.5 amp., 5 v.) are capable of heating the electrodes to discharge temp. When the discharge commences, the voltage across the electrodes decreases to 60 v. which, in turn, diminishes the heating current to such an extent that no further heating takes place. The lamp requires 5 min. to reach its efficient rate of light emission.

Electrodeposition on water service pipes and mains (Hill, et al.) 14. Production and deposition of  $Mn$  (Mur-

ray) 9. Resistor furnace (Ger. pat. 584,389) 19. Rendering fat from tissue (U. S. pat. 1,930,169) 27.

Engelhardt, Victor: Handbuch der technischen Elektrochemie. Bd. III. Elektrolyse im Schmelzfluss. Leipzig: Akad. Verlagsges. 560 pp. M. 52. Cf. C. A. 27, 5653.

**Batteries.** Georg Lüddecke and Graphitwerk Kropfmühl, A.-G. Brit. 395,456, July 20, 1933. Pos. electrodes of batteries are coated with a soln. of fully acetylated cellulose which may contain cellulose or other substances to increase the porosity when the coating is dry. Substances that may be dissolved out of the dried coating may be added to the soln. for the same purpose. In an example a Mn-graphite electrode is dipped in a soln. of cellulose acetate in  $\text{CHCl}_3$  (and alc.), the solvent being then evapd. off. In another example KCl is added to a soln. of the acetate in  $\text{Me}_2\text{CO}$  and alc. and the electrode, after being dipped therein, is dipped into  $\text{H}_2\text{O}$  to ppt. the acetate and dissolve out the KCl. Cf. C. A. 27, 3405.

**Rechargeable batteries.** George Rathbone and Arthur Wyers. Brit. 395,128, July 13, 1933. A battery comprises 2 cells in series, each having a pos. electrode of Cu and a neg. electrode which may be of Mg in a soln. of  $\text{CuSO}_4$ . A holder is provided for the neg. electrodes when the battery is not in use.

**Battery-paste extender.** James O. Johnstone (to Chemical & Pigment Co.). U. S. 1,929,357, Oct. 3. A battery-paste extender for a Pb-acid cell electrode is prepd. by mercerizing cellulose and forming a jelly-like material from it by soaking cellulose fiber material such as cotton or sawdust with a soln. of a Ba compd. such as  $\text{BaS}$  and then adding a soln. of a substance such as  $\text{Na}_2\text{SO}_4$  which reacts with the sol. Ba compd. to form an insol. Ba compd. and a water-sol. alk. compd. with consequent pptn. of the insol. Ba compd. in the mercerized fibers.

**Machine for bending pole strips of galvanic batteries.** Kasimir Baumgarten and Ferdinand Roessler. Brit. 395,598, July 20, 1933.

**Apparatus and method for making zinc covers for galvanic batteries.** Hans Bläsch. Brit. 396,261, Aug. 1, 1933.

**Accumulators.** Drumm Battery Co. Ltd. (formerly Ciba Ltd.) and James J. Drumm. Brit. 394,671, June 26, 1933. A storage battery in which Zn is plated out of an alk. electrolyte is provided with a neg. electrode of Ni, Co or monel metal or having a surface of 1 of these metals, e. g., Ni-plated Fe, the electrode being prepd. for reception of the Zn deposit by being heated in H at a high temp., e. g.,  $1040^\circ$ . Cf. C. A. 27, 5654.

**Accumulators.** Dunlop Rubber Co. Ltd. and Evelyn W. Mudge. Brit. 394,803, July 6, 1933. The plates of an accumulator are embedded in microporous rubber formed *in situ* in the cell and which may be provided with vents for the escape of gas. The rubber filling is obtained by pouring a sensitized latex mixt. over the plates until they are completely immersed and gelling by hot  $\text{H}_2\text{O}$ . Vulcanization is effected by hot  $\text{H}_2\text{O}$  and steam pressure.

**Accumulators.** Charles J. V. Fry. Brit. 395,376, July 13, 1933. To prevent H and O from reaching the pos. and neg. plates the container is divided by partitions into as many compartments as there are plates.

**Gas exit for accumulators.** Accumulatoren-Fabrik A.-G. (to Britannia Batteries Ltd.). Brit. 394,633, June 29, 1933.

**Continuous automatic electrodeposition apparatus.** Albert Jacob. Ger. 583,039, Aug. 28, 1933. Addn. to 578,475 (C. A. 27, 4178).

**Electrolytic condenser.** Joseph J. Barrett (to Magnavox Co.). U. S. 1,930,578, Oct. 17. In the wall of an electrolytic condenser, a small aperture is provided sealed with a metal of low m. p. such as soft solder for relieving any excessive pressure created within the condenser by volatilizing of the electrolyte.

**Electrolytic condensers.** The General Electric Co. Ltd. and Victor N. Halliday. Brit. 394,485, June 20,

1933. Two foils, of Al or other film-forming material, and an insulating sheet of cambric etc., are folded in a zig-zag manner, the sheets being impregnated with a substance, e. g., a soln. of Na borate that reacts with 1 or both foils to form an insulating film. The fabric layer may be replaced by a no. of raised spots of insulating material, e. g., varnish, applied to the surface of 1 or both foils.

**Electrolytic condensers.** Standard Telephones & Cables Ltd., George W. Clarke and Hugh S. Leman. Brit. 395,416, July 20, 1933. The electrodes are in the form of wires, insulated by porous material impregnated with electrolyte and closely wound together in bifilar fashion either as an open helix or round a former of insulating or magnetic material.

**Electrolytic system for coating wire with a poor conductor.** Radiohorenfabrik G. m. b. H. Ger. 582,251, Oct. 5, 1933.

**Electrolytic cell for production of metals such as magnesium from fused salts.** Alfred C. Jessup. U. S. 1,930,877, Oct. 17. Structural details.

**Electrolytic apparatus for regenerating potassium ferriocyanide used in desulfurizing gases.** Richard Brandt. Ger. 583,012, Aug. 26, 1933. Addn. to 503,118 (C. A. 24, 4994).

**Electrolytic reproduction of plate surfaces.** Howard B. Scott and Charles C. Conley (to National Cash Register Co.). U. S. 1,930,826, Oct. 17. For duplicating the surface of an intaglio grained master plate, to form a graining plate, the back of the master plate is coated with a plating resistant; a film of Ni is electroplated on the face of the master plate; the master plate is anodically treated in a caustic soln. and rinsed; a cortical layer of Ni is electroplated on the nickled face of the master plate; alternate and successive layers of superposed Cu and Ni are electroplated on the exposed side of the cortical layer to form a backing for it, and the cortical layer with its superposed backing layers is stripped as a unit from the master plate to form a "mother" or reverse master plate from which, by a described and generally similar procedure, a graining plate is formed to which a backing layer of Pb is applied by electroplating.

**Electrolytic production of metal sheet.** Anaconda Sales Co. Brit. 395,002, July 7, 1933. Metal is continuously deposited on a rotating cathode drum and is stripped as a foil. To build up the foil by further electrodeposition on 1 face only it is passed over a roller, down 1 face of a guide serving as cathode connection, up the other face and over a roller to successive rollers and guides, traveling in a series of vertical loops between sol. anode without ever passing beneath the anodes. App. is described.

**Apparatus for electrolytic reduction of aluminum.** Konrad Eigenheer (to Aluminium Industrie A.-G.). U. S. 1,930,195, Oct. 10. Various structural and operative details are described.

**Electrolytic surface treatment of aluminum and its alloys.** Charles H. R. Gower and Ernest Windsor-Bowen. Brit. 395,390, July 6, 1933. The metals are treated anodically in a bath contg. an Al salt as an initial component. A suitable electrolyte for a soft coating is obtained by mixing 160 l. dil.  $\text{H}_2\text{SO}_4$ , contg. 2.5 parts acid to 2 parts  $\text{H}_2\text{O}$ , with 20 l. of a 20%  $\text{Al}_2(\text{SO}_4)_3$  soln. a lower strength being used for a hard coating. The voltage may be 80-100 and the temp. 60-65° F. A small quantity, e. g., 1%, of a water-dispersible albumenoid colloid or a carbohydrate or polysaccharide, e. g., dextrin gum tragacanth, gum acacia, agar, etc., is added for soft coatings. Org. dyes or metallic salts imparting color to the coatings may be added or the coated articles subjected to solns. thereof.

**Magnetic electrolytic iron.** Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 395,505, July 20, 1933. Fe plates for magnetic purposes are deposited by electrolysis under such conditions as to contain C and N in approx. equiv. proportion so that on annealing in a vacuum both impurities are substantially completely removed.

**Beryllium-aluminum alloys.** Emil Baggli and Edwin Burger (Walter Pfau, inventor). Ger. 583,391, Aug. 26, 1933. See U. S. 1,919,379 (C. A. 27, 4744).

**Lead-calcium alloys.** Metallges. A.-G. (Wolhart Sieck, inventor). Ger. 584,399, Sept. 19, 1933. Alloys of Pb with up to 10% of Ca are prepd. by electrolyzing a fused halide of Ca with the use of a cathode of fused Pb to which sufficient addnl. heat is applied to maintain a cathode temp. above 630°, e. g., 650-700°. The cathode should be stirred during the process, e. g., by means of vertically reciprocated perforated disks. The electrolyte may contain more than one halide of Ca, with or without other metal halides, e. g., NaCl. Details are given.

**Electric heating apparatus.** Ole A. Lokke (to Aktieselskapet Elektrisk Bureau). U. S. 1,930,880, Oct. 17, 1933. Between a heat distributing body such as an iron plate and insulation which surrounds elec. resistance heaters such as chrome-Ni wire, a lining of Al is provided which serves to inhibit destruction of the heating wire. Mg, Cr or Mn also may be used.

**Electric crucible furnace suitable for use with salt baths for heat-treating metals.** Hermann Blomberg (to General Elec. Co.). U. S. 1,930,337, Oct. 10, 1933. Various structural and operative details are described.

**Electric muffle oven suitable for dental and general laboratory work.** Angelo D'Amico. U. S. 1,930,836, Oct. 17, 1933.

**Rotary electric annealing furnace.** Rudolf Gautschi. Ger. 584,378, Sept. 19, 1933.

**Tiltable electric annealing furnace.** Demag-Elektrostahl G. m. b. H. Ger. 584,377, Sept. 19, 1933.

**Carbon arc electrodes.** Wm. N. Wilson and The Morgan Crucible Co. Ltd. Brit. 395,073, July 13, 1933. C-rod arc electrodes, undecomposable by H<sub>2</sub>O, are impregnated in the surface stratum only with a H<sub>2</sub>O-resistant material, e. g., cellulose lacquer. The electrode may be coated with metal, e. g., Al, Cu, bronze, in addn. App. is described.

**Inductance coils.** Bertram S. Cohen, Frank O. Barralet and Ernest D. Hebdon. Brit. 394,327, June 15, 1933. The inductance of a coil is increased by spraying magnetic material onto 1 or more sides so as to provide it with a coating of finely divided particles sep'd. by insulating films. The particles may be coated with an insulating film by spraying the metal (Fe or Ni-Fe alloy) through (1) steam or H<sub>2</sub>O. Alternatively the magnetic material and an insulating material, e. g., a 10% soln. of a synthetic resin, may be sprayed simultaneously, or alternate layers of magnetic material and insulating medium may be sprayed to obtain a series of insulated metal films.

**Permeable diaphragms suitable for electroendosmosis.** Henry C. Howard and Ervin S. Kern (to American Anode, Inc.). U. S. 1,929,923, Oct. 10, 1933. Permeable diaphragms comprise undried unvulcanized coagulated rubber occupying the foramina of a foraminous support such as a woven wire screen.

**Electrical purification of gases.** Research Corporation of New York. Brit. 394,899, July 6, 1933. In the elec. pptn. of suspended particles from gases the gas is passed into a pptg. chamber through a no. of gas inlets arranged along its length. The distances between the inlets and (or) the amts. of gas introduced at the different points may be so adjusted that the concn. of suspended matter is substantially uniform throughout the region in which the gas is introduced. App. is described.

**Apparatus for electrical precipitation of suspended particles from gases.** Walther Deutsch (to International Precipitation Co.). U. S. 1,931,436, Oct. 17, 1933. Various structural and operative details are described.

**Preparing adsorptive material such as Barbourite for oil treatment, etc.** Justin F. Wait. U. S. 1,930,572, Oct. 17, 1933. Elec. current is passed between electrodes such as compressed Barbourite in a liquid such as a dispersing oil to form finely divided particles of the material having adsorptive properties, and these particles are purified by injection of H<sub>2</sub> to render them suitable for use in purifying addnl. oil. App. is described.

**Phosphorescent material.** Emil Rupp (to General

Elec. Co.). U. S. 1,930,110, Oct. 30, 1933. In the production of phosphorescent material consisting of a principal material such as NaCl or ZnS and a metallic addn. such as Mn or Cu, a body of the principal material which is a poor elec. conductor is interposed between 2 electrodes composed of the metal desired to be incorporated in the material; the electrodes and intervening material are heated to increase the elec. cond. of the principal material, and a current is passed which effects incorporation of some of the metal of the electrodes in the principal material.

**Apparatus for producing ozone.** Donald Simmons. Brit. 394,504, June 29, 1933.

**Dielectric materials.** Frank M. Clark (to The British Thomson-Houston Co. Ltd.). Brit. 394,776, July 6, 1933. In transformers, switches, condensers, etc., C<sub>6</sub>H<sub>5</sub>Cl<sub>2</sub> is used as the dielectric either alone or mixed with pentachlorobiphenyl, hexachlorobiphenyl or diphenyl oxide.

**Liquid dielectric for transformers, etc.** Frank M. Clark (to General Elec. Co.). U. S. 1,931,373, Oct. 17, 1933. Halogenated cyclic hydrocarbon compds. such as hexachlorobiphenyl and trichlorobenzene are used as dielectric material, and contain sufficient combined halogen in proportion to the H content that gases formed by decomposition of the material in use are substantially non-inflammable.

**Dielectric material suitable for use in transformers, switches, etc.** Frank M. Clark (to General Elec. Co.). U. S. 1,931,455, Oct. 17, 1933. Halogenated compds. of benzene and biphenyl such as trichlorobenzene and hexachlorobiphenyl are used together to provide a mixt. in which the halogen and H may be in substantially equimol. ratio and which is substantially non-inflammable.

**Arc-rupturing in switches.** Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 394,847, July 6, 1933. To increase the time of interruption of a vacuum switch and thereby reduce the inductive back e. m. f. a trace of rare gas or mixt. of rare gases is added to the chamber, the pressure in which is maintained below 0.1 mm. Hg.

**Dry rectifier.** Otto Irm (to Westinghouse Elec. & Mfg. Co.). U. S. 1,930,519, Oct. 17, 1933. In a dry rectifier consisting of a plurality of oxide-rectifier and contact rectifier units, each oxide-rectifier unit is connected in series with one contact-rectifier unit. Layers used may comprise Cu, Cu oxide, Pb, Mg and Cu sulfide.

**Mercury-vapor rectifiers.** Akt. Ges. Brown, Boveri & Cie. Brit. 395,383, July 6, 1933, and 395,400, July 17, 1933.

**Cathode for mercury-arc rectifier.** Errol B. Shand (to Westinghouse Elec. & Mfg. Co.). U. S. 1,929,656, Oct. 10, 1933.

**Rectifying tube with glow-discharge cathode.** György Szigeti (to Egy. sult. Izzolámpa és Villamosságai R. T.). U. S. 1,929,526, Oct. 10, 1933. For producing a rectifying glow-discharge cathode, a cathode base is coated with W bronze before the sealing-in of the support, and, after sealing in, the base in the tube is exposed to alk. earth metal vapor. Mo bronze also may be used.

**Discharge lamps.** Patent-Treuhand-Ges. für elektrische Glühlampen m. b. H. (to The General Electric Co. Ltd.). Brit. 394,861, July 6, 1933. A lamp with thermionic electrodes and a filling of a rare gas for starting in addn. to a metal vapor whose pressure during operation is less than the satn. pressure at the temp. of the discharge has a double-walled envelope, neither wall being of conductive material, and the electrodes are arranged in the inner space which is in communication with the outer space.

**Luminous discharge lamps.** N. V. Philips' Gloeilampenfabrieken. Brit. 395,224, July 13, 1933. Structural and elec. features.

**Flash bulbs.** Keishiro Kohayashi (to General Elec. Co.). U. S. 1,930,315, Oct. 10, 1933. Various structural details are described of flash bulbs contg. a highly inflammable filling such as Al or Mg foil in a combustion supporting gas such as O.

## 5—PHOTOGRAPHY

B. P. WIGHTMAN

Recent developments in infra-red photography. Olaf F. Bloch. *Chemistry and Industry*, 1933, 829-37.

E. H.

The topography of the latent x-ray image. Lüppo-Cramer and H. Steps. *Z. wiss. Phot.* 32, 113-28(1933).—From the results of expts. on a no. of German com. plates and films and on 2 emulsions which had not been after-ripened, with x-rays from a 52.5 kv., 7 ma., Siemens & Halske machine, L.-C. and S. conclude that the increase in sensitivity even to x-rays brought about by an exclusively nucleus-producing after-ripening, i. e., one without simultaneous grain-enlargement, and also the diminution in the x-ray sensitivity by desensitizing dyes and by  $\text{CrO}_3$ , prove that the sensitivity of a AgBr plate to x-rays is due in part to the ripening nuclei. These nuclei, moreover, cannot lie very far beneath the surface of the AgBr grain, since both they and the latent x-ray image are extensively destroyed by  $\text{CrO}_3$ . It has been found, in harmony with other results, that pure AgBr emulsions are more sensitive to the action of pure x-rays (i. e., the action when no intensifying screen is present) than the similarly produced AgI-contg. emulsions. For this there is no explanation other than that the grains are always appreciably larger in the former case. E. R. B.

Time lag in the formation of the latent (photographic) image. Lester I. Zimmerman. *J. Optical Soc. Am.* 23, 342-52(1933). See C. A. 27, 3887. G. G.

History of nitrocellulose as a film base. E. Theisen. *J. Soc. Motion Picture Engrs.* 20, 250-62(1933).

Color sensitivity of negative materials. A. Jack. *Phot. Chronik* 39, 11-15(1932).—A tabulation is given of the comparative color sensitivities of several negative materials, manufactured at the present time in Europe. The comparison was made with the Agfa color chart and the tricolor speed chart. G. W. Wilhelm, Jr.

Problem of red sensitizing with chlorophyll. G. Kogel. *Kinetisch* 14, 400-10(1932).—The conclusions of Stoll and Wiedemann (C. A. 27, 727) regarding the constitution of chlorophyll are briefly reviewed. K. believes that  $\beta$ -chlorophyll, which is present in the green leaves, might prove a better red sensitizer than the  $\alpha$ -chlorophyll hitherto tried. The  $\beta$ -chlorophyll is thought to be keto-diketone and to have an open ring in a certain position in which the  $\alpha$ -chlorophyll, a diketone, has a closed ring. M. W. Seymour

The real universal developer. Paul Kühne. *Phot. Rundschau* 69, 252-5(1932).—The following three-soln. developer is suggested: Soln. A.  $\text{H}_2\text{O}$ , 1 l.;  $\text{Na}_2\text{SO}_3$ , 7H<sub>2</sub>O, 140 g.; metol, 14 g. Soln. B.  $\text{H}_2\text{O}$ , 1 l.;  $\text{Na}_2\text{SO}_3$ , 7H<sub>2</sub>O, 100 g.; hydroquinone, 17 g. Soln. C.  $\text{H}_2\text{O}$ , 1 l.;  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ , 150 g. Times of development and diln. are tabulated for a large no. of plates, films and papers of several manufacturers. H. D. Russell

Fine-grain development with the A. B. C. universal developer. Paul Kühne. *Phot. Rundschau* 69, 315-16(1932).—The universal developer given in the preceding abstr. was used for a fine-grain developer after the addn. of borax and  $\text{Na}_2\text{SO}_3$ . H. D. Russell

Sceptical opinions on fine-grain developers. Lüppo-Cramer. *Phot. Rundschau* 69, 251-2(1932).—L.-C. believes that the modern fine-grain developers give no finer grain than ordinary developers if comparisons are made, as they should be, at equal gammas and equal densities for equal exposures. The finer grain obtained by using these solns. according to instructions results naturally from the lower gammas obtained. H. Parker, Jr.

The DIN scale: new German measure of photographic sensitivity. Martin Biltz. *Naturwissenschaften* 21, 734-6(1933).—The new DIN system of speed measurement is described and compared with former methods of photographic speed detn. with reference to the following: spectral distribution of light source employed; the type of d. curve obtained, i. e., intensity scale or time scale; and the manner of choosing an exposure value to designate

the speed. The new DIN method uses a daylight source obtained by means of a W lamp and a Davis-Gibson filter; an intensity-scale curve is obtained by means of a step wedge and guillotine shutter; and the speed is based on the energy/sq. cm. required to produce a density of 0.1 above fog. J. H. Webb

Influence of hydrogen-ion concentration on the light-sensitivity of gelatin-free silver bromide. A. I. Rabinovich and C. S. Bogdassaryan. *Z. wiss. Phot.* 32, 97-109(1933).—In continuing the previous investigation (C. A. 27, 673) and by using moist pptd. AgBr and measuring its light sensitivity by the amt. of Ag sepd. (dtd. volumetrically by a modification of the Kiesel method), it is found that the sensitivity increases with increasing  $p_{\text{H}}$ , the increase becoming more rapid above 7.5. The sensitivity increase is especially pronounced for exposures with red light. It is diminished, however, (as is also the general sensitivity of the AgBr) by the presence of an excess of Br ions. Results of potentiometric titrations indicate that this influence of the alky. in increasing light-sensitivity is to be attributed to adsorption of OH ions to the AgBr. E. R. Bullock

Schwarzschild effect for gelatin-free silver bromide. A. I. Rabinovich and C. S. Bogdassaryan. *Z. wiss. Phot.* 32, 110-12(1933).—In varying the intensity of the light source (a 5000-w. Philips Nitra lamp) by altering the distance, and varying the time of exposure between 5 and 540 min., R. and B. find, on the basis of the free Ag produced (cf. preceding abstr.), an av. value of 0.84 for the exponent  $p$  in the Schwarzschild equation as applied to the case of the direct darkening of moist, pptd. AgBr. They conclude that the reciprocity failure of com. emulsions is connected, in part at least, with the Ag halide grain itself. E. R. Bullock

Silver chromate. Lüppo-Cramer. *Z. wiss. Phot.* 32, 129-30(1933).—Prepd. with chloride-free gelatin and sol. chromate in slight excess, distd.  $\text{H}_2\text{O}$  being used throughout, a  $\text{Ag}_2\text{CrO}_4$  emulsion shows, with some yellow fog, a feeble panchromatic (predominantly yellow) sensitivity for phys. development. (On chem. development, an image appears but is quickly buried in fog.) Baths of KI (0.1%), KBr (10%), NaCl (10%) or even Na phosphate (10%) before phys. development act as nucleus denudants, strongly accelerating the development and increasing the ds. With 5%, as compared with 0.1%, KI, much fog and a reversed but more extensive image result. E. R. Bullock

Emulsion gelatin. Erwin Fuchs. *Phot. Ind.* 31, 558-9(1933).—The phys. and photographic properties of gelatins for emulsions are briefly discussed. The photographic properties are largely dependent upon the presence of traces of org. chemicals which promote speed and inhibit the fogging of the emulsion. C. E. Meulendyke

Statistical investigations on the grain of photographic emulsions. S. V. Cherdintzev. *Trans. Optical Inst. (Leningrad)* 9, 3-45(1933).—The size-frequency distributions of the AgBr grains in emulsions have been measured by the photographic process; special rules are used for the classification of sizes. A no. of com. emulsions of Russian and foreign production have been measured. It is found that each emulsion gives a definite frequency curve which can be expressed by 1 of 2 interpolation formulas, of which the following is the more convenient:  $f(x) = k/x \sqrt{\pi e^{-k^2(\ln x - a)^2}}$ , where  $k$  is a const. related to the dispersion,  $a$  is the log. of  $x_m$ , i. e., of the median of the distribution, and  $x$  is the size of grain. In large-grained emulsions the nos. of grains of small sizes do not fit this equation perfectly. It is observed that the crystals of Russian emulsions tend to differ from those of foreign emulsions in that the grains are more cubical in form and also that certain emulsions appear to consist of mech. mixts. of 2 original emulsions. C. E. K. Mees

Dependence of photographic properties of an emulsion

layer on the amount of silver per unit area. V. U. Michailov, R. V. Zouyca, and M. A. Gorochov. *Photochino Chem. Ind.* 3, 24-8 (1933).—As the thickness of coating is increased, the image d. increases until the amt. of emulsion is 7 cc. on a 9 by 12 cm. plate. Analysis shows the amt. of emulsion per plate varies considerably on plates of the same type, both in those prepd. in the Soviet factories and also on imported plates. The min. thickness of coating for  $\text{NH}_4$  emulsions is 4 cc. per plate to give a d. of not less than 2. The work is stated to be preliminary.

C. E. K. Mees

Preparation of a bromide emulsion for paper. A. I. Prilezhaev. *Trans. Optical Inst. (Leningrad)* 9, 46 9 (1933); cf. *C. A.* 27, 920.—The emulsion formula given differs from those already published in that a plain soln. of  $\text{AgNO}_3$  and afterward an ammoniacal soln. is added to the gelatin contg. KBr and citric acid. It is claimed that very large quantities of emulsion have been made by this formula and have proved satisfactory.

C. E. K. Mees

Regeneration of used fixing baths. A. A. Titov and T. N. Kreitzberg. *Photochino Chem. Ind.* 3, 53 7 (1933).—For the regeneration of fixing baths, "Rongalite," Na formaldehydesulfoxylate, is more satisfactory than  $\text{Na}_2\text{S}_2\text{O}_4$ . The reaction should be carried out in alk. soln. and after pptn. of the metallic Ag the fixing bath is suitable for use.

C. E. K. Mees

#### Photographic studies of detonation (Urbaniski) 24.

Color photography. I. G. Farbenind. A.-G. Brit. 395,124, July 13, 1933. Three-color photographic or cinematographic negatives are produced on a pack comprising a lenticular film superimposed on a smooth film, the lenticular film being nearer the objective, with which a 2-color selecting filter of the kind usual in lenticular-screen color photography is associated. The films are so sensitized and the filter colors so chosen that 2-component color-record images are produced on the lenticular film and the 3rd component on the smooth film, the latter being either in continuous tone or in broken tone.

Color photographs. Bela Gaspar. Brit. 395,718, July 17, 1933. Photographic dye images and cinematograph films are produced by treating a diffusely colored, photographic, metal-deposit image, free from metal halide, with an oxidizing agent which decolors the dye at the points free from metal. Ag and Hg images are mentioned. The oxidizing agent should not attack or color the photographic layer itself. Examples of baths for Ag images comprise (1) Ca hypochlorite,  $\text{AcOH}$  and  $\text{H}_2\text{O}$ , (2)  $\text{KBrO}_3$ ,  $\text{NaClO}_3$ ,  $\text{HCl}$  and  $\text{H}_2\text{O}$  and (3)  $\text{KBrO}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{CuSO}_4$  and  $\text{H}_2\text{O}$ . Hardening agents, e. g., alum, may be added to the baths. Simultaneously with the destruction of the dye the Ag image is converted into a salt, e. g., a chlorate or bromate; which dissolves out, or a halide, which may be removed in a dild. fixing-bath or may remain in the layer. Mixed tones may be obtained by using a mixt. of dyes which are destroyed with varying rapidity, e. g., a mixt. of Alizarine Blue and Diamine Fast-Pink G gives a violet color in the deep shadows and a rose color at the lighter points. Alternatively a dye may be used which changes color with oxidation. The effectiveness of the baths may be enhanced by adding catalytically acting salts, e. g., of V, U, Mo or Fe.

Light-sensitive substances. I. G. Farbenind. A.-G. Brit. 394,893, July 6, 1933. Light-sensitive products of unknown constitution are formed by reaction of an ester salt of a leuco-vat dye with a salt of a *N*-nitrosoaryl-hydroxylamine or a nuclear substitution product thereof. Such products may be produced in a layer of binding agent, e. g., gelatin, glue, collodion, already applied on a carrier or they may be formed *in situ* in or on a sheet of paper or cellulose hydrate. They may also be incorporated with the binding agent or in the paper, etc., sheets, e. g., by impregnation. Among examples (1) Na salt of leuco-4,4'-dichloro-5,5'-dibromoindigosulfuric acid ester (I) is converted to the pyridine salt by adding pyridine-HCl and then caused to react with the Na salt of nitrosophenylhydroxylamine; the product, after st

distn., is a  $\text{H}_2\text{O}$ -sol. powder which ppts. the vat dye on heating with dil. acids or on exposure to light; a layer sensitive to ultra-violet and giving a blue positive on printing under a negative is obtained by pouring an aq. soln. of this product, admixed with gelatin, onto a glass plate, etc., and (2) cellulose hydrate sheet is impregnated with an aq. soln. of I, the  $\text{NH}_4$  salt of *N*-nitrosoarylhydroxylamine and glycerol and dried.

Photographic sensitizers. I. G. Farbenind. A.-G. Brit. 396,217, Aug. 3, 1933. Ag halide emulsions, as sensitized to red by incorporating a carbocyanine dye derived from an azole base of formula  $\text{R.N:CMc.S}$ ,

where R is a residue of anthracene, phenanthrene, acenaphthene, fluorene, chrysene, carbazole or diphenylene oxide. The dyes are prepd. by treating a quaternary  $\text{NH}_4$  salt of a thiazole base of the above formula with a trialkyl orthocarboxylic acid ester. They are used as the bromide, iodide, perchlorate, etc., and may be added, e. g., in alc. soln., to the emulsion at any stage of its production or they may be incorporated by coating the cast, but not dried, emulsion layer. Among examples (1) 2-methyl- $\beta$ -anthranthiazole diethyl sulfate is heated in pyridine with triethyl orthopropionate at  $130^\circ$  and 1,1'-diethyl-*meso*-ethylantrathiocarbocyanine bromide pptd. by adding KBr, (2) 2-methylacenaphthenethiazole diethyl sulfate is heated in pyridine with triethyl orthoacetate and 1,1'-diethyl-*meso*-methylacenaphthenethiocarbocyanine bromide pptd. with KBr and (3) 1,1'-dimethyl-*meso*-methylidiphenylene oxide-thiocarbocyanine chloride is prepd. similarly from 2-methyldiphenylene oxide-thiazole dimethyl sulfate. Thiazole bases of the above formula are prepd. by converting an amino deriv. of anthracene, phenanthrene, etc., into the acetyl deriv. and the latter into the corresponding thioacetate compd. which is then oxidized by  $\text{K}_2\text{Fe}(\text{CN})_6$ . In an example acetyl- $\alpha$ -anthramine is treated with  $\text{P}_2\text{S}_5$  in xylene and the product oxidized by alk.  $\text{K}_2\text{Fe}(\text{CN})_6$  to 2-methyl- $\beta$ -anthranthiazole. Alternative methods given are (1) 9-benzyl-3-aminocarbazole is converted into 9-benzoyl-2-aminocarbazolethiazole by the process of Brit. 295,295 (*C. A.* 23, 2301) and this compd. sapon. according to Brit. 306,590 (*C. A.* 23, 5328). The *o*-mercaptamino-carbazole obtained is treated with glacial  $\text{AcOH}$  and  $\text{Ac}_2\text{O}$  to give the 2-methylthiazole compd. and (2) a similar series of operations applied to 2-aminodiphenylene oxide gives the corresponding 2-methylthiazole deriv. These bases are converted to their quaternary salts by known methods.

Sensitizing photographic emulsions. Leslie G. S. Brooker (to Kodak Ltd.). Brit. 394,601, June 30, 1933. Photographic emulsions, particularly Ag halide emulsions, are sensitized by a quaternary salt of a carbocyanine of the general formula  $\text{S.C}_6\text{H}_4\text{NRX:CCH.CACH.C.NH.C}_6\text{H}_4\text{S}$ ,

where A is an alkyl group contg. more than 1 C atom or a substituted alkyl group or (substituted) aryl group, R is an alkyl group and X an acid radical and in which the  $\text{C}_6\text{H}_4$  nuclei may contain 1 or more substituents. In 394,602, June 30, 1933, the dyes are prepd. by condensing a 1-methylbenzothiazole quaternary salt with a trialkyl ester of an orthocarboxylic acid, the acid corresponding to which is an aliphatic acid (contg. more than 2 C atoms), a substituted aliphatic carboxylic acid or (substituted) aromatic carboxylic acid. The  $\text{C}_6\text{H}_4$  nucleus may contain 1 or more substituents and suitable orthoesters are tri-Me orthopropionate, Me di-Et orthocaproate, Me di-Et orthoisocaproate, tri-Me orthovalerate, tri-Me  $\gamma$ -phenoxorthobutyrate, tri-Me phenylorthoacetate, tri-Me orthobenzoate and tri-Me ortho-p-toluate. Reaction may be carried out in boiling pyridine and the use of a 1-methylbenzothiazole quaternary salt contg. an acid radical such as *p*-toluenesulfonate is advantageous; the dye may then be isolated by double decompn. with  $\text{NHLiBr}$ , etc. Among dyes prepd. as examples by condensing the appropriate Me or Et 1-methylbenzothiazole-*p*-sulfonate with the appropriate ortho-ester and decomp. the product with al. alkali

bromide or iodide, are 2,2',8-triethylthiocarbocyanine iodide, 6,5'-dimethyl-2,8',8'-triethylthiocarbocyanine iodide, 2,2'-dimethyl-8-isoamylthiocarbocyanine iodide, 2,2',5,5'-tetramethyl-8-phenylthiocarbocyanine bromide and 2,2'-diethyl-8-p-tolylthiocarbocyanine iodide. The anion acid radical of the dyes may also be alkylsulfate, nitrate, acetate, perchlorate or other anion that does not adversely affect the soly. or sensitizing properties. The orthocarboxylic acid esters are prepd. by passing dry HCl into the acid nitrile, dissolved in a dry Et<sub>2</sub>O-alc. mixt., and causing the resulting imino-ether-HCl, after sepn. and drying, to react with mossy dry alc. Cf. C. A. 27, 2806.

**Photographic anti-halation layers.** I. G. Farbenind. A.-G. Brit. 395,889, July 27, 1933. A photographic film is furnished on its rear side with a thin, anti-halation, colloidal layer colored with non-actinic coloring matter, the layer being rendered detachable in the dry or wet state by pretreatment of the support or by choice of the solvent by which the layer is applied. A layer produced by means of an alk. casein soln., contg. CH<sub>2</sub>O and a coloring matter, is excluded. Suitable colloids comprise albumins, cellulose derivs. or natural or artificial resins. The treatment of the support, e. g., nitrocellulose or cellulose acetate, may consist in decreasing the gelatin content of the soln. of gelatin in glacial AcOH used prior to the application of the colloid layer; or the soln. may contain a solvent, e. g., alc., which exerts only a feeble swelling action. Alternatively, the layer is applied to the support without pretreatment, the solvent for the layer being such as to exert at most a feeble swelling action on the support. Examples are given of (1) a suspension of soot in aq. gelatin soln. applied to an untreated nitrocellulose or cellulose acetate support, (2) a similar suspension applied to a nitrocellulose film treated with a gelatin-AcOH-alc. soln., (3) a celluloid-graphite mixt. dissolved in an Et<sub>2</sub>O-alc. mixt. applied to an untreated cellulose acetate film and (4) a cellulose ether-soot mixt. dissolved in C<sub>2</sub>H<sub>6</sub> and applied to an untreated cellulose acetate film.

**Photographic plates.** Sillb. & Bruckmann und Gebr. Freundorfer G. m. b. H. Brit. 395,818, July 27, 1933. To prevent collodion plates<sup>6</sup> becoming horny when dry the plates, coated with a Ag halide collodion emulsion, are bathed with a soln. contg. a known softening agent, a dye of the quinoline group or ethyl violet and a sol. Ag salt of an inorg. acid, or with a soln. contg. a softening agent, a Ag salt of a dye of the phthalein group and, if desired, also a quinoline dye. If the plate has been previously dyed with a quinoline or phthalein dye it may be bathed with a soln. contg. a softening agent and an alk. Ag soln. In examples (1) a collodion Ag halide plate is bathed with a soln. contg. glycerol, the Ag salt of eosin and a large excess of alkali; (2) a collodion Ag halide plate, which may have been previously dyed with a quinoline dye, is bathed with a soln. contg. glycerol, a strongly alk. soln. of the Ag salt of eosin and an alc. soln. of a quinoline dye, e. g., pinacyanol, or of ethyl violet; and (3) a collodion Ag halide emulsion, dyed with fluorescein, erythrosin or eosin, or with a quinoline dye, or with 2 of these dyes, is treated with a strongly alk. soln. of AgNO<sub>3</sub>. A protective colloid, e. g., gelatin, albumin, albuminates or gums, may be added to the sensitizing soln. or to the Ag soln. to prevent clouding of the plate during drying. Sugar is also mentioned as a softening agent.

**Composite photographs.** Conrad G. Briels Brit. 395,492, July 20, 1933. A process of producing a composite picture embodying 2 or more different parts com-

prises producing an image of 1 component on a sensitive film, of a d. sufficient to exclude transmitted light during the 2nd exposure, exposing the film to the 2nd component, treating this image to produce a d. corresponding to that of the 1st image and treating the composite image so formed to make the image details visible by reflected or by transmitted light. Thus a film is first exposed to the foreground component and the image developed to opacity. An image is then made from the background component in the undeveloped AgBr and developed to opacity. A stop-bath may be used after either development. The composite image illuminated from the front may then be printed on a fresh sensitive surface. Alternatively, it may be treated with KMnO<sub>4</sub> and H<sub>2</sub>SO<sub>4</sub> or with CrO<sub>3</sub>, followed by an acid sulfite bath, to remove the Ag image and an opaque backing applied, the undeveloped AgBr forming an image which may be printed on a sensitive film. The undeveloped AgBr may also be developed and the image printed by transmitted light.

**Photographic film.** Oskar Schmidt (to General Elec. Co.). U. S. 1,929,290, Oct. 3. A transparent flexible film comprises a carrier consisting of a flexible condensation product of a polyhydric alc. such as glycerol and a "polybasic" acid such as phthalic anhydride on which the light-sensitive layer is placed.

**Non-halation photographic film.** Albert Narath (to General Elec. Co.). U. S. 1,929,254, Oct. 3. The rear face of the film is roughened and there is applied to it a light-absorbing substance such as carbon powder.

**Two photographic images of different contrasts on a single film with a single development.** John G. Capstaff (to Eastman Kodak Co.). U. S. 1,930,141, Oct. 10. A single sensitive Ag halide emulsion layer is exposed to one light image, the layer is then submitted to the action of an oxidizing agent such as a dil. chromic acid soln. and it is then exposed to a second light image, and both images are developed simultaneously.

**Combined sound and color picture films.** I. G. Farbenind. A.-G. Brit. 393,844, June 15, 1933. Sound is recorded photographically on a bi-pack in which 2 films are united with their light-sensitive emulsion layers adjacent to each other but sepd. by a filter layer dyed with a color complementary to a color to which 1 of the emulsions is sensitized. The film bearing the special color-sensitive layer is arranged nearer the objective, the sound being recorded on said film through its support. Erythrosin may be used for sensitizing the emulsion layer thereof to the yellow-green, a red filter layer of an alc. soln. of aurin being applied to the emulsion layer. A panchromatic emulsion is used for the 2nd layer.

**Electrical apparatus for embossing or goffering films for color photography, provided with thermostatic control** Keller-Dorian Colorfilm Corp. Brit. 395,200, July 13, 1933.

**Acid hardening photographic fixing bath.** Reinhold S. Becker (to Eastman Kodak Co.). U. S. 1,930,140, Oct. 10. An aq. soln. of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is used contg. also a sulfite, a hardening agent such as K alum, boric acid and a compd. such as HIOAc or NaOAc supplying acetate ions in a quantity over 1% (the concn. of the boric acid being at least half that of the acetate ions).

**Bromide recovery from spent photographic developers** Kenneth C. D. Hickman and Walter J. Weyerts (to Eastman Kodak Co.). U. S. 1,930,143, Oct. 10. Spent developers contg. bromides are electrolyzed with use of a Ag anode until substantially all the Br has been deposited on the anode.

## 6—INORGANIC CHEMISTRY

A. R. MIDDLETON

• Essential character of the Raman effect and its application to inorganic chemistry. Henri Volkringer. *Bull. soc. chim.* 53, 445-68 (1933).—A review of the exptl. and theoretical aspects of the application of the Raman effect, to inorg. chemistry. • Howard Agnew Smith

The characteristics of praseodymium. Bohuslav Brauner. *Collection Czechoslov. Chem. Communications* 5 279-86 (1933).—Pr<sub>2</sub>O<sub>3</sub> can be obtained pure as follows The mixed rare earth NH<sub>4</sub> nitrates, with 6 times their wt of a mixt. of NaNO<sub>3</sub> and KNO<sub>3</sub>, are fused at 350° for some

time. All the Fe and Ce sepd. as  $\text{Fe}_2\text{O}_3$  and  $\text{CeO}_2$ . The ppt. is washed with concd.  $\text{NH}_4\text{NO}_3$  soln. and the filtrate evapd. to dryness. The residue is fused at  $415^\circ$  when  $\text{Pr}_2\text{O}_3$  seps. as a black mass which is free from La. The at. wt. of Pr is 140.94. Green  $\text{Pr}_2\text{O}_3$  forms salts with acids.  $\text{Pr}_2\text{O}_3$  evolves  $\text{O}_2$  with acids to form trivalent salts; therefore it is not a true peroxide and Pr must be quadrivalent. An oxide,  $\text{Pr}_2\text{O}_{18}$ , was shown to be a salt of the other two oxides. John B. Milbury

**Bivalent rhodium.** Hans Reihlen and Werner Huhn. *Z. anorg. allgem. Chem.* 214, 189-95 (1933).—If a soln. of  $\text{RhCl}_3$  and  $\text{Na}_2\text{SO}_3$  is heated on a water bath 0.5-10 hrs.  $\text{Na}_2[\text{Rh}(\text{SO}_3)_2] + x \text{Na}_2\text{SO}_3$  seps. as a yellow ppt. It is insol. in  $\text{H}_2\text{O}$  and org. solvents; it is sol. in dil.  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{C}_2\text{O}_4$ ; it is not reduced by  $\text{N}_2\text{H}_4$  nor oxidized by cold  $\text{I}_2$ . B. A. Soule

**Revision of the atomic weight of tellurium. II. Synthesis of silver telluride.** O. Hönigschmid. *Z. anorg. allgem. Chem.* 214, 281-8 (1933).  $\text{Ag}_2\text{Te}$  was prepd. by heating a weighed quantity of Ag in Te vapor. From the relationship  $\text{Ag}_2\text{Te} \cdot 2\text{Ag} = 1.591416$ , the at. wt. of Te is 127.61. H. Stoertz

**Recent investigations on borates and boron.** L. Hackspill. *Helv. Chim. Acta* 16, 1099-118 (1933).—A review of recent work on (1) borates: their formulas, nomenclature, prepn. and hydrates; (2)  $\text{BCl}_3$  and its systems with  $\text{Cl}_2$ ,  $\text{HCl}$  and  $\text{AsH}_3$ ; (3) B: its prepn. and properties. B of high purity was prepd. by passing a high-frequency arc through a mixt. of  $\text{BCl}_3$  and  $\text{H}_2$  with W electrodes. J. H. Reedy

**The second monoclinic and the rhombohedral modification of sulfur.** O. v. Deimes. *Z. anorg. allgem. Chem.* 214, 330-4 (1933).—One can no longer assume that the monoclinic S obtained from solns. is other than the familiar  $S_8$  obtained from molten S, even if the crystal angles of the crystals obtained from soln. have not been measured. The unique characteristic of this S is the transformation into  $S_8$ . H. Stoertz

**Iodine in aqueous ammoniacal solution.** Eugen Churnoaga and Eugenia Churnoaga. *Z. anorg. allgem. Chem.* 214, 167-76 (1933).  $\text{I}_2$  is vigorously shaken with hot aq.  $\text{NH}_3$ ,  $\text{N}_2$  is evolved and a soln. obtained contg.  $\text{I}_2 + \text{NH}_4\text{I}$ , also traces of  $\text{NH}_4\text{IO}_3$ . The data for one sample, in g./100 cc. of soln., are:  $\text{NH}_3$ , 2.0;  $\text{I}_2$ , 9.24;  $\text{IO}_3^-$ , 0.05;  $\text{I}^-$ , 8.66. The  $\text{I}_2$  is colloidal but cannot be removed by dialysis through a collodion membrane. B. A. Soule

**Pseudohalogens. XXII. The reactions of metallic salts with iodine and bromine in the presence of benzene.** Lothar Bickenbach and Josef Goubeau. *Ber.* 66B, 1280-7 (1933); cf. C. A. 27, 66.— $\text{AgClO}_4$ ,  $\text{AgNO}_3$ ,  $\text{AgNO}_2$ ,  $\text{AgIPO}_4$ ,  $\text{AgOAc}$  and  $\text{AgIPO}_4$  with  $\text{I}_2$  and  $\text{C}_6\text{H}_6$  gave  $\text{C}_6\text{H}_5\text{I}$  in varying yields.  $\text{AgCl}$  gave no reaction. Similarly  $\text{Hg}^{++}$  and  $\text{Au}^+$  salts reacted;  $\text{Cu}^+$  and  $\text{Cu}^{++}$  reacted slightly and  $\text{Zn}^{++}$ ,  $\text{Cd}^{++}$ ,  $\text{Tl}^+$  and  $\text{Pb}^{++}$  gave no reaction.  $\text{AlCl}_3$ , known to hasten such reactions, speeded up those shown to occur but gave no reaction in the other cases.  $\text{Br}_2$  similarly failed to give reaction of the inactive group.  $\text{CaO}$ ,  $\text{Na}_2\text{CO}_3$  and  $\text{NaClO}_4$  do not cause reaction. The reaction is associated with non-polar compds.; intermediate types show partial reaction. Removal of acid formed, by  $\text{CaO}$  or  $\text{Na}_2\text{CO}_3$ , does not cause reaction, indicating that it is not a very slow reaction in that case. Various side reactions which occur are described. Foster Dee Snell

**Hydrazinate of silver halide.** H. Gall and H. Roth. *Z. anorg. allgem. Chem.* 214, 201-8 (1933).—In continuation of previous expts. (cf. C. A. 26, 5509), the prepn. of  $\text{N}_2\text{H}_3\text{AgCl}$ ,  $\text{N}_2\text{H}_3\text{AgBr}$ ,  $\text{N}_2\text{H}_3\text{AgI}$ ,  $\text{AgClC}_6\text{H}_5\text{NHNH}_2$ ,  $\text{AgBrC}_6\text{H}_5\text{NHNH}_2$  is described. M. McMahon

**Reducibility of beryllium chloride with metallic aluminum.** Walter Kangro. *Metall u. Erz* 30, 389-90 (1933).— $\text{BeCl}_2$  can be reduced to Be by Al, even at temps. low enough (200-300°) to prevent volatilization of the costly  $\text{BeCl}_2$ . Hellmut Fischer and Newton Peters. *Ibid.* 390-1. — $\text{BeCl}_2$  was reduced with Al in an atm. of  $\text{H}_2$ . At 260°, 12-17% reduction had occurred in 30 min. and at 350°, 30-40%. Special precautions must be taken to prevent

oxidation, such as weighing and mixing the  $\text{BeCl}_2$  and Al in  $\text{CO}_2$ . H. Stoertz

**Preparation of germanium tetrachloride from germanite.** F. Stienstra. *Chem. Weekblad* 30, 706-9 (1933).— $\text{GeCl}_4$  can be prepd. from germanite by treating the mineral with a  $\text{HNO}_3$ - $\text{H}_2\text{SO}_4$  mixt. The  $\text{GeO}_2$  formed is dissolved in  $\text{HCl}$  and the  $\text{GeCl}_4$  distd. in a Cl current. From 10 kg. germanite 1340 g.  $\text{GeCl}_4$  was obtained. E. Schutte

**Some reactions of rhenium chloride.** W. Geilmann and Fr. W. Wrigge. *Z. anorg. allgem. Chem.* 214, 248-60 (1933).—The hydrolysis of  $\text{ReCl}_5$  in  $\text{H}_2\text{O}$  can be followed with cond. measurements. There is complete change of  $\text{ReCl}_5$  into  $\text{Re}_2\text{O}_7 \cdot \text{H}_2\text{O}$  and  $\text{HCl}$ .  $\text{ReCl}_5$  is reduced to the metal by  $\text{H}_2$  without the formation of lower chlorides. On heating  $\text{ReCl}_5$  with  $\text{O}_2$ ,  $\text{ReOCl}_4$  and  $\text{ReO}_2\text{Cl}$  are formed. In acid,  $\text{H}_2\text{O}$ -sol.  $\text{ReCl}_5$  is stable toward  $\text{O}_2$ .  $\text{ReCl}_5$  decomposes on heating in dry  $\text{N}_2$  into  $\text{ReCl}_4$  and  $\text{Cl}_2$ ; in  $\text{O}_2$ ,  $\text{ReOCl}_4$  and  $\text{ReO}_2\text{Cl}$  are formed.  $\text{ReCl}_5$  reacts with alkali with the formation of  $\text{ReO}_2 \cdot \text{H}_2\text{O}$  and perchlenate; with acids mixts. of  $\text{HReO}_4$ ,  $\text{H}_2\text{ReCl}_6$  and free Cl appear. In the thermal decompn. of  $\text{Ag}_2\text{ReCl}_6$  equal mol. amts. of  $\text{ReCl}_4$  and  $\text{ReCl}_5$  are formed;  $\text{ReCl}_4$  cannot be isolated. M. McMahon

**Rhenium trichloride.** Wilhelm Geilmann, Friedr. W. Wrigge and Wilhelm Biltz. *Nachr. Ges. Wiss. Göttingen, Math.-physik. Klasse No. 5*, 579-87 (1932).—Chlorination of Re produces a mixt. of  $\text{ReCl}_3$  and  $\text{ReCl}_4$  from which the former can be obtained in pure state by sublimation at  $450^\circ$ . In aq. soln.  $\text{ReCl}_3$  is only slightly ionized. Hydrolysis takes place slowly with the formation of a black hydrated oxide, possibly  $\text{Re}_2\text{O}_7$ . Insol. double salts are formed with  $\text{RbCl}$  and  $\text{CsCl}$ . In liquid and aq.  $\text{NH}_3$  a violet ammoniate is formed. The salt is oxidized slowly by strong oxidizing agents; with  $\text{H}_2\text{S}$ ,  $\text{Re}_2\text{S}_7$  is formed, Zn in acid soln. removes part of the Cl. When strongly heated, especially in the presence of KCl, decompn. into metallic Re and  $\text{ReCl}_4$ , or  $\text{K}_2\text{ReCl}_6$ , takes place. H. P. Johnstone

**Rhenium trioxide and rhenium dioxide.** Wilhelm Biltz. *Z. anorg. allgem. Chem.* 214, 225-38 (1933).—Supplementary data (cf. C. A. 26, 5025, 5238) are presented on the prepn., crystal structure, elec. cond. and magnetic behavior of  $\text{ReO}_3$  and  $\text{ReO}_2$  and on the density and thermal decompn. of  $\text{ReO}_3$ . The action of alkali fusions on  $\text{ReO}_3$  and  $\text{ReO}_2$  and of  $\text{NaOH}$  soln. on  $\text{ReO}_3$  is reported with tabulated results. The existing oxides and chlorides of Re and Mn are compared. M. McM.

**Rhenium sesquioxide  $\text{Re}_2\text{O}_5$ .** W. Geilmann and Fr. W. Wrigge. *Z. anorg. allgem. Chem.* 214, 239-43 (1933).—The prepn. of a somewhat pure  $\text{Re}_2\text{O}_5$  from  $\text{ReCl}_5$  can only be accomplished with the greatest possible exclusion of air because of its ready oxidation to perchlenate. Thus far it has been impossible to obtain pure, dry  $\text{Re}_2\text{O}_5$ . M. McMahon

**Rhenium pentachloride.** Wilhelm Geilmann, Friedr. W. Wrigge and Wilhelm Biltz. *Z. anorg. allgem. Chem.* 214, 241-7 (1933).—Contrary to previous literature,  $\text{ReCl}_5$  and not  $\text{ReCl}_4$  can be obtained in the pure state.  $\text{ReCl}_5$  obtained by heating Re metal in a stream of Cl is brownish black; its vapors are dark brown; at atm. pressure it cannot be volatilized undecomposed; even on melting some decompn. occurs. M. McMahon

**Action of selenium dioxide and of selenium oxychloride on methon.** Hellmuth Stamm and Kurt Gossraß. *Ber.* 66B, 1658-63 (1933).—By addn. of  $\text{SeO}_2$  to methon (1,1-dimethylhydrosorcinol) in  $\text{MeOH}$ , anhydro-dimethon-selenium oxide (I) is produced, m.  $167^\circ$ . Addn.

of  $\text{Br}_2$  to I in  $\text{MeOH}$  gives 4,4-dibromomethon.  $\text{H}_2\text{Se}$  and  $\text{H}_2$  reduce I, probably to anhydro-dimethon-selenite; air again oxidizes it to I.  $\text{N}_2\text{O}_5$  oxidizes a  $\text{CHCl}_3$  soln.

of I to anhydro-dimethonselenon (II),

$$\begin{array}{c} -\text{C}-\text{SeO}_2-\text{C}- \\ | \quad | \\ \text{C}=\text{O} \quad \text{O}=\text{C} \end{array}$$

decompn. pt.  $150^{\circ}$ .  $\text{SO}_2$  reduces II to I.  $\text{SeOCl}_2$  reacts with methon in  $\text{CCl}_4$  to give 4-chloromethon monohydrate. It is suggested that the completeness of the reaction of methon with  $\text{SeO}_2$  offers promise as a quant. method of estn. of  $\text{H}_2\text{SeO}_3$  and its salts. F. D. S.

**Iodine pentoxide and its hydrates.** II. E. Moles and A. Parts. *Anales soc. españ. fis. quim.* 31, 618-22(1933); cf. C. A. 26, 5821.—If I is oxidized by fuming  $\text{HNO}_3$ , the product evapd. to dryness and recrystd. from 50-60%  $\text{HNO}_3$  soln., well-formed, tabular, shining crystals of  $3\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ , but no  $\text{HIO}_3$ , are obtained.  $3\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ , on dehydration, acts quite differently from the anhyd. product obtained by breaking down ordinary  $\text{HIO}_3$ . Dehydration to  $\text{I}_2\text{O}_5$  is not quant., since there is always decomn. The  $d_{20}^{20}$  of  $\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$  is 5.074 so that the mol. vol. of  $\text{H}_2\text{O}$  of ordinary  $\text{HIO}_3$  is 13, a value fairly well in accord with other investigations. E. M. Symmes

**Chlorine hexoxide and chlorine trioxide.** C. F. Goodeve and F. A. Todd. *Nature* 132, 514-15(1933).—Mol. wt. detns. of Cl hexoxide have previously been made only in soln. and correspond to the formula  $\text{Cl}_2\text{O}_6$ . Expt. shows that in the gaseous state the compd. exists entirely as  $\text{ClO}_3$ . It is assumed to be assocd. in the liquid phase as  $\text{Cl}_2\text{O}_6$ . Calvin Brous

**Active oxides. LVI. Absorbing power of zinc oxalate, partially decomposed by heat, toward methanol vapor.** Gustave Hüttig and Alexandre Meller. *Chimie & industrie Special No.*, 788-92(June, 1933); cf. C. A. 27, 1560.—The MeOH-adsorption isotherms were detd. for  $\text{ZnC}_2\text{O}_4$  and the residue remaining after heating the salt at  $405^{\circ}$  for 14-240 min. exhibits marked adsorptive power, which increases as the degree of decomn. increases, reaching a max. for a mol. ratio of 1 ZnO to 0.105  $\text{C}_2\text{O}_4$ . The adsorptive power of pure ZnO obtained by heating  $\text{ZnC}_2\text{O}_4$  at  $405^{\circ}$  for 7 hrs. is practically the same as that of the original  $\text{ZnC}_2\text{O}_4$ ; that of calcined ZnO is almost nil. Complete bibliography of II. and coworkers' investigations on active oxides. A. Papineau-Couture

**The combination of calcium in the system: lime-titanium dioxide and in lime-silicon dioxide-titanium dioxide.** Isidro Parga-Pondal and Karl Bergt. *Anales soc. españ. fis. quim.* 31, 623-37(1933).—In the system  $\text{CaO-TiO}_2$ , if CaO is present in sufficient quantity or in excess,  $\text{CaO-TiO}_2$  forms up to  $1300^{\circ}$ , but at  $1400^{\circ}$   $3\text{CaO} \cdot \text{TiO}_2$  is formed. Melting corresponding raw mixts. in the oxyacetylene flame indicates the existence of titanates rich in CaO. In the system  $\text{CaO-SiO}_2\text{-TiO}_2$ , with gradual substitution of  $\text{SiO}_2$  by  $\text{TiO}_2$  the CaO combination at first rises, then falls. At low temps. and low  $\text{TiO}_2$  contents the CaO combination is facilitated. There is no evidence of formation of double compds. between Ca silicates and Ca titanates. E. M. Symmes

**Calcium aluminate. III. The crystallization of calcium aluminate solutions at  $90^{\circ}$ .** Gunnar Assarsson. *Z. anorg. allgem. Chem.* 214, 158-66(1933); cf. C. A. 26, 4004.—The products obtained were identical in compn. with those isolated at  $40^{\circ}$ . B. A. Soule

**Chemical constitution of hydrated calcium aluminates.** Paul Erculisse and S. Sapgir. *Chimie & industrie Special No.*, 806-19(June, 1933).—The theory of thermodynamic methods of investigating the chem. constitution of hydrated Ca aluminates is explained. From preliminary expts., which are described in detail, the existence of a compd. or of a solid soln. of the compn.  $\text{Al}_2\text{O}_3 \cdot 4\text{CaO}$  seems probable, but not that of  $\text{Al}_2\text{O}_3 \cdot 2\text{CaO}$ . The existence of  $\text{CaAl}_2\text{O}_6 \cdot \text{aq.}$  is indicated. A. Papineau-Couture

**Change of constitution of tricalcium orthophosphate after fusion.** A. Travers and Baucr. *Helv. Chim. Acta* 16, 918-22(1933).—See C. A. 27, 4186. G. G.

**The double nitrate of copper and ammonium.** Jaroslav Milbauer and Josef Doškač. *Chimie & industrie Special No.*, 787(June, 1933).—The product obtained by mixing solns. of  $\text{Cu}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and  $\text{NH}_4\text{NO}_3$  is not a true double salt, but is merely  $\text{NH}_4\text{NO}_3$  contg.  $\text{Cu}(\text{NO}_3)_2$  occluded or entrained in the course of crystn. A. P.-C.

**Oxidation of thalious salts to thallic and reduction of the thallic salts with sodium arsenite.** F. Čuta. *Collection Czechoslov. Chem. Communications* 5, 287-301

(1933); cf. C. A. 17, 2684.—The purpose of this work was to find the conditions under which the reaction,  $\text{Ti}^{+++} + \text{AsO}_3^{--} + \text{H}_2\text{O} \rightarrow \text{Ti}^{IV} + \text{AsO}_4^{--} + 2\text{H}^+$ , is quant.  $\text{Ti}_2\text{CO}_3$ , recrystd. until shown pure by titrating with acid, was used as a standard. It was oxidized with aq.  $\text{Br}_2$  in  $\text{HCl}$  soln. and the excess  $\text{Br}_2$  expelled on a water bath. The use of other acids in the oxidation, without a sol. chloride, gave low results, because of the partial reduction of the  $\text{Ti}^{+++}$  while heating to expel the  $\text{Br}_2$ . The addn. of a sol. chloride to these solns. prevents reduction by the formation of  $\text{TiCl}_4$ . After the  $\text{Br}_2$  was expelled, an excess of  $\text{Na}_2\text{AsO}_3$  was added, the soln. warmed for  $\frac{1}{2}$  hr. and back titrated with  $\text{I}_2$ . The reduction was carried out in acid,  $\text{NaHCO}_3$ , and basic solns. with equally good results. The mean error for the detn. of Ti by this method was about 0.2%. J. E. M.

**Lead compounds of glycocoll, cysteine and thiohydra- acrylic acid.** R. Kliment. *Ber.* 66B, 1312-15(1933).—

0.25 g. of freshly pptd.  $\text{Pb}(\text{OH})_2$  to 0.25 g. of cysteine and 0.35 g.  $\text{Na}_2\text{CO}_3$  in 20 cc.  $\text{H}_2\text{O}$ , or by treating cysteine-sodium with  $\text{Pb}(\text{OH})_2$ , is identical in properties and compn. with the substance described by Bauer and Burschkes (C. A. 27, 5059). By the action of thiohydraacrylic acid either with  $\text{Pb}(\text{OAc})_2$  or with  $\text{Na}_2\text{CO}_3$  and freshly pptd.  $\text{Pb}(\text{OH})_2$ , a lead salt,  $\text{Pb}(\text{SCH}_2\text{CH}_2\text{CO}_2)\text{Pb}(\text{I})$ , is obtained. I, heated with 20 cc. of 2 N  $\text{Na}_2\text{CO}_3$ , gave  $\text{PbCO}_3$  and  $\text{SCH}_2\text{CH}_2\text{CO}_2\text{Pb}$ . Louise Kelley

**Manganous sulfates.** F. Hammel. *Compt. rend.* 197, 684-6(1933).— $\text{MnSO}_4 \cdot 5\text{H}_2\text{O}$  on exposure to air attains the compn.  $\text{MnSO}_4 \cdot 1.37\text{H}_2\text{O}$ ; when crystd. at the b. p. and dried at  $135^{\circ}$  it gives  $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ ; when dried *in vacuo* at  $100^{\circ}$  it gives  $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ ; at  $400^{\circ}$  it gives  $\text{MnSO}_4$  in 40 hrs. at  $150^{\circ}$  *in vacuo* it gives  $\text{MnSO}_4 \cdot 0.8\text{H}_2\text{O}$ . The f.-p. depressions of solns. of  $\text{MnSO}_4$  were independent of the method of dehydration. This disagrees with the conclusions of de Forcrand (C. A. 8, 3162, 3276) and Krepelka and Rejha (C. A. 26, 1536). G. M. P.

**The action of alkali carbonates on lime water and on solutions of calcium salts; also the lime of Loiseau.** O. Spengler and G. Dorfmueller. *Z. Ver. deut. Zuckerind.* 83, 562-81(1933).—To study the mechanism of the formation of hydrated  $\text{CaCO}_3$ , as well as of hydrate double salts of  $\text{CaCO}_3$  and alkali carbonates, the author examd. the action of  $\text{Na}_2\text{CO}_3$  on (1) lime water, (2) soln. of Ca acetate, at varying concns., and temps. I: all cases a primary floccular substance (hydrated  $\text{CaCO}_3$ ) which causes gelling, is first formed. This substance is then transformed, and that the more rapidly as the temp. decreases and as the concn. of  $\text{Na}_2\text{CO}_3$  increases, into cryst.  $\text{CaCO}_3 \cdot 6\text{H}_2\text{O}$ , or into a double carbonate, e. g.  $\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$ . In other cases it is transformed into aragonite or calcite. The various stages of the changes were studied microscopically. The primary substance is a hydrated  $\text{CaCO}_3$ ; it is possible that the hydrated salts of Ca can likewise produce the gelification of sufficiently concd. solns. Ca salts of glycolic and oxalic acids would show similar behavior. F. C.-C.

**Synthesis of metallic hydrides by the use of atomic hydrogen.** Erich Pietsch, F. Seufferling, W. Roman and H. Lehl. *Z. Elektrochem.* 39, 577-85(1933).—When Be treated with at. H at  $170-260^{\circ}$  for 7 hrs. a salt-like hydride formed which is completely sol. in water with gas evolution and gives a test for Be ion with 1,2,5,8-tetrahydroxyanthraquinone. When Ga is treated with at. H at  $100-170^{\circ}$  for 15 hrs. a salt-like hydride is formed which reacts with water with heat evolution and momentaril colors red litmus paper blue. The soln. gives a test for Ga ions. It likewise forms a yellowish gray salt-like hydride with at. H. Ta forms a salt-like hydride at  $150^{\circ}$  with at. H which reacts with water to form Ta ion in soln. W forms no hydride with at. H under the conditions tried. Pure hydrides suitable for analysis were not

obtained. Earlier work on the prepn. of the hydrides of Ag, Tl, Pb, Cu and Au (C. A. 26, 1535, 1536) is reviewed.

Oden E. Sheppard

Direct combination of hydrogen with phosphorus. R. Deliqué. *Bull. soc. chim.* 53, 603-12 (1933).—An attempt to verify the results of Retgers (Z. anorg. Chem. 7, 265 (1894)) was made without success. Red P heated in a reaction tube at 400° in a stream of H does not give either the gaseous, liquid, or the solid H phosphides. Between 400° and 550° PH<sub>3</sub> may be found in small quantities. The velocity of vaporization of P in H<sub>2</sub> and in N<sub>2</sub> is the same.

Howard Agnew Smith

The effect of nitric acid on hypophosphoric acid. Bruno Blaser. *Z. physik. Chem.* A166, 59-63 (1933).—HNO<sub>3</sub> does not oxidize H<sub>4</sub>P<sub>2</sub>O<sub>6</sub> but catalyzes the hydrolysis to H<sub>3</sub>PO<sub>3</sub> and H<sub>2</sub>P<sub>2</sub>O<sub>4</sub>. In the presence of both HCl and HNO<sub>3</sub> the hydrolysis is unimol. The rate of hydrolysis gives a measure of the acid strength in concd. soln.

G. M. Murphy

The two forms of phosphorous acid. Roger Deliqué and André Grangiers. *Compt. rend.* 197, 618-20 (1933).—The surface tension of solns. of PCl<sub>3</sub> at 20° was detd. by Dubray's method (cf. C. A. 12, 1355). It increases with time and concn. for solns. contg. 20, 10 and 2% PCl<sub>3</sub> and decreases for 1.5 and 1% solns., all tending to a limiting value. These facts agree with the existence of 2 forms of H<sub>3</sub>PO<sub>3</sub> in equil. The  $\rho_{\text{H}}$  of the 1% soln. decreases with time while for higher concns. it increases. The dil. solns. must contain at first more and the higher concns. less of the 3 OH form.

Janet E. Austin

Metaphosphoric acid. A. Travers and Chu. *Helv. chim. Acta* 16, 913-17 (1933).—Mixts. of H<sub>3</sub>PO<sub>4</sub>, H<sub>4</sub>P<sub>2</sub>O<sub>7</sub> and HPO<sub>3</sub> may be analyzed (1) by pptg. with Zn<sup>++</sup> in solns. of regulated acidity and NH<sub>4</sub>Cl concn., and (2) by titration with NaOH with methyl orange and phenolphthalein as indicators. In this way it is shown that the HPO<sub>3</sub> formed either by the action of P<sub>2</sub>O<sub>5</sub> on water or by igniting (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> is hydrated directly to H<sub>3</sub>PO<sub>4</sub>, without forming any H<sub>4</sub>P<sub>2</sub>O<sub>7</sub>. Com. glacial phosphoric acid

is a mixt. of H<sub>3</sub>PO<sub>4</sub> and NaPO<sub>3</sub> (about 61.2%).

J. H. Reedy

Preparation and properties of the permolybdates Na<sub>2</sub>MoO<sub>4</sub> and Na<sub>2</sub>MoO<sub>3</sub>. N. I. Kobozov and N. N. Sokolov. *Z. anorg. allgem. Chem.* 214, 321-9 (1933); C. A. 27, 5026.—Na<sub>2</sub>MoO<sub>3</sub> is prepd. by adding a few cc. of 30% H<sub>2</sub>O<sub>2</sub> to an almost satd. soln. of Na<sub>2</sub>MoO<sub>4</sub> cooled to 0°, and adding to this mixt. 2-3 min. later 150 cc. of pure EtOH, previously cooled to -5° to -10°. The red-brown permolybdate crystals are almost immediately pptd., filtered and washed with alc. and EtOH, cooled to -5° to -10°. Na<sub>2</sub>MoO<sub>4</sub> decomposes in air at 70-80° very rapidly, more slowly at room temp., and explosively at 100°. Na<sub>2</sub>MoO<sub>3</sub> is obtained as an intermediate product in the decompn. of Na<sub>2</sub>MoO<sub>4</sub> at lower temps. The best method is to spread the red Na<sub>2</sub>MoO<sub>4</sub> in a thin layer upon filter paper, allow the prepn. to stand at room temp. and stir periodically. After 2-8 days yellow Na<sub>2</sub>MoO<sub>4</sub>.nH<sub>2</sub>O is obtained. The heat of formation is 46 cal. for Na<sub>2</sub>MoO<sub>4</sub> and 92 cal. for Na<sub>2</sub>MoO<sub>3</sub>.

H. Stoertz

The formation of salts of amidoximes. I. Hippuramidoxime. J. V. Duhský and J. Trtílek. *Collection Czechoslov. Chem. Communications* 5, 310 16 (1933).—Hippuramidoxime (I), m. 123-6°, was prepd. from hippuronitrile and H<sub>2</sub>NOH, but could not be obtained free from Cl<sub>2</sub>. It gave a reddish violet color with aq. FeCl<sub>3</sub> and a brownish green ppt. with Cu(OAc)<sub>2</sub>. This Cu salt, with a ratio tp Cu:N of 1:3, contained 2 mols. of H<sub>2</sub>O, only one of which could be driven off below 100°, so the authors gave it the formula: C<sub>6</sub>H<sub>5</sub>CONHCH<sub>2</sub>-C(NH<sub>2</sub>)NOCuOH.H<sub>2</sub>O, and for the formula of I: C<sub>6</sub>H<sub>5</sub>-CONHCH<sub>2</sub>C(NH<sub>2</sub>)NOH. NiCl<sub>2</sub> alone has no action on I but the addn. of a little NH<sub>4</sub>OH causes a very slow formation of a red-violet ppt. This action is greatly accelerated by a little H<sub>2</sub>O<sub>2</sub>. This ppt. appears to be a mixt. of 2 nickelic salts: [C<sub>6</sub>H<sub>5</sub>CONHCH<sub>2</sub>C(NH<sub>2</sub>)NO]<sub>2</sub>.Ni<sup>III</sup>.NiOH and [C<sub>6</sub>H<sub>5</sub>CONHCH<sub>2</sub>C(NH<sub>2</sub>)NO]<sub>2</sub>.Ni.

John E. Millbery

## 7-ANALYTICAL CHEMISTRY

W. T. HALL

Progress in analytical chemistry during 1932. R. Fresenius. *Angew. Chem.* 46, 615 18 (1933).—A review with bibliography.

Karl Kammermeyer

Applications of the vacuum tube in potentiometric titrations. Kosaku Masaki and Okiro Hirabayashi. *Bull. Chem. Soc. Japan* 8, 245-54 (1933).—Contrary to common practice, a pos. potential was placed upon the grid with respect to the filament of the UX201A Mazda vacuum tube. The grid current, which was very small, flowed through the titrating cell and its function was to polarize the bi-metallic Pt electrodes that were substituted for the mono-metallic system. Polarized electrodes owe their effect in electrometric titrations to gas reactions upon the electrode surfaces. The p. d. between the electrodes must remain practically const. up to the equivalence point and this constancy of p. d. was accomplished by shunting a part of the grid current to the bi-metallic electrodes. No current flowed through the soln. when the drop in potential across the shunt was equal to the back e. m. f. due to polarization. One electrode was placed close to the buret to provide a slight difference in compn. of the soln. when the drop of soln. was added. The deflection of the needle of the galvanometer was temporarily unstable and great. But it again became stable if the addn. of the standard soln. was interrupted. Thus the approach of the end point was indicated.

H. E. Messmore

Notes on microchemical procedure. IX. L. Rosenthaler. *Mikrochemie* 13, 317-20 (1933); cf. C. A. 27, 2902.—Illus. KReO<sub>4</sub> forms difficultly sol. perhenates with certain alkaloids. Expts. show that KReO<sub>4</sub> cannot, however, be regarded as a general precipitant for alkaloids but in some cases ppts. are produced which, when examd. under

the microscope, can serve for the identification of the alkaloid. 8-Hydroxyquinoline in alk. soln. gives ppts. with many cations but unfortunately most of the ppts. have similar characteristics when examd. under the microscope. The characteristics of the ppts. with Ca, Ba, Sr, Cu, Pb, Cr, Ni and Cd are described. A sensitive test for CNS<sup>-</sup> is described which depends upon its oxidation to CN<sup>-</sup> by KMnO<sub>4</sub> and detection of CN<sup>-</sup> by means of AgNO<sub>3</sub>-methylene blue soln. It is also noted that volatile amines often give the spot tests recommended by Feigl for detecting Ni<sub>2</sub>.

W. T. H.

Application of semi-micro methods in analysis. M. Chaix. *Bull. soc. chim.* 53, 697 700 (1933).—Regret is expressed that the semi-micro methods of analysis have been neglected in France. Directions regarding app. and procedure are given for detg. C, H, N and halogens in org. substances.

W. T. H.

Quantitative drop analysis. I. General apparatus and technic. Paul L. Kirk. *Mikrochemie* 14, 1 14 (1933) (in English).—Suitable app. and technic are described whereby volumetric analysis can be carried out with reasonable accuracy when a single drop of a liquid sample is taken. The terminology is explained and it is proposed to use the Greek letter lambda to designate 0.001 ml. II. Determination of calcium. R. P. Müller and Paul L. Kirk. *Ibid.* 15-22 (in English).—A method suitable for detg. Ca in blood serum is described. Samples varied from 0.025 to 0.1 ml. and the results were within about 2% of the truth. The detn. was based on the pptn. of CaC<sub>2</sub>O<sub>4</sub> and titration of the ppt. with KMnO<sub>4</sub>.

W. T. H.

Quantitative micro-mineral analysis. Friedrich Hecht. *Mikrochemie* 14, 81-3 (1933).—A. A. Benedetti-Pichler.

*Ibid.* 84. Cf. Thurgwald and Benedetti, *C. A.* 25, 4200.—  
Polemical. W. T. H.

**Quantitative organic microchemical analysis in industrial problems.** W. R. Kirner. *Ind. Eng. Chem., Anal. Ed.* 5, 303-9 (1933).—The time and money saved by working with small quantities of material are illustrated by some practical examples and the history of the development of such work is outlined. W. T. H.

**The use of physical phenomena in chemical analysis.** A. Pignot. *J. usines gas* 53, 461-7 (1933).—A review of d., viscosity, surface tension, crit. soly. (aniline) and cryoscopic methods for analysis of oils; many references are given. B. J. C. van der Hoeven

**Analytical uses of color.** M. G. Mellon, G. W. Ferner and J. P. Mefflig. *J. Chem. Education* 10, 601-3 (1933).—Examples of the aid that color gives in controlling operations are shown and classified. W. T. H.

**Studies on the starch-iodine color test and its application to quantitative analysis.** Peter P. T. Sah. *Science Repts. Natl. Tsinghua Univ.* A2, 105-28 (1933).—Under carefully controlled conditions, the starch-iodine blue color is strictly proportional to the free I content, in accord with observations of Turner (*C. A.* 26, 1544). The starch soln. is first satd. with I to destroy reducing substances. Inorg. ions as well as KI influence the color and must be kept const. 0.01 N KMnO<sub>4</sub> is preferable to Br or Cl for oxidation of HI to HIO<sub>3</sub>, the excess being removed with 0.01 N (COOH)<sub>2</sub>. The method is most successful for amts. of 0.004 to 0.012 mg. I per cc. and has been applied to the detn. of I in blood, and in iodo-egg albumin. W. H. Adolph

**Twenty-five years of using Brandt's ferric oxide as a standard.** Otto Goeke. *Z. anal. Chem.* 94, 232-7 (1933).—It is now 25 years since Brandt described the prepn. and use of pure Fe<sub>2</sub>O<sub>3</sub> as a standard for KMnO<sub>4</sub> solns. It is still much used in Germany instead of Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. More than a dozen papers have been published regarding this standard and the gist of these papers is given here. W. T. H.

**Use of rhodizonic acid as indicator for the volumetric determination of barium.** A. Friedrich and S. Rapoport. *Mikrochemie* 14, 41-8 (1933).—The use of Ba rhodizonate as indicator for the titration of Ba<sup>++</sup> is difficult because the salt is in the form of a nearly insol. colloidal suspension which undergoes very slow reaction with sulfate. Moreover the ppt. becomes inactive by interference of the BaSO<sub>4</sub> formed. Titration of Ba<sup>++</sup> with sulfate in acid soln. gives values that depend upon the speed at which the titration is accomplished and the titration in neutral soln. is difficult because the color of the soln. at the end point changes rapidly and it is impossible to titrate to a given shade. By adding gelatin to the BaCl<sub>2</sub> soln. it is possible to prevent the pptn. of the Ba rhodizonate and keep in the sol state. The addn. of acid quickly destroys this but in neutral soln. better results are obtained in the titration when gelatin is present; even then it is not possible accurately to match colors at the end point. By pptg. Ba with an excess of Na rhodizonate in the presence of gelatin it should be possible to det. Ba colorimetrically bft the solns. are not very stable to light. W. T. H.

**Antimony as an indicator electrode in potentiometric titration of iron and aluminum.** E. W. Kanning and P. H. Kratli. *Ind. Eng. Chem., Anal. Ed.* 5, 381-3 (1933).—The Sb electrode satisfactorily indicates the end point in the titrations of AlCl<sub>3</sub> and FeCl<sub>3</sub> solns. by NaOH. Mixtg. of the 2 salts can be titrated approx. L. W. Elder

**Colorimetry.** Reinaldo Vanossi and Raoul Ferramola. *Ann. chim. anal. chim. appl.* 15, 481-95 (1933).—See *C. A.* 27, 40. W. T. H.

**Determination of very small quantities of substances.** Friedrich Emich. *Mikrochemie* 13, 283-8 (1933); cf. *G. A.* 27, 5674.—If an unweighable quantity of Ag<sub>2</sub>SO<sub>4</sub> is treated with BaCl<sub>2</sub> soln., a somewhat heavier residue of AgCl + BaSO<sub>4</sub> is obtained which, after treatment with H<sub>2</sub>SO<sub>4</sub> and heating, gives Ag<sub>2</sub>SO<sub>4</sub> again. By repeating the operation 10 times, the final wt. is 8.89 times as

large as that of the original Ag<sub>2</sub>SO<sub>4</sub>. Similarly an unweighable quantity of CaCO<sub>3</sub> yields on ignition an unweighable quantity of CO<sub>2</sub> but the residual CaO will absorb CO<sub>2</sub> which can be obtained again on heating so that by sufficiently repeating the process a weighable quantity of CO<sub>2</sub> can be obtained eventually. A trace of S can be converted to SO<sub>2</sub> by oxidation and the resulting SO<sub>2</sub> reduced to S by the action of SO<sub>2</sub>. The 3 atoms of S obtained from each S originally present can be subjected to the treatment over and over again. In detg. metals it is often advantageous to measure the H<sub>2</sub> evolved on treatment with acid. The methods of measuring extremely small vols. of gases are outlined. W. T. H.

**Colorimetric determination of aluminum.** F. Alten, H. Weiland and H. Looffmann. *Angew. Chem.* 46, 608-9 (1933).—Very small ppts. of Al hydroxyquinoline were detd. colorimetrically after a coupling reaction with diazo compds. in alk. soln. to strong yellow-red 5-aryazo dyes. Satisfactory detns. could be made in solns. contg. as little as 25-γ Al. Difficulties were encountered in the sepn. of Fe, but heating of the Fe- and Al-contg. soln. with NaOH caused pptn. of Fe(OH)<sub>3</sub> and satisfactory Al detns. could then be made, provided the soln. contained only Al<sup>+++</sup>, Fe<sup>+++</sup> and PO<sub>4</sub><sup>---</sup>. In the presence of Ca and Mg salts, too little Al was always found. The use of *urotropine* for the sepn. of the bivalent cations overcame this difficulty. Seven references. Karl Kammermeyer

**Rapid quantitative microanalysis of pure aluminum.** I. Determination of iron, copper and manganese. F. Pavelka and Hermine Morth. *Mikrochemie* 13, 305-12 (1933).—Directions are given for detg. Fe in the colorimeter by the depth of color produced with K<sub>3</sub>Fe(CN)<sub>6</sub> after dissolving the sample and oxidizing with H<sub>2</sub>O<sub>2</sub>, for detg. Cu by measuring the time required to decolorize a mixt. of Fe(CNS)<sub>3</sub> and Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> and for detg. Mn by means of the color produced by the action of (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub>O<sub>8</sub> and AgNO<sub>3</sub> in the presence of dil. H<sub>2</sub>SO<sub>4</sub>. W. T. H.

**Detection of small quantities of arsenic by the Gutzeit test.** G. Lockemann and H. Fr. v. Bulow. *Z. anal. Chem.* 94, 322-9 (1933).—A bibliography of 34 titles (dating from 1836 to the present) is given together with details for modifying the procedure so as to detect 10<sup>-7</sup> g. of As. W. T. H.

**Titrimetric determination of bismuth after precipitation as bismuth oxychloride.** E. v. Migray. *Chem.-Ztg.* 57, 774 (1933).—Evap. the soln. with HCl to convert the nitrates to chlorides, dissolve the residue in 100 cc. of water and barely sufficient concd. HCl to keep the Bi dissolved. If necessary, neutralize with NH<sub>4</sub>OH. Pour the soln. into about 200 cc. of boiling water. Filter off the resulting BiOCl. If Sb is present sufficient tartarate should be added to prevent SbOCl from forming. Dissolve the BiOCl in dil. HNO<sub>3</sub>, add an excess of Ag<sup>+</sup> and titrate the excess with KCNS soln. with ferric alum as indicator. W. T. H.

**Determination of small amounts of bismuth in copper.** L. C. Nickolls. *Analyst* 58, 684 (1933).—The reaction between H<sub>2</sub>SO<sub>4</sub> and KI gives a color which resembles the KBiI<sub>4</sub> color so that it is better to use SnCl<sub>2</sub> rather than H<sub>2</sub>SO<sub>4</sub> for the reduction of Fe<sup>+++</sup> prior to the colorimetric detn. of Bi. W. T. H.

**Determination of cadmium in the presence of zinc, in spelter and in zinc ores.** A. Pass and A. M. Ward. *Analyst* 58, 667-72 (1933).—To det. Cd in the presence of Group II metals, take 50 cc. of the soln. which is 2 N in H<sub>2</sub>SO<sub>4</sub>, add a few drops of H<sub>2</sub>SO<sub>4</sub>, boil and introduce a few clean Fe nails, replacing water lost by evapn. Keep just below boiling for an hr. Filter off PbSO<sub>4</sub> and pptd. metals through a sintered glass filter contg. a piece of Fe wire. Wash the residue with cold water. To the 100-120 cc. of filtrate add 5 g. of Rochelle salt, a few drops of H<sub>2</sub>SO<sub>4</sub> and 40-50 cc. of 0.2 N KI soln. Now, to form a ppt. of CdH<sub>2</sub>(C<sub>10</sub>H<sub>8</sub>N<sub>2</sub>)<sub>2</sub>, add sufficient 2.5% β-naphthaquinoline in 0.2 N H<sub>2</sub>SO<sub>4</sub> to provide an excess of 5-6 cc. in a total vol. of 140-150 cc. Allow the ppt. to settle for an hr., filter, wash thoroughly with a mixt. of 10 cc. 0.2 N KI, 10 cc. of the reagent, a few drops of

$\text{H}_2\text{SO}_4$  and 80 cc. of water. After draining well with the aid of suction, transfer the ppt. to the beaker in which pptn. took place and triturate with 20 cc. of 2 *N*  $\text{NH}_4\text{OH}$ . Filter and wash well with 2 *N*  $\text{NH}_4\text{OH}$  and water. Transfer the filtrate to a long-necked flask, rinse out the flask with 2 *N*  $\text{HCl}$ , using such an amt. (about 100 cc.) to make the soln. at least *N* in  $\text{HCl}$  at the end of the final titration. Add 5 cc. of 10%  $\text{KCN}$  soln. and some starch soln. Titrate with 0.025 *M*  $\text{KIO}_3$  soln. until the blue starch-iodide color that first develops turns to reddish violet (due to  $\text{HIO}$ ) and then colorless. One cc. of  $\text{KIO}_3 = 1.405$  mg. of  $\text{Cd}$ . By this procedure, not more than 50 mg. of  $\text{Cd}$  can be handled. *Detn. of Cd by means of phenyltrimethylammonium iodide.* Remove interfering metals by treatment with  $\text{Fe}$  as above. To the filtrate add 3 g.  $\text{KI}$  and 25-30 cc. of a 2.5% soln. of the reagent in water. After 6 hrs., filter and treat the ppt. in the same way as in the above procedure. The reagent has the same  $\text{Cd}$  equiv.

W. T. H.

**Magneto-optic Nicol rotation method for quantitative analysis of calcium.** Edna R. Bishop, C. B. Dollins and Irene G. Otto. *J. Am. Chem. Soc.* 55, 4365-70 (1933).—The magneto-optic method (cf. Allison and Murphy, *C. A.* 24, 5661) is based upon the time-lag differences of the Faraday effect behind the magnetic field in certain liquids as a function of the wave length of the light used. The necessary app. and procedure for detg.  $3.74 \times 10^{-4}$  to 1 mg. of  $\text{Ca}^{++}$  per cc. are described. Duplicate detns. agreed and checked with the values obtained by titrating  $\text{CaC}_2\text{O}_4$  ppt. within 10%.

W. T. H.

**Adaptation of the dimethylglyoxime-benzidine test for cobalt to the usual scheme of qualitative analysis.** Alfred W. Scott. *J. Am. Chem. Soc.* 55, 3047-8 (1933).—Evap. the soln. of  $\text{CoS} + \text{NiS}$  in aqua regia nearly to dryness, dissolve in a little water contg. 1 cc. of 6 *N*  $\text{AcOH}$ , add 1 g. of  $\text{NaOAc}$ , 0.5 cc. of 0.5% benzidine in alc. and an excess of dimethylglyoxime in alc. If  $\text{Co}$  is present, the filtrate from the  $\text{Ni}$  ppt. will be red.

W. T. H.

**Determining iron and the basicity in solutions of ferric salts.** A. L. Zaides and V. N. Sveshnikova. (*Otdelnie Tekhniki: Koshobuovoe Proizvodstvo* 1932, No. 4, 45-7. —Directions are given for reducing  $\text{Fe}^{+++}$  with  $\text{SnCl}_2$  and electrolytically. The basicity of  $\text{Fe}^{+++}$  solns. is detd. by titration with  $\text{NaOH}$  and when 3  $\text{NaOH}$  are required for each  $\text{Fe}^{+++}$  (as detd. by reduction followed by  $\text{KMnO}_4$  titration) the basicity is called 100%. The basicity can be determined (1) by electrometric titration with the glass electrode and (2) by alkalimetric titration in the presence of bromothymol blue.

A. A. B.

**Microelectrolytic determination of lead.** Hermann Brantner and Friedrich Hecht. *Mikrochemie* 14, 30-40 (1933).—A series of expts. shows that the microdetn. of  $\text{Pb}$  as  $\text{PbO}_2$  in  $\text{HNO}_3$  soln. is fraught with difficulties. For the microdetn. of  $\text{Pb}$ , therefore, the detn. as  $\text{Pb}$  picrolate is to be preferred to the electrolytic method.

W. T. H.

**Determination of small quantities of nickel in rock analysis.** H. F. Harwood and L. S. Theobald. *Analyst* 58, 673-82 (1933).—Digest 2 g. of fine powder in a Pt dish with 15 cc. of 18 *N*  $\text{H}_2\text{SO}_4$  and 20-25 cc. of pure  $\text{HF}$ . Heat on a sand bath, stirring frequently with a heavy Pt wire for the first 20 min. When the rock appears to be attacked completely, add a crystal of  $\text{KNO}_3$  and evap. to dense fumes. After fuming 10 min., cool, add sufficient water to dissolve the sol. salts and again evap. to fumes. Cool, add 100 cc. of water and heat until all sol. salts are dissolved. Filter if necessary, add 2-3 g. of citric acid and neutralize to methyl red by adding  $\text{NaOH}$ . Make barely acid with a few drops of dil.  $\text{H}_2\text{SO}_4$ , add 15 cc. of 1% dimethylglyoxime in alc. followed by 4 *N*  $\text{NH}_4\text{OH}$  until slightly ammoniacal. After standing 24 hrs. filter and wash with cold water. Dissolve the ppt. in a little hot, 7.5 *N*  $\text{HNO}_3$  and evap. as far as possible on the water bath after adding a few drops of 18 *N*  $\text{H}_2\text{SO}_4$ . Take up in water, filter if necessary, add 10 mg. of citric acid and 5-7 cc. of dimethylglyoxime reagent. Make barely alk. with  $\text{NH}_4\text{OH}$ , allow to stand overnight, filter, wash free from sulfate, dry at 120-130° and weigh. If the rock contains

more than 0.05%  $\text{NiO}$  it is best to det. the  $\text{Ni}$  content of the  $\text{Al}_2\text{O}_3$  ppt. or else make a detn. of the  $\text{Ni}$  content of the final filtrate after removing  $\text{Mg}$ . This value subtracted from the total  $\text{Ni}$  content should give the  $\text{Ni}$  adsorbed by the  $\text{Al}$  ppt.  $\alpha$ -Furil dioxime can replace dimethylglyoxime to advantage, especially when the  $\text{Ni}$  content of the rock is low. As little as 0.0025%  $\text{Ni}$  can be detd. by the above procedure.

W. T. H.

**Analytical chemistry of rhenium. X. Determination of rhenium as the dioxide.** W. Geilmann and Loren C. Hurd. *Z. anorg. allgem. Chem.* 214, 280-8 (1933); cf. *C. A.* 27, 5026.—When  $\text{NaOH}$  is added to a soln. of  $\text{K}_2\text{ReCl}_6$  a ppt. of  $\text{ReO}_3$  results and this ppt. has sometimes been recommended for the detn. of  $\text{Re}$ . The studies described in this paper show that the pptn. of  $\text{Re}$  as  $\text{ReO}_3$  is not suitable as a basis for the exact detn. of  $\text{Re}$ .

W. T. H.

**Determination of graphitic silicon in a siliceous residue.** L. H. Callendar. *Analyst* 58, 580-94 (1933); cf. *C. A.* 27, 2405.—By treating graphitic  $\text{Si}$  with 40%  $\text{NaOH}$  and measuring the gas evolved in a modified Hempel gas-volumeter fitted with a pressure-temp. compensator it is possible to obtain 0.16 cc. of  $\text{H}_2$  (S. T. P.) for each 0.1 mg. of  $\text{Si}$  present. The results agree within about 0.3% and consequently this method of analysis is by far the best at present available for the detn. of graphitic  $\text{Si}$  in a siliceous residue such as is obtained in the analysis of  $\text{Al}$ .

W. T. H.

**Determination of small quantities of selenium in sulfide ores.** Karl Brückner. *Z. anal. Chem.* 94, 305-22 (1933).—A study was made of the sources of error involved in the methods of detg.  $\text{Se}$ . It was found that loss of  $\text{Se}$  occurs when solns. are boiled with  $\text{HCl}$ , when solns. contg. mineral acids are evapd. to dryness and when the residues are heated in the drying oven. Difficulties occurring when the attempt is made to deposit  $\text{Se}$  from solns. contg.  $\text{HNO}_3$  or aqua regia can be overcome by fuming with  $\text{H}_2\text{SO}_4$  after which a complete pptn. of  $\text{Se}$  can be obtained. As a result of these studies, the following rapid and accurate method is proposed: Take 20 g. of ore in a beaker with high side walls and treat with 125 cc. of cold, concd.  $\text{HNO}_3$ , added in small portions during about 10 min. Heat the soln. to boiling and carefully add 60 cc. of concd.  $\text{H}_2\text{SO}_4$ . Evap. on the sand bath to fumes. Cool, dil. to 300 cc., add 20 cc. of concd.  $\text{HCl}$ , boil till the salts dissolve, dil. to 400 cc. with hot water and filter. At 60°, introduce  $\text{SO}_2$  for 10 min., add 3 cc. of a 10% soln. of  $\text{NH}_3$ ,  $\text{NH}_4\text{H}_2\text{O}$  and allow to cool. Filter off the impure  $\text{Se}$  and treat the filter and ppt. with a mixt. of 10 cc.  $\text{HCl}$  and 5 drops of concd.  $\text{HNO}_3$ . Heat on the water bath till the filter paper is well disintegrated and ppt. the  $\text{Se}$  again by adding 2 cc. of 10%  $\text{NH}_3$ ,  $\text{NH}_4\text{H}_2\text{O}$ . Filter, dry at 105° and weigh the  $\text{Se}$ .

W. T. H.

**Determination of tin by precipitation as stannous sulfide.** Benedikt Linke and Heinrich Preissecker. *Z. anal. Chem.* 94, 238-9 (1933).—Directions are given for dissolving com.  $\text{Sn}$  in concd.  $\text{HCl}$ , reducing the soln. with  $\text{Mg}$  powder, pptg. black  $\text{SnS}$  with  $\text{H}_2\text{S}$ , filtering and igniting to  $\text{SnO}_2$ . The results obtained by this procedure were a little lower than those obtained by the method of Löwenthal.

W. T. H.

**A new titrimetric determination of zinc.** E. Aster. *Verföhrer* 6, 236-7 (1933).—The method of Lang for  $\text{Zn}$  (*C. A.* 27, 3419) is described and recommended. Check detns. are given.

B. J. C. van der Haegen

**Qualitative analysis of small quantities of minerals. II. Detection of small quantities of zinc with dithizone.** Günther Rienacker and Werner Schiff. *Z. anal. Chem.* 94, 409-15 (1933).—If a neutral or dil.  $\text{AcOH}$  soln. of  $\text{Zn}^{++}$  is treated with a soln. of diphenylthiocarbazone in  $\text{CCl}_4$ , the green color of the  $\text{CCl}_4$  soln. changes to red if  $\text{Zn}$  is present. As little as 0.025  $\gamma$  of  $\text{Zn}^{++}$  can be detected.  $\text{Cu}$ ,  $\text{Pb}$  and  $\text{Hg}$  give similar coloration effects and the test can be obtained with most samples of distd. water. If an alk. soln. of  $\text{ZnO}$ ,  $\gamma$  is treated with the reagent, both the aq. and  $\text{CCl}_4$  phases are colored reddish and if the color of the aq. phase is taken as the criterion, as little as 0.0055 mg. of  $\text{Zn}$  can be detected. As reagent  $\gamma$  soln.

of 10 mg. dithizone in 100 cc. of  $\text{CCl}_4$  is suitable. To a few drops of the soln. to be tested, add 0.5 cc. of 2 *N*  $\text{NaOH}$  and 0.5 cc. of dithizone and shake vigorously. If Cd, Cu or Hg is present, first treat the soln. with  $\text{H}_2\text{S}$  in the presence of acid, filter off the sulfide ppt. and test the filtrate for Zn. The test is suited for detg. Zn in the usual systematic qual. procedure. III. Detection of tantalum and columbium. *Ibid.* 415-22.—To detect Ta in the presence of Ti, fuse the oxide with about 3 times as much  $\text{KHSO}_4$ , cool, add a few drops of concd.  $\text{H}_2\text{SO}_4$ , evap. to fumes and repeat these last operations several times. Then add 1.5 cc. of a mixt. of equal parts 10%  $\text{H}_2\text{SO}_4$  and 3%  $\text{H}_2\text{O}_2$  and allow to stand 15 min. Filter through a Jena glass filter. To the filtrate add 1 cc. of water and 1 cc. of 0.2 *N*  $\text{H}_2\text{SO}_4$ , heat to boiling and add, while boiling, 3 cc. more of the  $\text{H}_2\text{SO}_4$  in small portions. After 10 min. boiling, the presence of Ta will be indicated by the formation of a flocculent ppt. Dil. with a little water and boil 5 min. longer. Under these conditions Ti and Cb will not give ppts. when Ta is absent but in the presence of Ta, considerable Cb is adsorbed with the  $\text{Ta}_2\text{O}_5$ .  $\text{WO}_3$  will ppt. from a tungstate but, unlike  $\text{Ta}_2\text{O}_5$ , dissolves easily in dil.  $\text{NaOH}$  soln. If more than 3 parts of  $\text{SiO}_2$  are present in the soln. the pptn. of  $\text{Ta}_2\text{O}_5$  may be prevented but this is not likely to happen in mineral analysis.  $\text{H}_3\text{PO}_4$  hinders the pptn. From a soln. of  $\text{HAcO}$  buffered with  $\text{NaOAc}$ , a flocculent red ppt. is obtained on adding a half-satd. soln. of alizarin in  $\text{KtOH}$  if trivalent Cb is present. To test for Cb, therefore, fuse with  $\text{KHSO}_4$  and digest with  $\text{H}_2\text{SO}_4$  as in the Ta test. Take up the melt in 0.5 cc. of a mixt. of equal parts 20%  $\text{H}_2\text{SO}_4$  and 3%  $\text{H}_2\text{O}_2$ , filter if necessary and treat with an excess of Zn filings until there is no further evolution of  $\text{H}_2$ . Add 0.5 cc. of a satd. soln. of alizarin in  $\text{KtOH}$  which has been dild. with an equal vol. of  $\text{KtOH}$ . Remove any undissolved Zn and finally add 0.4 cc. of 10%  $\text{H}_2\text{SO}_4$ , 1 drop of satd. Na tartrate soln. and 0.5 cc. of satd.  $\text{NaOAc}$  soln. Dissolve any alk. salts that are pptd. by the  $\text{KtOH}$  by adding sufficient water and heat the clear soln. to boiling. After standing for an hr. in a closed test tube, red flakes of  $\text{Cb}_2\text{O}_3$  will be obtained when Cb is present. The above procedures were tested with samples contg. 0.2-1 mg. of  $\text{Ta}_2\text{O}_5$  or  $\text{Cb}_2\text{O}_3$  in the presence of other constituents likely to interfere. The alizarin lake formed in the Cb test does not appear to be other than an adsorption compd. but the Cb appears to be in the trivalent condition. W. T. H.

Behavior of zirconium, thorium and certain rare earths toward quinalizarin. A. S. Kumarovskii and I. M. Korenman. *Z. anal. Chem.* 94, 247-9 (1933).—Sensitive tests were obtained in test tubes and on filter paper for Nd, Pr, Ce, La, Zr and Th. Obviously quinalizarin cannot be used for detecting Be in the presence of these earths (cf. Fischer, *C. A.* 22, 4299). W. T. H.

Titration of iodine in the presence of iodide and iodate. Eugen Chirnoagă. *Z. anal. Chem.* 94, 252-5 (1933).—To det. total  $\text{I}_2$ , first add  $\text{Na}_2\text{SO}_3$  until the soln. is nearly decolorized by the reduction of free  $\text{I}_2$  and of  $\text{IO}_3^-$  to  $\text{I}^-$ . Add starch indicator and titrate with  $\text{AgNO}_3$ . This preliminary titration serves to det. the approx. content which appears a little late under these conditions. Titrate a fresh portion, adding the starch when the end point is near. Next titrate the free  $\text{I}_2$  in another portion of the original soln. If the soln. contains iodate and iodide, take the soln. in which the free  $\text{I}_2$  has been titrated, add  $\text{H}_2\text{SO}_4$  and titrate the  $\text{I}_2$  set free by the action of  $\text{IO}_3^-$  on  $\text{I}^-$ . The total  $\text{I}$  can also be detd. by the Volhard method; in this case add an excess of  $\text{AgNO}_3$  and allow the soln. to stand until the  $\text{AgI}$  ppt. is no longer reddish in shade but a pure yellow. This may require 12 hrs. Finally titrate the excess  $\text{Ag}^+$  with  $\text{KCNS}$ , using  $\text{Fe}^{+++}$  as indicator. W. T. H.

Volumetric determination of small quantities of inorganic iodide. Joseph F. Sadusk, Jr., and Eric C. Ball. *Ind. Eng. Chem., Anal. Ed.* 5, 386-8 (1933).—A careful study of the Winkler method shows that it is accurate for detg. small quantities of  $\text{I}_2$ . As a practical result of

this study, directions are given for analyzing iodised salt which is prescribed for the prevention of endemic goiter. Dissolve 5 g. of salt in water and add 2 *N*  $\text{H}_2\text{SO}_4$  until a pink color is imparted to the soln. Add 2 ml. more of the acid and a few glass beads. Pass a stream of air through a gas-washing bottle contg. pure  $\text{Br}_2$  and into the reaction flask through a tube ending just above the soln. and, by swirling the content of the flask, allow the soln. to absorb sufficient  $\text{Br}_2$  from the vapors to impart a yellow color to the soln. but avoid an excess. Then boil the soln. until the yellow color disappears and for 2 min. longer. Cool, wash down the sides of the flask with water sufficient to restore the original vol., add 2 ml. of freshly prepd.  $\text{KI}$  soln. and titrate the liberated  $\text{I}_2$  with 0.005 *N*  $\text{Na}_2\text{S}_2\text{O}_3$  soln. Add starch indicator toward the last. W. T. H.

Microdetermination of iodine and a practical micro-drying oven. Wilhelm Münster. *Mikrochemie* 14, 23-6 (1933).—The method, like that of Vieböck and Brecher (*C. A.* 25, 896), depends upon the detn. of methoxyl but the app. used is somewhat different. Excellent results were obtained in the analysis of  $\text{C}_2\text{H}_5\text{O}_2\text{NI}$ ,  $\text{C}_2\text{H}_5\text{O}_2\text{N}_2\cdot 2\text{CHI}_2$  and  $\text{CHI}_3$ . The drying app. described is simple and easily constructed; it is suitable for drying of hygroscopic substances and for drying in a vacuum. W. T. H.

Determination of iodine values by the pyridine sulfate bromide method. Herbert Hawley. *Analyst* 58, 601 (1933).—Data are given to show that the method of Rosenmund and Kuhnenn (*C. A.* 18, 477) gives results which are reproducible but must be accepted with considerable caution when used for comparison with figures obtained by other methods. W. T. H.

Semi-microdetermination of nitrogen by the Dumas method. E. P. Clark. *J. Assoc. Official Agr. Chem.* 16, 575-80 (1933); cf. *C. A.* 27, 3680.—A detailed description is given of an app. and technic for a semi-micro N detn. by the Dumas method. A. P.-C.

Report on (the determination of) forms of nitrogen in plants. Hubert B. Vickery. *J. Assoc. Official Agr. Chem.* 16, 473-6 (1933).—A detailed description of the method of Pucher, V. and Wakeman (*C. A.* 26, 5876), which will be studied collaboratively. A. P.-C.

Detection of chloride in the presence of other halides. Wm. Brash. *Analyst* 58, 686 (1933).—Wash the Ag halide ppt. until free from sol. Ag salt, suspend it in water, add some  $\text{K}_2\text{Fe}(\text{CN})_6$  and a little  $\text{NH}_4\text{OH}$ . If the Ag ppt. contained  $\text{AgCl}$ , enough will dissolve to give a brownish ppt. of  $\text{Ag}_3\text{Fe}(\text{CN})_6$  which is much less sol. in  $\text{NH}_4\text{OH}$  than  $\text{AgCl}$  is. W. T. H.

Detection of iodide with paper impregnated with silver nitrate. Aurel I. Velculescu and Jeaneta Cornea. *Z. anal. Chem.* 94, 255-7 (1933).—If a piece of filter paper is moistened with 0.1 *N*  $\text{AgNO}_3$  soln. and then dried, a drop of a soln. contg.  $\text{I}^-$  will give a yellow spot. If  $\text{Br}^-$  and  $\text{Cl}^-$  are also present, the insol. halides are not pptd. together but in different zones. Thus the presence of 0.005 mg. of  $\text{I}^-$  in a drop of soln. can be detected in the presence of considerable  $\text{Cl}^-$  and  $\text{Br}^-$ . W. T. H.

Determination of small quantities of iodide and bromide in the presence of chloride, particularly in mineral waters.

Georg Lockemann and Theodor Kunzmann. *Z. anal. Chem.* 94, 385-96 (1933).—With bibliography. First, the  $\text{I}^-$  content is detd. colorimetrically by treating with  $\text{FeCl}_3$  and  $\text{HCl}$  and measuring the depth of color produced by action of the liberated  $\text{I}_2$  upon starch. Next, the total halide content is detd. by titration with  $\text{AgNO}_3$ . Finally, a series of 3 gravimetric detns. is made in which a measured vol. of standard  $\text{AgNO}_3$  soln. is added which is insufficient for the complete pptn. of all the halide present. In these ppts. the wt. of  $\text{AgI}$  is known from the results of the colorimetric detn. of  $\text{I}_2$ . When this wt. of  $\text{AgI}$  is deducted from that of the entire ppt., the  $\text{Br}^-$  content can be calcd. from the difference between the remaining wt. and that of  $\text{AgCl}$  corresponding to the vol. of  $\text{AgNO}_3$  added. The reason for making several tests is because the computation gives greater precision when the  $\text{AgCl}$  in the ppt. is not large in comparison with that of the  $\text{AgBr}$ . W. T. H.

Application of the potential-forming system metal-metal anion to potentiometric titrations. I. Precipitation-potentiometric titration of chromate, molybdate and tungstate anions, as well as of a series of metal ions, with chromium, molybdenum and tungsten as indicator electrodes. H. Brintzinger and E. Jahn. *Z. anal. Chem.* 94, 396-403 (1933).—The set-up recommended provides for the use of a normal calomel cell against an electrode of Mo, W or Cr-plated alloy steel. With  $\text{BaCl}_2$  as titrating reagent,  $\text{CrO}_4^{2-}$  can be detd. with a Cr-plated electrode and  $\text{MoO}_4^{2-}$  with an electrode of Mo. Since Ba, Sr, Pb, Cu, Cd and Mn give ppts. with  $\text{MoO}_4^{2-}$ , these cations can be detd. by titrating with  $\text{Na}_2\text{MoO}_4$ . All these titrations were carried out at 95°. W. T. H.

Titrimetric determination of perchlorate. Microdetermination of potassium. Adolf Bolliger. *Z. anal. Chem.* 94, 403-8 (1933).—The method described for titrating  $\text{HClO}_4$  is suitable for detg. K in biol. materials when the org. material has been decompd. by heating with  $\text{HClO}_4$ . The  $\text{KClO}_4$  ppt. is dissolved in water and the soln. is treated with a measured vol. of methylene blue chloride. The resulting ppt. is filtered off and the excess reagent is titrated with picric acid soln. The fact that methylene blue perchlorate or picrate can be shaken out with  $\text{CHCl}_3$ , although methylene blue and picric acid are both insol. in this solvent, permits a sharp recognition of the end point. Details are given for detg. as little as 1 mg. of  $\text{HClO}_4$ . W. T. H.

Determining the basicity of ferric salts in the presence of ferrous salts. A. A. Sorokina. *Ovladenie Tekhniki: Koshobuvnoe Proizvodstvo* 1932, No. 4, 47-8.—The basicity is detd. by first converting  $\text{Fe}^{++}$  into  $\text{Fe}^{+++}$  by treatment with  $\text{H}_2\text{O}_2$ , removing the excess by heating and titrating the oxidized soln. with 0.1 N NaOH while hot with bromothymol blue as indicator. A. A. B.

Action of hydriodic acid on the difficultly soluble sulfates. Earle R. Caley. *J. Am. Chem. Soc.* 55, 3947-52 (1933).—Sulfates of Ba, Sr, Ca, Pb and Cr are much more sol. in hot concd. HI than in HCl or HBr of the same strength. The sulfate is reduced to  $\text{H}_2\text{S}$  with liberation of  $\text{I}_2$ . J. W. Shipley

Determination of sulfide in zinc sulfide by the expulsion method. J. L. Buchan. *Analyst* 58, 682-4 (1933).—It has been stated by some chemists that the evolution method when used to det. the ZnS content of paints and lithopones gives values which are somewhat too low. Some expts. with the method show that it is accurate but some com. samples of pure ZnS contain only 80-90% of this substance. The procedure followed was essentially the same as the well-known evolution method for detg. S in steel except that a stream of  $\text{H}_2$  is recommended for sweeping all the  $\text{H}_2\text{S}$  into the ammoniacal Cd soln. W. T. H.

Argentometric titration of selenous cyanides with adsorption indicators by the method of Fajans. Raluca Ripan. *Z. anal. Chem.* 94, 335-7 (1933).— $\text{AgSeCN}$  is about as insol. in water as  $\text{AgI}$  but when an excess of  $\text{Ag}^+$  is present, there is pptn. of Ag. To titrate by Fajans' method, add 1-2 drops of 0.2% fluorescein in alc. and titrate with  $\text{AgNO}_3$ . After adding the first few drops, the soln. will remain clear for some time but a silky, cryst. ppt. will form on shaking. Continue adding the reagent dropwise while shaking. A fugitive red color will appear on adding the  $\text{Ag}^+$  and the color will become more persistent as the end point is approached. When the ppt. becomes more flocculent in appearance, the end point is near. A good color change is obtained at the end point. The soln. titrated should be 0.1-0.005 M in  $\text{SeCN}^-$ . W. T. H.

The potentiometric determination of selenous cyanides. Raluca Ripan. *Z. anal. Chem.* 94, 331-4 (1933).— $\text{SeCN}^-$  can be titrated potentiometrically with accuracy with  $\text{AgNO}_3$  as in the case of halides. The Ag salt of this pseudo halide is very difficultly sol. and is stable as long as no excess of  $\text{Ag}^+$  is present. One must wait after each addn. of reagent but when proper precautions are taken, the results of the titrations are excellent. W. T. H.

Methods for the qualitative analysis of the hydrogen sulfide group. Johannes Kunz. *Helv. Chim. Acta* 16, 1044-9 (1933).—Although NaCl has been often recommended for "salting out" colloids too little attention has been paid to the use of NaCl in preventing pptn. or in dissolving ppts. A table is given showing the  $\text{H}^+$  concn. at which the sulfides of the Cu-Sn group begin to form, the  $\text{H}^+$  concn. at which pptn. is complete and the  $\text{H}^+$  concn. at which the ppts. redissolve. According to this table, the pptn. of  $\text{SnS}$  is only complete when the soln. is 0.25 N. In the absence of NaCl, pptn. of CdS and PbS is complete in N  $\text{H}^+$  but when considerable NaCl is present the soln. should not be over 0.15 N for complete pptn. of CdS or 0.25 N for complete pptn. of PbS. The values for  $\text{Cu}_2\text{S}$  and  $\text{CuS}$  agree, which indicates that from  $\text{Cu}^{++}$  solns. a mixt. of  $\text{Cu}_2\text{S}$  and S is formed rather than  $\text{CuS}$  as is commonly assumed.  $\text{Hg}_2\text{Cl}_2$  ppts. from solns. that are 12 N in HCl and  $\text{HgS}$  from 6 N HCl.  $\text{As}_2\text{S}_3$  and  $\text{As}_2\text{S}_5$  also ppt. from 12 N HCl. In pptg. with  $\text{H}_2\text{S}$  it is recommended to make sure that the Sn is present in the fully oxidized state. For sepg. the Sn from the Cu group it is recommended to mix 2 cc. of 2 N KSH soln. with 8 cc. of 2 N KOH and dil. to 40 cc. This serves to dissolve the sulfides of Hg, Sn and Sb.  $\text{HgS}$  is pptd. from the soln. by diluting and boiling. By adding exactly 11 cc. of 12 N HCl,  $\text{As}_2\text{S}_3$  is pptd. and recognized as usual. Then by adding 24 cc. of water to the 16 cc. of filtrate, the Sb is pptd. on adding  $\text{H}_2\text{S}$  and the Sn is pptd. by adding 2 N  $(\text{NH}_4)_2\text{S}$  soln. By digesting the residue insol. in KSH with 5 cc. of 12 N HCl, the sulfides of Bi, Pb and Cd are easily dissolved and black Cu sulfide remains. It is recommended to wash the ppt. with strong NaCl soln. until 60 cc. of filtrate is obtained. Then on adding  $\text{H}_2\text{S}$  water,  $\text{Bi}_2\text{S}_3$  is pptd. which can be identified by dissolving in 2 N  $\text{HNO}_3$ , adding Rochelle salt, NaOH and either formaldehyde soln. or dextrose to ppt. Bi. In the Pb-Cd soln. the insol. basic carbonates can be formed by boiling with  $\text{Na}_2\text{CO}_3$  soln. On washing the ppt. with dil.  $\text{H}_2\text{SO}_4$ , insol.  $\text{PbSO}_4$  is formed and Cd can be detected in the filtrate by adding  $\text{H}_2\text{S}$  water. W. T. H.

Colorimetric determination of hydrogen sulfide, sulfides and thiosulfates. André Giberton. *Compt. rend.* 197, 646-8 (1933).—If a soln. of  $\text{Na}_2\text{S}_2\text{O}_3$  is treated with  $\text{AgNO}_3$  soln., the ppt. of  $\text{Ag}_2\text{S}_2\text{O}_3$  which forms first is soon changed to black  $\text{Ag}_2\text{S}$  and S. This takes place rapidly even in a cold, dil. soln. A small  $\text{Ag}_2\text{S}$  ppt. can be dissolved in KCN soln. and then on adding  $\text{Na}_2\text{PbO}_2$  and gelatin a brown colloidal ppt. of PbS can be formed which can be used for colorimetric comparison. This method of getting colloidal PbS has been used previously for detg.  $\text{S}^{--}$  and  $\text{HS}^-$  but the above method of forming it from  $\text{Na}_2\text{S}_2\text{O}_3$  may be used advantageously for prepg. suitable standards, because if the original quantity of  $\text{Na}_2\text{S}_2\text{O}_3$  is known, the  $\text{Ag}_2\text{S}$  and PbS formed correspond to one mol. of sulfide for each mol. of  $\text{Na}_2\text{S}_2\text{O}_3$  present at the start. W. T. H.

A very sensitive test for boric acid, studied in connection with a biochemical problem. Fr. Hahn. *Compt. rend.* 197, 762-4 (1933).—When isoalk. solns. of  $\text{H}_3\text{BO}_3$  and of a polyhydroxy compd. which can combine with  $\text{H}_3\text{BO}_3$  are mixed, the  $p_a$  of the mixt. is lower than that of the original solns. Heat a 1:1 glycerol-water soln. to boiling, add phenolphthalein and then 0.01 N NaOH to a persistent light red color; add phenolphthalein to the soln. to be examd. and bring to the same shade by addn. of 0.01 N NaOH or HCl; on mixing the 2 solns. complete decolorization occurs with as little as  $5 \times 10^{-4}$  g. B per cc. With bromothymol blue (adjusted to the transition color) instead of phenolphthalein and recrystd. mannitol instead of glycerol, the sensitiveness is  $2 \times 10^{-3}$  g. B per cc., and, with 1 drop of each soln. on a porcelain plate to make the test, the actual amt. that can be detected is  $10^{-3}$  g. The most delicate test previously known is sensitive to only  $6 \times 10^{-4}$  g. B. The action of B in the germination of the pollen of tropical white water lilies (Schmucker, C. A. 27, 751) possibly involves intermediate combination of the trace of B with:

one polyhydroxy compd. contained in the pollen.

A. Papineau-Couture

**Bromometric titration of sulfide acids.** Nils Hellström. *Svensk Kem. Tids.* 45, 157-69 (1933).—Mercapto and sulfide org. acids of the types RSH, RSR, RSSR, —CH<sub>2</sub>—SR, and RS(CH<sub>2</sub>)<sub>2</sub>SR (R is CH<sub>2</sub>COOH, etc.) when reacted with standard KBrO<sub>3</sub> and titrated iodometrically gave theoretical S values. The Br equivs. are, resp., 1, 2, 10, 12 and 4. When the acids were titrated potentiometrically (Pt-HgCl) the breaks in the voltage curve agreed with the theoretical vols. of KBrO<sub>3</sub> soln. equiv. to the S present.

A. R. Rose

**Methods for analyzing antiferrous metals.** P. Foerster. *Ann. chim. anal. chim. appl.* 15, 441-6 (1933).—Suitable methods for detg. Sn and Sb are described. W. T. H.

**New method for the analysis of industrial phosgene.** Costin D. Nenitzescu and Constantin Pana. *Bul. soc. chim. Romania* 15, 45-8 (1933).—The mixt. of COCl<sub>2</sub> and Cl<sub>2</sub> is drawn through a previously weighed tube contg. metallic Sb. This tube is connected to an absorption bulb contg. 20 cc. of a 10% soln. of alc. potash, and carrying a tube filled with silica gel to prevent escape of vapors from the absorption bulb. These 2 are weighed together before the detn. After running the mixt. to be analyzed through the app. for 5 min., dry air is drawn through to insure complete removal of the COCl<sub>2</sub> from the tube contg. the Sb. The gain in wt. of the tube contg. the Sb represents the wt. of Cl<sub>2</sub> in the mixt. Likewise, the gain in wt. of the absorption bulb and the silica gel tube represents the wt. of COCl<sub>2</sub> in the mixt. As a check, the contents of the absorption bulb can be transferred to a volumetric flask, acidified with HNO<sub>3</sub>, diluted to vol., and an aliquot portion titrated by Volhard's method.

W. A. Moore

**Detection of a bank note forgery by ultra-violet light.** Julius Grant. *Analyst* 58, 663-4 (1933).—A clever forgery of a Chinese note of elaborate engraving printed in several colors showed under ultra-violet that different dyes had been used in making the counterfeit. The procedure is described.

W. T. H.

**Report on (the determination of) carbohydrates in plants.** J. T. Sullivan. *J. Assoc. Official Agr. Chem.* 6, 471-3 (1933); cf. *C. A.* 27, 215.—A study of the possible causes of error in the detn. of sucrose by the invertase method showed that: with some plant exts. it is not possible to obtain the max. reducing power in 2 hrs. (in 1 case max. reducing power had not been reached at the end of 24 hrs.); H-ion concn. does not seem to play an important part in the final reducing power obtained; a higher concn. of invertase may hasten hydrolysis, but it causes difficulty in the filtration of the reduced su. Insufficient data have been accumulated to raise the question of the specificity of the invertase prepn.

A. Papineau-Couture

**Report on (the determination of) lignin.** Max Phillips. *J. Assoc. Official Agr. Chem.* 16, 476-9 (1933); cf. *C. A.* 6, 2395.—Lignin was detd. by the previously described method by 3 analysts on 8 different lignified plant materials. The results showed that the accuracy of the method compares favorably with other known methods. It is suggested that attempts should be made to remove V-contg. substances either before or after treatment withuming HCl so as to avoid the necessity of detg. N in the lignin residue. Further collaborative work will be done before recommending adoption of the method as official.

A. Papineau-Couture

**The ter Meulen method for direct determination of oxygen in organic compounds.** W. Walker Russell and John W. Fulton. *Ind. Eng. Chem., Anal. Ed.* 5, 384-6 (1933).—The sample is vaporized in a stream of H<sub>2</sub> and caused to flow over a red hot surface and thence over a Ni catalyst whereby the oxides of C are converted into CH<sub>4</sub> and H<sub>2</sub>O; the H<sub>2</sub>O and CO<sub>2</sub> contents of the exit gases are measured by making improvements in the procedure, it has been found possible to obtain satisfactory results. A furnace recommended for volatilizing the original substance; a coated granular quartz forms a suitable cracking sur-

face and a very active, thoriated-promoted, Ni catalyst has proved helpful. With the improved app. excellent results were obtained in detg. the O content of succinic acid, oxalic acid, dextrose, sucrose, benzoic acid, anthraquinone, quinoxaline and  $\beta$ -naphthol. A bibliography of 15 titles is given.

W. T. H.

**Microanalytical determination of methoxyl groups in liquid compounds.** A. F. Colson. *Analyst* 58, 594-600 (1933).—Expts. in detg. OCH<sub>3</sub> in a liquid such as anisole by the app. and technic recommended by Pregl gave unsatisfactory results caused by the tendency of some of the liquid to distil unchanged from the reaction vessel. Various modifications were tried until finally an app. and technic were developed whereby accurate results could be obtained. The reaction vessel is fused on to a fairly wide tube contg. glass beads wetted with 1.5 ml. of HI, d. 1.7. The excess is allowed to drain into the reaction flask and is finally poured out through a side tube which is fused to the reaction flask. The gas from the flask passes through the fairly long tube contg. glass beads into 2 traps contg. a 5% soln. of CdSO<sub>4</sub> with a little red P in suspension and from thence into AgNO<sub>3</sub> soln. The reaction vessel is charged with 0.2 ml. of Ac<sub>2</sub>O, 40 mg. of phenol, 1.5 ml. of HI, d. 1.95 and 2 small pieces of porous plate. The liquid to be analyzed is weighed in a small glass-stoppered tube which is introduced into the reaction vessel through the side tube. A current of CO<sub>2</sub> is passed through the app. at a rate not exceeding bubbles of gas per sec. in the AgNO<sub>3</sub> soln. The flask is heated in a glycerol bath and maintained at 125-135° for 45 min. The resulting ppt. of AgI is weighed with the usual precautions.

W. T. H.

**Determination of ethyl alcohol in fusel oil.** John M. Macoun. *Analyst* 58, 664-6 (1933).—To 20 ml. of the oil in a 50-ml. Eggertz tube graduated in 0.1 ml. intervals, add 5 g. of K<sub>2</sub>CO<sub>3</sub>. Mix well and add more carbonate if it all dissolves. If too much has been added so that there is no line of demarcation between the 2 liquid phases, add water sufficient to make 2 layers. After the sepn. is complete, read the vol. of the upper layer. It is fusel oil plus 93% EtOH by vol. Measure out another 20 ml. portion into a "tar acid flask" of 225 ml. capacity which is graduated from 0 to 25 ml. in not more than 0.2 ml. intervals. Add a satd. soln. of fusel oil in satd. NaCl aq. soln. until the flask is about  $\frac{3}{4}$  full. Add 4-5 ml. of concd. HCl followed by exactly 5 ml. of petr. ether. Shake well and add sufficient NaCl soln. to make the total vol. 225 ml. Shake well, let stand and tap the sides of the flask to get a good sepn. into layers. Read the upper layer. Let A represent the contraction from 20 ml. observed in the Eggertz tube, and B the contraction from 25 ml. observed in the flask. Then the percentage of EtOH by vol. is  $(B-A) \times 0.93 \times 5$ . The method is shown to be better than that recommended in Allen's *Commercial Organic Analysis*.

W. T. H.

**Microdetermination of ethyl alcohol and of glycerol with the aid of colorimetry and the photoelectric cell containing selenium.** R. Fonteyne and P. de Smet. *Mikrochemie* 13, 289-304 (in French).—The colorimetric detn. of EtOH is based upon the measurement of the excess K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> used to oxidize the alc. For this purpose a sensitive photoelec. colorimeter is recommended for use with monochromatic light. With this app., which is described in detail, it is possible to det. 0.1-2 g. of EtOH per l. within about 2 mg. of the truth. The detn. of glycerol is more difficult because glycerol is harder to oxidize completely. The step-photometer of Pulfrich can be used for these detns. but with less accuracy.

W. T. H.

**Detection and determination of tribromoethanol.** Herbert Collatz. *Biochem. Z.* 265, 199-202 (1933).—CBr<sub>3</sub>CH<sub>2</sub>OH or avertin has important therapeutic uses. It is eliminated as a glucuronate. A method is offered for converting the CBr<sub>3</sub>CH<sub>2</sub>OH to bis-hydrazone of glyoxal. A 100 mg. % soln. of avertin is heated 6 hrs. in a paraffin bath under a reflux with a soln. of 0.4 g. 2,4-dinitrophenylhydrazine in 2 N HCl and the hydrazone crystals are filtered off, dried and weighed. This yields up to

78.7% of the theoretical. With 0.4 g. *p*-nitrophenylhydrazine dissolved in 12 cc. 30% AcOH together with 0.4 g. NaOAc, and heating 7 hrs. under reflux on a water bath, the yield of hydrazine crystals is up to 93% of the avertin fixed.

**Microdetermination of acetone.** A. Lindenberg. *Compt. rend. soc. biol.* 114, 15-18(1933).—A slight modification of the Messinger-Huppert iodometric method is described. As little as 0.01 mg. Me<sub>2</sub>CO can be detd. with a possible error of about 1%. L. E. Gilson

**Determination of some phenols by weighing aristol.** Maurice François and Laure Seguin. *Bull. soc. chim.* 53, 711-23(1933).—When thymol is treated with I<sub>2</sub> dissolved in KI soln. a product called aristol is formed. Similar products are formed with other phenols. Details are given for detg. guaiacol, guaiacol carbonate,  $\alpha$ -naphthol and  $\beta$ -naphthol by such a reaction; a glass filtering crucible is recommended for filtering the ppt. The resulting compds. did not always have the expected compn. but there was a definite relationship between the wt. of ppt. and that of the original phenol. W. T. H.

**An accurate and simple method for the determination of invert sugar in the presence of sucrose.** O. Spengler and F. Todt. *Z. Ver. deut. Zuckerrind.* 83, 833-45(1933).—A review is given of the various factors that influence the amt. of Cu<sub>2</sub>O pptd. by sucrose and invert sugar from Fehling's soln. Expts. were carried out with (1) sucrose, (2) invert sugar, (3) sucrose + invert sugar to study the effect of (a) various amts. of Fehling soln., (b) boiling temp. as affected by atm. pressure and added talcum powder and (c) time of heating on the amt. of Cu<sub>2</sub>O produced. Various substitutes for Fehling soln. were also studied. The results showed that the sucrose had a reducing power that was greatly influenced by (a), (b) and (c), while the pptg. power of the invert sugar is practically independent of such conditions. Systematic expts.

are recommended to study the effect of (1) the  $p_{H}$  of the soln. used to treat the sugar product, (2) the Cu-ion concn. and (3) the working conditions. It was found that the accuracy of the detn. of invert sugar in the presence of sucrose would be greatly increased if, instead of the 2 min. boiling period, the sample were removed from the flame as soon as boiling starts. F. C.-C.

**Analysis of mixtures of Schaeffer and F acids—effect of these acids in depressing the phenol-water critical solution temperature.** Douglas G. Kerr. *J. Soc. Chem. Ind.* 52, 336-8T(1933).—The differentiation of Schaeffer acid ( $\beta$ -naphthol-6-sulfonic acid) from F acid ( $\beta$ -naphthol-7-sulfonic acid) has been impossible. It has been found, however, that they depress the crit. soln. temp. to different extents and at low concns. the depression is linearly proportional to the acid concn. To analyze a mixt. of the 2 acids, add equal wts. of various mixts. to 2.575 g. of phenol and 5 cc. of water and plot the temp. at which the soln. becomes opaque. From this graph the compn. of any mixt. can be detd. W. T. H.

**Electrometric titration of sulfurous, selenious and  $\alpha$ -hydroxyalkylsulfonic acids.** P. Rumpf. *Compt. rend.* 197, 686-9(1933).—By working with the glass electrode and titrating H<sub>2</sub>SeO<sub>3</sub> with NaOH, it was possible to detect good inflection points at  $p_{H}$  2.4 and 8 corresponding to the titration of an ordinary dibasic acid. This acid gave no ppts. with various aldehydes. With H<sub>2</sub>SO<sub>3</sub>, only the complete neutralization of the second H<sup>+</sup> could be detected with the glass electrode as the end point of the first H<sup>+</sup> is at too low a  $p_{H}$ . When H<sub>2</sub>SO<sub>3</sub> is coupled with an aldehyde, the product acts as a strong monobasic acid but the acid is too strong for successful titration with the glass electrode. W. T. H.

Breakdown of org. As compds. [estn. of PhCH<sub>2</sub>AsO<sub>2</sub>H<sub>2</sub>] (England) 10. Viologen indicators (Michaelis, Hill) 10.

## 8 - MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

**A new method for recognizing the structure of carnallite rocks.** F. Bessert. *Kali* 27, 239-40(1933). Carnallite may be distinguished from sylvite, halite, etc., by heating to 160°. MgO, formed by hydrolysis, covers the carnallite with a white crust. Kieserite undergoes hydrolysis above 200°.

**Tridymite as a slag mineral.** C. W. Carstens. *Centr. Mineral. Geol.* 1933A, 321-2.—Crystals of tridymite were identified in a slag contg. 47% FeO, 35% SiO<sub>2</sub> and small amts. of CaO, Al<sub>2</sub>O<sub>3</sub>, Cu, Zn and S. Fayalite and pyroxene were also present. Michael Fleischer

**Synthetic rutile.** Karl Chudoba and Werner Wisfeld. *Centr. Mineral. Geol.* 1933A, 323-6.—Excellent crystals of rutile, d. = 4.24, were formed on passing a dry 1:1 mixt. of TiCl<sub>4</sub> and O<sub>2</sub> through a porcelain tube at 650-750°. Forms (110) and (111) predominated; and pseudo-rhombic twinning on (101) was frequent. Michael Fleischer

**The chemical constitution of pectolite.** D. S. Belyankin and V. P. Ivanova. *Centr. Mineral. Geol.* 1933A, 327-39.—A pectolite, of mol. compn. (Na,K)<sub>2</sub>O 1.00, H<sub>2</sub>O 1.14, (Ca,Mn)O 4.16, SiO<sub>2</sub> 6.14%, was heated from 100° to 1000°. Only 0.27% of the 0.00% total H<sub>2</sub>O was lost at 600°, photomicrographs and measurement of  $n$  showing no change in structure. At 700° and above, nearly all the H<sub>2</sub>O was lost, the mineral decomposing into  $\beta$ -wollastonite and glass. Conclusion: The H<sub>2</sub>O is not zeolitic, but H<sub>2</sub>O of constitution, and the formula of pectolite is HNaCa-Si<sub>2</sub>O<sub>6</sub>. Michael Fleischer

**Differential thermal analysis of montmorillonitic clays (bentonites).** J. Orsel and S. Caillère. *Compt. rend.* 197, 774-7(1933); cf. C. A. 21, 878; 27, 4103.—Thermal differential analysis by Le Chatelier's method (*Bull. soc. franc. minéral.* 10, 204 11(1887)) was applied to a no. of montmorillonitic clays and to synthetic mixts. of montmorillonite and kaolinite. The curves obtained can show the presence of as little as 3% kaolinite, which

could not be detected by other methods; the sensitiveness for montmorillonite is only about 20%. The curves obtained show that kaolinite and montmorillonite can have been formed under the same physico-chem. conditions, and that, in a fairly large no. of cases, it is impossible to distinguish sharply between kaolinite clays and montmorillonite clays. A. Papineau-Couture

**The present condition of mining in Brazil.** F. W. Freire. *Berg- u. Hüttenm. Jb. Leoben* 80, 1 7(1932); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 607-10.—Analyses of Fe ores from Minas Geraes, of Mn ores, Ni ores, Cr ores, S ores and Au ores are included. J. F. S.

**Auriferous formation in the region of the Arassuahy River and of Minas Novas, Minas Geraes.** Luciano Jacques de Moraes. *Ann. acad. brasil. sci.* 5, 51-3 (1933).—A geological description is given. The ore nets 13.2 g. Au and 17.8 g. Ag per ton. John M. Ladino

**The Sadon silver-lead-zinc deposit.** V. Domarev. *Trans. Geol. Prospecting Service U. S. S. R.* 10, 1-00 (1930); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 480-2.—An analysis of sphalerite and data on the Pb, Zn and Ag contents of ores are given. J. F. Schairer

**The Suleiman-sai lead-vanadium deposit in Kazakhstan.** E. Yanishevskii. *Trans. Geol. Prospecting Service U. S. S. R.* 109, 1-34(1931); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 592-6.—Analyses of V and Pb-Zn ores, are given. J. F. Schairer

**Iron ores at Itabira, Brazil.** Bernhard H. Sander. *Bull. Inst. Mining Met.* No. 349, 1-8(1933); cf. C. A. 27, 4756.—Discussion. Alden H. Emery

**The iron range in Eastern Transbaikalia.** P. Kasatkina and S. Smirnov. *Mining J. (Moscow)* 106, 101-7 (1930); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 574-5.—Many analyses of Fe ores are included. J. F. Schairer

**The characteristics of the Dashtesan iron-ore deposit**

from a magnetometric survey (1923-1924). D. Ortenberg. *Trans. Geol. Prospecting Service U. S. S. R.* 11 (1930); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 471-3.—Several analyses of Fe ores are given.

J. F. Schairer  
Silicate nickel ores of the Tülsenevsk deposits in the Urals. E. Kuznetsova. *Bull. Geol. Prospecting Service U. S. S. R.* 50, 265-85 (1931); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 482-4.—Analyses of garnierite and several types of Ni ores are given.

J. F. Schairer  
The Rej chromite district. M. Gordienko. *Mining J. (Moscow)* 106, 118-22 (1930); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 467.—The ore contains 15-50%  $\text{Cr}_2\text{O}_3$ .

J. F. Schairer  
Chrome minerals of Outokumpu. Pentti Eskola. *Bull. comm. geol. Finlande* No. 103, 26-41 (1933).—Serpentine rock overlying the ore deposits of the Outokumpu Cu mine in eastern Finland is intersected by quartzite, dolomite and graphite-bearing schist. It is evident that the serpentine is the source of the numerous Cr minerals present, although this rock itself is singularly free from Cr except for pigment-like secondary products. The most notable occurrences are veins composed of uvarovite, tawnaite, Cr-tremolite, Cr-diopside and chromite. These minerals are probably of hydrothermal origin, and illustrate the ability of Cr to migrate and take part in metasomatic replacements. Many analyses and 18 references are included.

1 The structure, inclusions and alteration of the Deer Creek intrusive, Wyoming. John P. Rouse. *Am. J. Sci.* 26, 139-46 (1933).—A laccolith of medium-grained quartz-diorite-porphry is intruded in Tertiary, basic breccias and basalt flows. It is composed of varying amts. of plagioclase, hornblende needles, biotite and quartz. The central zone is a much decayed mass of quartz-diorite. The computed norms of the outer fresh rock and the inner decayed zone, resp., are: quartz 20.82, 21.83, orthoclase 13.90, 12.84, albite 38.25, 36.29, anorthite 16.68, 17.02, corundum 0.61, 0.72, hypersthene 4.76, 4.13, magnetite 2.32, 1.85, ilmenite 0.61, 0.61, hematite 0.00, 0.64, apatite 0.62, 0.67, and calcite, 0.00, 0.10. The decayed zone is due to hydrothermal alteration of the rock above the stem that fed magma to the laccolith.

Alden H. Emery  
Petrography and petrology of the Mount Devon diabase porphyry. Garrett A. Mulenburg and Samuel S. Goldich. *Am. J. Sci.* 26, 355-67 (1933).—The Mount Devon dike was intruded as a porphyritic magma. Three generations of plagioclase are distinguishable. Secondary products, uraltite, sericite, chlorite, etc., were derived from the primary minerals and glass was derived by the action of hydrothermal solns. Alteration was most intense in the central porphyritic zone. The large phenocrysts are much sericitized and show enrichment in  $\text{K}_2\text{O}$ . Pseudomorphs, largely chlorite, have been developed as a secondary structure. The alteration is an end phase of dike intrusion; the solns. were derived from the main reservoir from which the dike magma was extruded.

Genetic relations between the crystalline limestones, dolomites and amphibolites in the rock series at Chynov. Al. Orlov. *Věstník Král. Čes. Spol. Nauk.* II Kl. 36 pp. (1931); *Neues Jahrb. Mineral. Geol.* 1932, Referate 2, 388-91.—Numerous chem. analyses of rocks are included.

J. F. Schairer  
Hydrothermal metamorphism of an ultra-basic intrusive at Schuyler, Virginia. H. H. Hess. *Am. J. Sci.* 26, 377-408 (1933).—The alteration of an ultra-basic rock to form soapstone is described. The changes took place under conditions of decreasing temp. The order of replacement was pyroxene, green hornblende, actinolite, chlorite and talc—each mineral stable over a temp. range lower than its predecessor. Pressure and stress were of secondary importance. The solns. which permitted the alterations to take place must have been dil., consisting of  $\text{H}_2\text{O}$ , some  $\text{CO}_2$  and little else; other original constituents probably were removed during a long migration from a distant acid intrusion, the source of the solns. Alteration of a gabbro to amphibolite probably is due usually to hydrothermal rather than dynamometamorphism, except as shearing opens paths for solns.

Alden H. Emery  
Parallel striations on etched limestone surfaces. Paul H. Dunn. *Am. J. Sci.* 26, 442-6 (1933).—Striations formed on overhanging facets of limestone or calcite placed in HCl (1:10-1:40) mark the path of rising  $\text{CO}_2$  bubbles.

## 9--METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

- Historical outline of basic processes in metallurgy. L. Guillet. *Mém. compl. rend. soc. ing. civils France* 85, 1227-35 (1932). --An address. A. Papineau-Couture
- Twenty-five years' progress in metallurgy at Broken Hill, N. S. W. M. R. McKeown. *Chem. Eng. Mining Rev.* 25, 11-18 (1933). Historical. W. H. Boynton
- Compilation of important specific heats for metallurgical calculations. C. Schwurr. *Arch. Eisenhüttenw.* 7, 281-92 (1933). --Formulas for sp. heat and heat contents for air,  $O_2$ ,  $N_2$ ,  $CO$ ,  $H_2$ ,  $CO_2$ ,  $SO_2$ , steam,  $CH_4$ ,  $C_2H_4$ ,  $C_2H_2$  and  $C_2H_6$ , and for Al, Cu, Cr, C, Fe, Mg, Mn, Mo, Ni, Si, Sn, W, Zn and a no. of oxides and slags are compiled from the most recent data available. Forty-four references. M. Hartenheim
- Minerals Yearbook, 1932-33. O. E. Kressling, et al. *Bur. Mines* 519 pp. (1933). --Production for 1932 is given, compared with previous years and discussed for Au, Ag, Cu, Pb, Zn, secondary metals, Fe, Al, Hg, Mg, Mn, Mo, W, Sn, Cr, Sb, As, Ru, U, V, Pt, and allied metals, Ni, minor metals and ore concn. Alden H. Emery
- Notes on power used in crushing ore, with special reference to rolls and their behavior. John S. Owens. *Bull. Inst. Mining Met.* No. 348, 1-2 (1933); cf. C. A. 27, 3172. --Discussion. Alden H. Emery
- The practice of flotation. G. B. O'Malley. *Chem. Eng. Mining Rev.* 25, 46-9 (1933). --A review. W. H. Boynton
- Milling methods and costs at the Alaska Mine flotation plant of the Southern Rhodesia Base Metals Corporation, Limited, S. Rhodesia. C. P. McMillin. *Bull. Inst. Mining Met.* No. 349, 15 pp. (1933). --The ore treated is malachite and chrysocolla in the oxidized zone and chalcocite with an occasional speck of chalcopryrite and pyrite in the sulfide zone. Native Cu also occurs. For the yr. ending March 31, 1931, heads averaged Cu 3.31%, Ag 10.3 dwt. per ton. By flotation, 81.4% of the Cu and 83.6% of the Ag are recovered in a concentrate assaying 68.2% Cu and 215.3 dwt. Ag; the tailings carry Cu 0.64% and Ag 1.87 dwt. Reagent consumption is xanthate 0.356 lb. per ton, cresol 0.186 lb., tar oil 0.250 lb. and creosote 0.108 lb. Total costs were 79.49 d. *Ibid.* No. 350, 15-23. Alden H. Emery
- Study of the flotation of bituminous copper ores of the type of Mansfeld and Niedermarsberg. A. Cotte and G. Aletan. *Mettall u. Erz* 30, 383-9 (1933). --Conditions required for the flotation of these ores are stated. The ores contain about 74.3%  $SiO_2$ , 10.9%  $Al_2O_3$ , 1.8% Cu, 0.002% Ag and 5.8% carbonaceous material. H. S.
- Surface actions of some sulfur-bearing organic compounds on some finely ground sulfide minerals. A. M. Gaudin and Walter D. Wilkinson. *J. Phys. Chem.* 37, 833-45 (1933). --Galena reacts with xanthates to form Pb xanthates which are extd. with acetone. The xanthate readily changes to S and unidentified oils. Galena abstracts dioxanthogen from aq. suspension. Pyrite changes xanthate to dioxanthogen. Sphalerite does not abstract xanthates from soln. Chalcocite abstracts isomyl monosulfide from aq. suspension and part of the reagent can be extd. unchanged from the treated mineral. Some of the changes appear to require atm. O. P. T. N.
- The development of mining and treatment of copper ores at Mt. Lyell, Tasmania. R. M. Murray. *Chem. Eng. Mining Rev.* 25, 5-10 (1933). A review that shows that complex siliceous ores can now be profitably treated with the same Cu content as the pyritic ores of 25 yrs. ago. W. H. Boynton
- The slags from lead and copper ore smelting. Wilhelm Völker. *Arch. Eisenhüttenw. Erzaußereit. Metallhüttenw.* 1, 163-90 (1931). --A crit. review. J. G. A.
- Reduction of iron ores with hydrogen and carbon monoxide. F. Wicner. *Arch. Eisenhüttenw.* 7, 275-9 (1933). The whole course of reduction of pure and ordinary hematite ore in H and CO was studied by examn. of etched samples taken at short intervals. At temps. below 570° the reduction to Fe in H progresses from the edges toward the center; at higher temps. the Fe formation begins at points all over the structure. Reduction with CO produces a different distribution of the metallic Fe in the FeO than that with H; Fe appears, at all temps., at single points which increase in size with increasing temp. Etched specimens can, therefore, indicate accurately the kind of reducing gases and temp. Disintegration of ores in CO is effected by the gas pressure produced on account of the selective permeability of the lattice structure for CO and  $CO_2$ . This disintegration was observed with H only at high temp. and to a small degree. Eight references. M. Hartenheim
- Degradation of "black" Portuguese uranium ores. A. Pro Leite. *Chimie et industrie Special No.* 805 (June, 1933). --When this ore is treated with  $H_2O$ , the quantity of U dissolved is a function of the sulfate content (formed by oxidation of sulfide S); P (as phosphate) begins to dissolve only above a certain sulfate content; the time of immersion has no effect on solubilization of P and U; solubilization of U takes place more readily in natural than in distd.  $H_2O$ ; bicarbonate has no effect on the solubilization of U. A. Papineau-Couture
- The non-ferrous metal manufacturing industries of Australia. Clement Blaisey. *Chem. Eng. Mining Rev.* 25, 29-33 (1933). --A brief review of the principal establishments where rolling, drawing and extruding of non-ferrous metals are or have been carried on. W. H. B.
- Production and deposition of indium. Wm. S. Murray. *Ind. Eng. Chem., News Ed.* 11, 300 (1933). The com. process of obtaining In involves mining, flotation concn., roasting of the concentrate, dissolving the sol. portion of the roasted concentrate with  $H_2SO_4$  and throwing out the In by metallic replacement or by neutralization. The impure ppt. is dissolved, purified and plated out of soln. A typical cyanide plating bath is: 5 oz. (142 g.) In as double cyanide, 9 oz. (255 g.) free cyanide or equiv. of NaCN, 2.5 oz. (71 g.) sugar and water to make 1 gal. (3.78 l.). The deposit of In is soft, uniform and gray. W. H. Boynton
- Gold in Canada. A. H. A. Robinson. *Can. Dept. Mines, Miners Branch, Rept.* 734, 92 pp. (1933). Alden H. Emery
- The development of gold mining in Morobe, New Guinea. Harold Tylour and I. W. Morley. *Bull. Inst. Mining Met.* 347, 61 pp. (1933). --Metallurgical practice is described briefly. Alden H. Emery
- Progress in the metallurgy of gold. B. H. Moore. *Chem. Eng. Mining Rev.* 25, 43-5 (1933). --Developments, during the past 25 yrs., in crushing and grinding, and Au extn. are noted. The recognition of the necessity for and the value of systematic and continuous exptl. research into all phases of the processes in use and the adaptation of the results of such research and of scientific principles to practical operations are of paramount importance. W. H. Boynton
- A history of the introduction of the MacArthur-Forrest cyanide process to the Witwatersrand gold fields. Jas. Gray and J. A. McLachlan. *J. Chem. Met. Mining Soc. S. Africa* 33, 375-97; 34, 74-5 (1933). A. H. Emery
- Some observations upon the use of potassium ferrocyanide as a coagulant in the assay of gold-bearing solutions and in the treatment of slimes residues for total gold assay. C. T. Creed and C. F. Cayton-Boxall. *J. Chem. Met. Mining Soc. S. Africa* 33, 308 (1933); cf. C. A. 27, 4497. --Discussion. Alden H. Emery
- Native wire silver: Notes on its formation and possible significance. C. B. P. Douglas. *Bull. Inst. Mining Met.* No. 348, 3 (1933); cf. C. A. 27, 4501. --Discussion. Alden H. Emery
- Practical "test" manipulation. Handling the cupella-

tion furnace. C. E. Downie. *Chemistry & Industry* 1933, 777-8. J. H. Moore

The sodium-carbonate process for treating cast iron. E. W. Colbeck and N. L. Evans. *Foundry Trade J.* 49, 191-2(1933).—Pouring molten cupola metal into ladles contg. a mixt. of  $\text{Na}_2\text{CO}_3$  and ground limestone is shown to offer several advantages. Downs Schaff

Study of nitrogen in the Thomas process. O. Quadrat and M. Pilz. *Chimie & industrie Special No.*, 694-7 (June, 1933).—In 45 tappings from 3 blast furnaces the av. N content was 0.0010%. The changes in N content during the manuf. of steel were studied on 25 charges by taking samples from (1) the cast Fe leaving the mixer, (2) the steel in the converter before deoxidation, (3) the same after deoxidation, (4) the steel remaining in the converter after pouring and (5) a small test ingot. The N contents found were: (1) 0.0017, (2) 0.0171, (3) 0.0105, (4) 0.0161, (5) 0.01601%. The greatest increase in N in the converter occurs during the final third of the blowing period. A study of N segregation in a small ingot showed that N tends to accumulate in the center, being 0.0171% at the surface and 0.0188% at the center. A. Papineau-Couture

The Thomas converter process. P. Piérard. *Mém. compt. rend. soc. ing. civils France* 85, 1236-9(1932).—An address. A. Papineau-Couture

The basic open-hearth process. L. Baclé. *Mém. compt. rend. soc. ing. civils France* 85, 1240-4(1932).—An address. A. Papineau-Couture

Installation and organization of a modern steel works laboratory. P. Chevenard. *Mém. compt. rend. soc. ing. civils France* 85, 1109-58(1932).—A detailed description of the Imphy lab. of the Soc. de Commentry-Fourchambault & Decazeville, its organization, equipment and methods used, with an outline of the results of some of the investigations carried out. A. Papineau-Couture

Progress in the metallurgy of steel. R. Perrin. *Mém. compt. rend. soc. ing. civils France* 85, 991-7(1932).—Dephosphorization of Thomas steel can be obtained by violently agitating the steel with a very fluid, basic, oxidizing slag; e. g., P was reduced from 0.060 to 0.012% practically instantaneously. By proper application of the process dephosphorization can be obtained even with high P contents; several treatments are used in series if necessary; the treatment leads to practical equil. between the metal and slag, which is indispensable for obtaining uniform results. One of the main essentials is extremely violent agitation, failing which the results are most irregular. Deoxidation of steel can be obtained by: (1) recarburization, (2) converting part of the dissolved Fe oxide into another oxide sol. in the steel and finally (3) agitating the steel violently with a fluid acid slag for a very short time. A superoxidized steel can thus be transformed, without addn. of a stilling agent, Si, Al or Ti, into a mild steel contg. about 0.150% Si and 0.001-0.002% O. Regeneration of the slag charged with oxides dissolved from the steel can be obtained by adding excess of a deoxidizer (e. g., Si or Al) and again shaking very violently for a very short time. The deoxidation of the steel and regeneration of the slag are thus effected by means of 2 short but very violent agitations, with an intermediate addn. of a deoxidizer; the latter does not cause inclusions in the steel, as the  $\text{SiO}_2$  or  $\text{Al}_2\text{O}_3$  formed dissolves in the slag. The process also lends itself to the introduction of special elements in the steel. A. P.-C.

Basic slags of Siemens-Martin furnaces. J. Bulina. *Chimie & industrie Special No.*, 672-8(June, 1933).—B. studied the effect of the chem. compn. of the slag and of temp. on the FeO concn. in the slag and in the fused steel in the transformation of cast Fe into malleable Fe in a basic furnace. Operation of the furnace was controlled by complete analysis of samples of different malleabilities. FeO was detd. via Herty et al. (*C. A.* 22, 1309). The concn. was found to depend on the  $\text{CaO}:\text{SiO}_2$  ratio. If this ratio (after subtracting the CaO combined as  $\text{Ca}_3(\text{PO}_4)_2$ ) = 1.76 the FeO and  $\text{Fe}_2\text{O}_3$  are merely dissolved in

the molten slag; if it is greater than 1.70 part of the Fe loses its oxidizing power and passes into the inactive form. The slag then consists of 2 phases: the fused mass and the solid suspension. Under these conditions it is the fused mass that possesses the oxidizing power of the slag. The ratio between the free FeO and the inactive FeO is governed by the laws of absorption. A. P.-C.

The fluidity of slag and processes of refining steel. L. Losana. *Met. ital.* 25, 405-14(1933).—Viscosity measurements have been made on slags from acid as well as basic Martins furnaces, and elec. furnaces. The viscometer consists of a graphite rod rotating in the molten slag under the impetus of a definite weight. The distance a pointer moves along the horizontal scale in a certain time is a measure of the viscosity. The basic slag had the compn.:  $\text{CaO}$  43,  $\text{Al}_2\text{O}_3$  7.0,  $\text{SiO}_2$  50%; m. p. 1440°; viscosity at 1500° —7.1; 1600° —6.3; 1650° —5.1; and at 1700° —3.5; these values are compared with those of water at 20°. The effect of addn. of  $\text{FeO} + \text{Fe}_2\text{O}_3$  (3.95-28.94%) was measured. Viscosity increases with increasing oxide from 3.0 to 6.3 (at 1500°); and from 1.2 to 2.8 (at 1700°). Replacing Fe oxide with  $\text{MnO}$  up to 15% does not alter the viscosity appreciably, but above this amt., it increases with increasing  $\text{MnO}$ . The viscosities of a no. of com. slags, acid, basic, and from elec. arc furnaces, were also detd. Slags with high FeO and low CaO have higher viscosity than when the CaO is also high. This may be due to decompn. of a very basic silicate, as  $3\text{FeO}:\text{SiO}_2$ , giving FeO and  $2\text{FeO}:\text{SiO}_2$  or  $\text{FeO}:\text{SiO}_2$ . With higher CaO, the  $\text{SiO}_2$  is combined with both oxides, so that only  $\text{FeO}:\text{SiO}_2$ , which is more stable at higher temps., is formed. The effect of adding varying amts. of a fluorspar ( $\text{CaF}$  92.64,  $\text{CaCO}_3$  2.96,  $\text{H}_2\text{O}$  4.01,  $\text{Fe}_2\text{O}_3$  0.36%) caused a drop in viscosity with addn. of up to 5%; but at 10% the viscosity again rises, except when high  $\text{SiO}_2$  is present. Therefore, there is an optimum amt. of fluorspar which may be added as flux, which increases as the percentage of  $\text{SiO}_2$  in the slag increases. A. W. C.

The transparency of sulfide and oxide inclusions in steel. C. Benedicks and H. Löfquist. *Jernkontorets Ann.* 116, 443-57(1933).—In photomicrographs of oxide or sulfide slag inclusions, certain series of parallel lines are sometimes observed. These are shown to be due to interference phenomena on transparent wedge-shaped slabs. By measuring the distances between the lines the  $n$  may be calcd. For light of wave length  $0.53 \mu$ , the value of  $n$  for  $(\text{Fe}, \text{Mn})\text{O}$  was found to be  $2.1 \pm 0.1$  and for  $\text{MnS}$ , 2.4. Nine references. H. C. Duus

Drill steels for mining purposes. W. H. Hatfield. *Bull. Inst. Mining Met.* No. 348, 5-7(1933); cf. *C. A.* 27, 4200.—Discussion. Alden H. Emery

The present status of our knowledge regarding the structure of metals and alloys and its industrial consequences. Albert Portevin. *Mém. compt. rend. soc. ing. civils France* 85, 7-42(1932).—An address. A. P.-C.

Metallographic grinding with paraffin impregnated with abrasives. R. L. Dowdell and M. J. Wahl. *Metals & Alloys* 4, 181-2(1933). Downs Schaff

The action of energizers during case carburization. E. G. Mahin and Joseph A. Toussaint. *Proc. Indiana Acad. Sci.* 42, 113-17(1933).—CO is the only important direct carburizing agent and results in the carburizing mixt. from the reactions  $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$ , and  $\text{CO}_2 + \text{C} \rightleftharpoons 2\text{CO}$ . By the time the carburizing temp. of C and air is reached a very small proportion of  $\text{O}_2$  remains in contact with the C; at 850° only 14% of the original  $\text{O}_2$  remains; hence the small carburizing effect without the use of energizers.  $\text{Na}_2\text{CO}_3$ ,  $\text{CaCO}_3$ ,  $\text{BaCO}_3$ ,  $\text{CaO}$  and  $\text{BaO}$  serve well to increase the speed of C absorption. The above carbonates, upon heating, slowly give off  $\text{CO}_2$  which furnishes CO for absorption. The oxides, at 600-700°, combine with the  $\text{CO}_2$  formed from  $\text{C} + \text{O}_2$  and at 800° there is a considerable proportion of carbonate ready to furnish  $\text{CO}_2$  for  $\text{CO}_2 + \text{C} \rightleftharpoons 2\text{CO}$  and at 850° there is carburization. H. E. Measmore

The finishing of metals used in aircraft. Harold Crary. *Metal Cleaning and Finishing* 5, 419-21(1933).—A de-

scription of the operations and the equipment employed in the finishing of parts for all-metal air craft. D. T.

**Modern trend in cast iron.** R. P. Bethell. *Proc. Staffordshire Iron Steel Inst.* 47, 2-9 (1931-32).—The chem. and phys. properties as required of good-quality pig iron are discussed. It is the general belief that irons have some inherent or intrinsic properties which are not revealed by the ordinary tensile and transverse tests usually carried out. It is recommended that all the raw materials entering the furnace be carefully graded. G. T. M.

**Heat treatment of cast iron.** J. H. Bradshaw. *Proc. Staffordshire Iron Steel Inst.* 47, 52-7 (1931-32).—A general discussion on microstructure, heat treatment, alloy cast iron and the application of the heat-treated cast iron. G. T. Motok

**Development of cast iron for machine construction.** Oliver Smalley and W. W. Kerlin. *Iron Age* 132, 24-7 (1933).—A structural analysis of cast iron or semi-steel may contain: ferrite 2-56, Fe silicide 2-10, pearlite 0-85, cementite 0-43, P eutectic 0-48 14.95, MnS 0.09 0.67, FeS 0.06-0.21 and graphite 0-10.7%. Phys. properties of the structural constituents are tabulated. Chem. analysis, structural analysis, and phys. properties of highest cast iron, autocylinder cast iron, gears, and white iron castings are listed. Factors affecting the design include compression, fatigue, rigidity, wear, hardness, corrosion, heat resistance, machinability, magnetic properties, heat treatment and mass effect. C. B. Jenni

**Some properties of alloyed gray cast iron.** Carl Pfannen-schmidt. *Giesserei* 20, 473-81 (1933); cf. C. A. 27, 5040. Curtis L. Wilson

**The effect of hydrogen on the transformation of iron.** R. H. Harrington. *Trans. Am. Soc. Steel Treating* 21, 896-8 (1933).—A reply to Esser and Cornelius (C. A. 27, 5097). W. A. Mudge

**Rates of scale formation on iron and a few of its alloys.** K. Heudlhofer and B. M. Larsen. *Trans. Am. Soc. Steel Treating* 21, 865-98 (1933).—Scaling is considered a diffusion process. The thickness of each layer, hence the thickness of the whole scale, increased as the square root of time and increases rapidly with rising temp. according to an exponential relation. These simple relations are not strictly valid for alloys or for sharply curved surfaces such as wires. Conclusions are confirmed for pure Fe and pure Cu and a few Fe alloys by expts. in which relatively long periods of exposure and continuous weighing of the sample during the scaling period are used. The greater rate of scaling in steam is probably connected with the fact that the scale formed in steam is more porous. C up to 1.00% has no effect upon scaling rate. Ni up to 35% or Al at 5-7%, reduces scaling to  $\frac{1}{2}$   $\frac{1}{2}$  of the amt. for pure Fe. Al above 12-14% and Cr at 27% decrease scaling to 0.01 that for pure Fe. W. A. Mudge

**Fatigue and the hardening of steels.** Herbert J. French. *Trans. Am. Soc. Steel Treating* 21, 899-946 (1933).—An appraisal of the process of martensitization and age hardening is given in terms of the resistance of steels to fatigue. Delayed fractures (after 10 million stress repetitions) in martensitized steels are discussed in relation to fatigue-testing technique and the utilization of hardened and slightly tempered steels. Methods are given for detg. "probable damage lines," that is, the ranges of overstress within which damage should not occur. Hard martensites are shown to require appreciable proportions of retained austenite, or decomposition products, for high resistance to fatigue. The fatigue limits produced by age hardening Cu-Si and Ni-Al steels, at around 400 Brinell, were approx. the equiv. of those of martensitized and tempered steels at the same hardness but their resistance to occasional overstress was not so good. Strengthening on overstressing in fatigue tests, reported occasionally by earlier investigators, was observed in temper-brittle Ni-Si steels. Evidence is presented in support of the hypothesis that strengthening by overstressing, or initially high ratios of fatigue limit to tensile strength, were the result of aging effects, that is, the decay of super-satd. solid solus. initiated by slip. Particle deposition in

the slip bands was conceived to obstruct slip and so to improve the resistance to fatigue. W. A. Mudge

**Production of rustproof steels.** Edward Maurer. *Z. Elektrochem.* 39, 820-2 (1933). Reply. B. Strauss. *Ibid.* 822. Correct position. Ed. Maurer. *Ibid.* 822-4; cf. C. A. 21, 3591.—A controversy over the discoverer of rustproof steels. H. Stoertz

**Modern high-grade structural steels.** P. Schoen-maker. *Ingenieur* 48W, 141-7 (1933).—A review of various German and American special steels for construction use, Ni steel, Si steel, etc. Strength, corrosion resistance and other qualities are discussed; tables and references are given. B. J. C. van der Hoeven

**Molecular compounds in liquid steel and their influence on the deoxidation equilibria.** P. Hercasymenko and F. Potohil. *Collection Czechoslov. Chem. Communications* 5, 331-8 (1933).—A thermodynamic study of the Fe-Si-O system. Investigation of the liquidus-solidus curves of the Fe-Si system near the m. p. of Fe shows that Si dissolved in Fe is mainly in the form of FeSi. But only at. Si can take part in the deoxidation:  $2\text{FeO} + \text{Si} = 2\text{Fe} + \text{SiO}_2$ . Further, if Mn is present it will combine with some of the Si to form Mn<sub>2</sub>Si (where x is probably 2 or 3). The authors conclude, therefore, that the deoxidizing effect of Si in liquid steel contg. Mn is considerably lower than in steel without Mn. This is confirmed by exptl. data taken from various sources. Bibliography. John E. Milbery

**Titanium and columbium in plain high-chromium steels.** Frederick M. Becket and Russell Franks. *Am. Inst. Mining Met. Engrs., Tech. Pub.* 506, 14 pp. (1933).—W and Mo addns. to Cr steel inhibit air hardening slightly. Their carbides are fairly sol. in Fe-Cr solid soln., and on cooling from high temps. these carbides ppt. in finely divided form, preventing the steel from becoming soft and ductile in the hot-rolled condition. Plain Cr steel and high-Cr steel contg. W or Mo can be softened through proper annealing. Suitable proportions of Zr, Ta and V afford greater improvement than W and Mo. Approx. 20 times as much Ta as C is needed, a prohibitive cost. V must be used in a ratio of 15:1 of C, but this decreases the resistance of steel to oxidation at high temp. Large amts. of Zr are needed and this introduces undesirable amts. of Si. Ti should be present in the ratio of 5-7 times the percentage of C, Cb 8-10 times. Smaller ratios afford some improvement; large excesses are detrimental through hardening of the solid soln. of Fe and Cr. The high-Cr steels contg. Ti or Cb may be hot-worked easily. Phys. properties of these steels are shown tabularly. The addn. of 0.00% Ti to 5.93% Cr steel raised the Ac<sub>1</sub> point from 803 to 808° and on cooling raised the Ar<sub>1</sub> point from 436° to 841°. Cb gives similar results. A. H. Emery

**Harmful influence of phosphorus in steel.** W. Beckers. *Ingenieur* 48, 144-7 (1933).—Test pieces were made in an acid open-hearth furnace of cast steel of variable P content (the low-P samples in a basic furnace); all charges are carefully deoxidized (O less than 0.04%, S below 0.027%), chilled and annealed at a temp. 50° above the upper crit. point. The standard stress and impact tests were made, the results of which are given in tables and curves as a function of the percentage of P from 0 to 0.12%. The influence on elastic and impact strength was insignificant up to 0.00% P; the toughness is lowered somewhat but remains within reasonable limits up to 0.08% P. In the samples with more than 0.10% P made by addn. of ferro-phosphorus to the charge the curves drop rapidly; the mfg. method is believed to be responsible for this (Ober-hoffer, *Das techn. Eisen*, p. 208, C. A. 22, 2136). It is concluded that P contents of steel up to 0.08% are insignificant; addn. of P material to a finished charge is objectionable. B. J. C. van der Hoeven

**Field and laboratory data covering tests upon special alloys for barrels, balls and seats.** Walter F. Rogers. *Oil Gas J.* 32, No. 23, 54, 58, 59 (1933).—The use of Cr-Ni-Fe alloys for balls and seats makes replacements a negligible expense. Field data are given. J. R. S.

A critical study of some iron-rich iron-silicon alloys

Chu-Phay Yap. *J. Phys. Chem.* 37, 951-67(1933).—The following Fe-Si alloys, annealed for 150 hrs. at 900°, were studied: 12.4, 13.1, 14.0, 14.5 and 15.6 Si. In addn. to these alloys of high purity 3 com. alloys of 5, 25 and 32% Si were examd. By means of the thermoelec. method, electrode potential measurements and x-ray crystal analysis, it is concluded that the phase  $\psi$  (Fe<sub>3</sub>Si) is a compd. and not a distinguished point in a series of solid solns. The existence of an  $\eta$ -phase (Fe<sub>3</sub>Si<sub>2</sub>) and an  $\epsilon$ -phase (FeSi) is indicated by electrode potential measurements without direct evidence of their actual chem. compn. On the basis of a thermodynamic study of the f.-p. lowering the actual compn. of  $\psi$  is shown to be Fe<sub>3</sub>Si<sub>2</sub>. Reasons why a solid soln. with a regular distribution should be treated as a compd. are also advanced. H. S. v. K.

X-ray study on alloys of silicon with chromium, manganese, cobalt and nickel. Bertil Borén. *Arkiv. Kemi, Mineral. Geol.* 11A, No. 10, 28 pp.(1933).—Four intermediate phases appear in the Cr-Si system. The first, Cr<sub>3</sub>Si, has cubic crystals with an edge of 4.555 Å. U. The second phase seems to be very complicated. It is not yet established but the structure appears to have a tetragonal form. It appears only at temps. below 1000°. The third phase, CrSi, is analogous to FeSi. The length of edge of the cube is 4.620 Å. U. The last intermediate phase, CrSi<sub>2</sub>, crystallizes hexagonally; the elementary prism contains 9 atoms and has the following dimensions:  $a = 4.422$  Å. U.,  $c = 6.351$  Å. U., and  $c/a = 1.44$ . In the Mn-Si system 3 intermediate forms appear, Mn<sub>3</sub>Si, MnSi and MnSi<sub>2</sub>. Mn<sub>3</sub>Si crystallizes hexagonally and has the following dimensions:  $a = 6.898$  Å. U.,  $c = 4.808$  Å. U., and  $c/a = 0.690$ . The elementary prism contains 16 atoms. The compd. MnSi has an FeSi structure with a cube edge of 4.548 Å. U. The last phase, MnSi<sub>2</sub>, belongs to the tetragonal system and has the following dimensions:  $a = 5.513$  Å. U.,  $c = 17.422$  Å. U., and  $c/a = 3.16$ . It is not analogous to FeSi<sub>2</sub>. The Co-Si system contains only 2 intermediate phases. The first, Co<sub>3</sub>Si, crystallizes in the rhombic system; the dimensions of the parallelepiped are:  $a = 3.710$  Å. U.,  $b = 4.908$  Å. U., and  $c = 7.095$  Å. U. The compd. CoSi has an FeSi structure with a cube edge of 4.438 Å. U. The Ni-Si system was only partially investigated; the presence of a compd. NiSi, analogous to FeSi, has been established. The edge of the elemental cube was estd. to be about 4.437 Å. U.

C. B. Jenni

The composition and action of metal cleaners. E. K. Strachen. *Metal Cleaning and Finishing* 5, 426-9(1933).—A practical discussion of the compn. and action of metal cleaners. General formulas are given. D. Thiessen  
The rusting of hot-water-heating plants. Alex. Marx. *Gesundh.-Ing.* 56, 481-3(1933).—A general discussion of the corrosive action of dissolved gases in both high- and low-pressure plants. Removal of gases from the feed water before use is recommended in the former case.

M. G. Moore

Protecting underground pipe lines against soil action. K. H. Logan. *Chem. & Met. Eng.* 40, 514-16(1933).—See C. A. 27, 5045. G. G.

The properties of bitumens and bitumen compounds of importance for use in protecting pipe lines against corrosion. J. Ph. Pfeiffer. *Hot Gas* 53, 413-23(1933).—A review of methods for detn. of penetration, ring and ball, m. p., Redwood viscosity, flowing tendency and brittleness of bitumens. Tabulated data and curves are given for typical examples. For use as pipe coating a zone of "asphalts" can be indicated on a diagram of penetration at 25° vs. m. p. in which sets of curves represent coal-tar pitch, "normal" asphalt and blown asphalt. For thin, 0.4 mm., dipped, bitumen coatings the material should have a penetration of less than 45 at 25°, less than 100 at 40°, a min. m. p. of 52°, a max. working temp. of 200°, max. brittleness by the Fraass method of 15°, by the Van Heurn and Begeyn fracture method of 40°. The coal-tar pitch type is generally best for this purpose. For enamel coatings (0.5-2.5 mm.) applied by brushing or centrifugation the brittleness is more important; blown asphalt

is advisable, with or without fillers. No flow should occur at 40° under a 45° angle. As to heavy, reinforced asphalt layers (interposed fibrous layers of hemp, jute, wool or asbestos) a detailed description is given of the application of Enamel HC of the Batavian Petroleum Co. for external and internal pipe protection. A coconut fiber reinforcement is used.

B. J. C. van der Hoeven

The corrosion problem. O. A. Knight. *Mineral Ind., Penna. State Coll.* 3, No. 1, 4(1933).—General.

Mechanism of corrosion of iron in sodium chloride solution—effect on the potential of the iron of adding organic substances to the brine. E. G. R. Ardagh, R. M. B. Roome and H. W. Owens. *Ind. Eng. Chem.* 25, 1116-21(1933).—A dependable procedure is described by which reproducible measurements of the potential of an Fe electrode in a brine can be obtained. This procedure is employed in making a survey of the inhibiting effect on the corrosion of Fe in brine of different classes of org. compds. Certain classes of org. compds. are shown to have a strong tendency to inhibit the corrosion of Fe in brine. The mechanism of this inhibiting action is partially elucidated.

M. E. Haas

Corrosion-time relationship of iron. R. F. Passano. *Ind. Eng. Chem.* 25, 1247-50(1933).—P. thinks that the use of calcd. rates of corrosion is likely to be misleading except when the corrosion-time relationship is linear or when one has a knowledge of the nature of the corrosion-time relationship existing under the particular conditions, whatever they may be. Various types of corrosion are presented graphically in their relationship to time. Eighteen references.

Alloys in the sugar factory (Rogers) 28. Corrosion in oil-cracking installation (Perry) 22. Corrosion from products of combustion (Anon.) 21. Attack of concrete-reinforcing Fe by blast-furnace cement (Erculisse) 20. Roasting ores (Ger. pat. 583,198) 20. Grinding in ball mills (Helm) 13.

Liddell, Donald M., and Doan, Gilbert E.: The Principles of Metallurgy. New York: McGraw-Hill Book Co., Inc. 626 pp. \$5.50.

Dressing barytes ore. Casper P. DeLore (to National Pigments & Chemical Co.). U. S. 1,930,709, Oct. 17. After crushing the ore it is further comminuted in the presence of water; heavier particles are settled out and these heavier particles are subjected to a hindered settling, particles of lighter sp. gr. than barytes are sep'd. from the particles and the residue is conveyed back to the comminuting app. App. is described.

Treatment of pyrites. Patentaktiebolaget Gröndal-Ramén. Ger. 583,380, Sept. 2, 1933. A mixt. of pyrites with a flux (if necessary) and a solid reducing agent is fused in a shaft furnace, the feed opening of which is sealed and into which air is blown from below. The amt. of reducing agent is adjusted so that SO<sub>2</sub> from the lower part of the charge is reduced in the upper part, the reducing agent being practically all consumed before the charge reaches the lower part of the furnace. The gases leaving the furnace then consist almost entirely of N, CO, and S, and after S has been condensed out the residual gases can

be safely discharged into the atm. When the ore contains Cu, the conditions may be adjusted so that not all of the S is driven off, the process then yielding a slag contg. FeO and SiO<sub>2</sub> and a concentrate contg. Fe, Cu and S. This concentrate is then roasted, and the SO<sub>2</sub> evolved is mixed with the air supplied to the shaft furnace. Numerous details are given.

Treatment of ores, etc., containing iron and sulfur. Comstock & Wescott, Inc. Ger. 583,049, Aug. 28, 1933. See Brit. 306,107 (C. A. 23, 4920).

Reducing sulfidic iron ores. Demag A.-G. Brit. 395,367, July 10, 1933. In smelting Fe ores having a high S content supplemental air is passed into the charge of ore, flux and coke, the vol. of such air being 30% or more of that required for the treatment of ordinary oxidic ores and being introduced at the point in the blast furnace where with such ores the reduction of the ore is complete. The extra air may be forced into the furnace through the ordinary tuyers or through tuyers disposed in 1 or more planes above these. The SO<sub>2</sub> produced in the lower part of the furnace is reduced by contact with solid C and CO to S which passes off with the waste gases from which it is sep'd. by gas washers, elec. filters or both filters.

Roasting sulfide ores, etc. Kenneth W. Young and Imperial Chemical Industries Ltd. Brit. 394,650, June 15, 1933. Sulfide ores, e. g., Zn blende, pyrites or partly burnt pyrites, particularly cuprous pyrites, or other S-contg. materials are roasted at 600-800° in the presence of a (preheated) gas contg. free O and at least 20% SO<sub>2</sub>, whereby non-ferrous metals are converted to sulfates. App. is described.

Treating titanium ores. Lonnie W. Ryan and Johan R. Knoff (to Titanium Pigment Co.). U. S. 1,929,521, Oct. 10. A Ti ore which is difficultly sol. in H<sub>2</sub>SO<sub>4</sub> such as rutile is heated with an alkali metal compd. such as NaHSO<sub>4</sub> or K<sub>2</sub>CO<sub>3</sub> in a quantity approx. corresponding to the chem. equiv. of the metallic elements required to convert the ore into acid-sol. alkali-metal titanate such as Na<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> or K<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>.

Apparatus for roasting zinc sulfide ore. Augustin L. J. Queneau. U. S. 1,929,713, Oct. 10. Various details are described of a furnace provided with an exterior sulfur burner for producing SO<sub>2</sub> which is conducted directly over the oxidized ore in the furnace.

Dead-roasting oxidized zinc sulfide ores. Augustin L. J. Queneau. U. S. 1,930,370, Oct. 10. An air-SO<sub>2</sub> mixt. heated to above the thermal decompn. temp. of metal sulfate compds. contained in the ores is circulated over them. App. is described.

Treating oxidized ores containing metals that have more than one valency. Ralph F. Meyer (to Meyer Mineral Separation Co.). Brit. 394,840, July 6, 1933. See U. S. 1,898,018 (C. A. 27, 2659).

System for cooling metallurgical furnaces, molds, etc., with water or steam circulated under high pressure. Ferdinand Heyd. Ger. 583,381, Sept. 2, 1933.

Crucible furnace suitable for melting metals. Furman South, Jr., and Oscar E. Neuhausen (to Lava Crucible Co.). U. S. 1,930,323, Oct. 10. Structural features.

Blast heater (Cowper type). Robert Kahlenberg. Ger. 583,208, Aug. 30, 1933.

Means for changing blast-furnace tuyères. Edgar E. Brosius. Ger. 584,146, Sept. 15, 1933. This corresponds to Brit. 381,634.

Recovering blast-furnace flue dust. Arthur B. Haswell and Frank G. Cutler. U. S. 1,930,010, Oct. 10. For sintering and fusing the finely divided material, it is forced into a zone heated at least sufficiently to incandesce the particles to a plastic stage, and the material is centrifugally projected upon a hearth maintained at a temp. sufficient to fuse the material. App. is described.

Flash-roasting apparatus. Eugene C. Clarke (to Bethlehem Foundry & Machine Co.). U. S. 1,929,308, Oct. 3. Various structural features are described.

Heat treatment of metals. Aluminium Ltd. Fr. 750,622, Aug. 14, 1933. Heat treatment of easily oxidizable metals, such as Al or its alloys, is carried out in an almost dry atm.

Furnace for heating metal billets. Heinrich Bangert. Ger. 583,059, Aug. 28, 1933.

Gas-heated furnace for heating ingots. Friedrich Siemens A.-G. Ger. 579,811, July 1, 1933. Addn. to 560,241 (C. A. 27, 940).

Converter for steel manufacture. Rudolf Frerich. Ger. 583,382, Sept. 2, 1933.

Treating drosses from melting metals. Frank F. Colcord and John J. Mulligan (to U. S. Smelting, Refining & Mining Co.). U. S. 1,931,285, Oct. 17. Drosses such as those formed in melting Pb, Zn, Sn, Bi, Cd and their alloys are subjected to prolonged agitation with the molten metals in the absence of refining agents until dry drosses of low entrained metal content are produced.

Porous metallic bodies such as bearings. Charles R. Short and Craig V. Morton (to Moraine Products Co.). U. S. 1,930,287, Oct. 10. Powd. materials such as Cu, Sn, Pb, graphite and salicylic acid are fed to a conveyor and carried progressively into position to be compressed, formed into a sheet and sintered. App. is described.

Drawing metals. Electro Metallurgical Co. Ger. 584,445, Sept. 20, 1933. The drawing of difficultly worked metals, e. g., Cr-Fe alloys, is facilitated by coating the metal with powd. Al and an adhesive, e. g., a gum or a cellulose ester or ether.

Oxidation resistant bimetallic material suitable for bimetal thermostatic devices. Howard Scott (to Westinghouse Elec. & Mfg. Co.). U. S. 1,929,055, Oct. 10. A high-expansion component contg. Fe together with Cr 5.7, Ni 22, Si 0.2 and Mn 0.7% and C about 0.47% is used with a low-expansion component contg. Fe together with Cr 17, Si and Mn each 1, C 0.1-0.45% and a trace of Ni.

Bright-annealing metal articles such as those of steel. Augustus B. Kinzel (to Electro Metallurgical Co.). U. S. 1,931,134, Oct. 17. The articles are heated to a suitable annealing temp. in a reduced atm. formed by heating with carbon a substantially dry gaseous atm. contg. at least 95% N associated with O-contg. gas.

Apparatus for polishing colored pulverulent bronze. Erwin Kramer (to Hartstoff-Metall A.-G.). U. S. 1,930,683, Oct. 17. Structural and mech. features. U. S. 1,930,684 also relates to app. and operative details of manuf. of "bronze colors."

Dyeing oxidized aluminum surfaces. Leon W. Eberlin (to Eastman Kodak Co.). U. S. 1,929,486, Oct. 10. In dyeing the oxidized coating produced on Al by electrolysis in an org. acid bath, the uniformity of the dyeing is controlled by adding to the dye bath an excess of CaCO<sub>3</sub> over that required to neutralize the acid carried in the oxidized coating.

Hardening aluminum. Robert S. Archer (to Aluminum Co. of America). U. S. 1,930,463, Oct. 17. Surface hardening of Al articles is effected by packing them in close and intimate contact with comminuted metallic Mg and heating to 250-460°.

Apparatus for comminuting lead and other soft metals. Stefan Weber. Ger. 584,453, Sept. 20, 1933.

Preventing oxidation of magnesium and its alloys. Edwin O. Barstow (to The Dow Chemical Co.). Brit. 395,633, July 20, 1933. See U. S. 1,898,909 (C. A. 27, 2668).

Zinc. Philip McL. Ginder, Willis McG. Peirce and Robert K. Waring (to The New Jersey Zinc Co.). Brit. 395,602, July 20, 1933. See Can. 333,962 (C. A. 27, 4765).

Joints between metal and siliceous refractories. Julius E. Lilienfeld. Brit. 394,311, June 6, 1933. A welded joint between Al and a siliceous refractory material, e. g., porcelain, is made by placing surfaces thereof in contact and heating until the Al begins to flow, an intermediate silicized layer being produced. The Al may constitute an elec. terminal or a suspension for an insulating base and the joint may be used in high voltage equipment, spark plugs, refrigerator seals, etc., as also in the electrode structure of electrolytic condensers.

Iron. Alfred Roemelt and Walter Nagel. Ger. 583,209, Aug. 30, 1933. App. is described in which powd.

Fe ore is blown into a hot gas stream produced by a pulverulent-fuel burner. Coal dust, fluxes, etc., may be mixed with the ore.

**Cast iron resistant to heat and shock.** Stanley W. Ewing and Harry A. Schwartz (to Link-Belt Co.). U. S. 1,931,109, Oct. 17. Malleable cast iron is subjected to successive heating and cooling to derive a structure contg. free carbon, ferrite and Fe carbide. The heating is carried above the crit. temp. but below the m. p. to cause the formation of Fe carbide, and the cooling is effected at a rate not less than about 5° per hr. to enable the retention of Fe carbide together with free C and ferrite.

**Apparatus for case-hardening iron.** Firma J. Aichelin. (Carl Hummel, inventor). Ger. 583,210, Aug. 30, 1933. Addn. to 509,206 (C. A. 25, 481).

**Coating iron or other metal surfaces, etc., with organic cellulose derivatives and synthetic resins.** Wm. H. Moss (to Celanese Corp. of America). U. S. 1,929,559, Oct. 10. A film of coating compn. is applied contg. both a cellulose org. deriv. such as cellulose acetate and a synthetic resin such as may be derived from phenol and formaldehyde, and an overlying coating is applied contg. a cellulose org. deriv. such as cellulose acetate without admixt. of synthetic resin.

**Nitrided ferrous articles.** Albert W. Morris (to Moore Drop Forging Co.). U. S. 1,929,252, Oct. 3. Ferrous articles have their surface impregnated to a depth of about 0.06 in. with a metal or alloy such as Al, Zr, Ti, Cr, V, Mg, Be, Si, Ni, Mo or Mn, having an affinity for N, and the surface is then hardened by nitridation.

**Hardening iron and steel.** Friedl. Krupp A.-G. (Otto Hengstenberg, inventor). Ger. 581,376, Sept. 19, 1933. Halogens or their compds. are used as accelerators in nitridation processes of hardening iron and steel.

**Refining iron and steel.** Paul Girod. Brit. 395,158, July 13, 1933. See Fr. 738,493 (C. A. 27, 1857).

**Rustless iron or steel.** Virginia Angelini. Brit. 394,806, July 6, 1933. To a bath of 500 kg. molten Fe or steel with the desired C content is added chromite (48% Cr<sub>2</sub>O<sub>3</sub>) 300, NiO 30, CaO 150, fluorspar 40 and bauxite 30 kg. and to this mass, when molten to form a slag, is added a reduction mixt. of metal oxides and reducing agents comprising chromite 820, NiO 110, Al 316 and Fe-Si 82 kg.

**Rust-proof iron or steel.** Walter Germann and Albert Strasser. Brit. 394,845, July 6, 1933. One to 20% of an alloy of equal proportions of Pb and As is added to a molten mass of Fe or steel which is alloyed with 3% Ti and 0.5-0.6% Mn.

**Cast steel die blocks, etc.** Karl V. Wheeler and LeRue P. Bensing (to Lebanon Steel Foundry). U. S. 1,929,909, Oct. 10. The blocks, etc., are formed by pouring molten steel into a mold formed of zircon sand.

**Forming and heat-treating steel rails.** John Brunner. U. S. 1,929,346, Oct. 3. A rail ingot or billet is subjected to rolling temp. above the thermal crit. range, rolled to a section larger than the desired finished section, cooled to below the thermal crit. range but above about 300°, reheated to just above the thermal crit. range, rolled to the desired finished section, again cooled to below the thermal crit. range but above 300°, and again heated to slightly above the thermal crit. range. The head of the rail is quenched at and near its ends until the surface temps. of the head at and near its ends lie within the blue-heat range but above about 200°, reheated to above 300° but below the thermal crit. range, and then slowly cooled to room temp. Cf. C. A. 27, 5298.

**Treating steel alloys, etc., in fused salt baths.** Vincent T. Malcolm (to Chapman Valve Mfg. Co.). U. S. 1,929,492, Oct. 3. Steel articles to be hardened are immersed in a fused salt bath including cyanide salts. A flow of NH<sub>3</sub> gas is subjected to the action of an ionizing elec. discharge to dissociate the gas into H and N and these gases are then passed into the bath immediately to supply free N. App. is described.

**Surface-hardening of alloy steels.** Wm. H. Hatfield (to Thos. Firth & John Brown Ltd.). U. S. 1,930,388, Oct. 10. See Brit. 377,244 (C. A. 27, 3187).

**Steel containing chromium, manganese and silicon.** Augustus B. Kinzel (to Electro Metallurgical Co.). U. S. 1,929,554, Oct. 10. A steel which has high ductility contains Cr 0.2-0.75, Mn 0.6-2.5, Si 0.2-2.5 and C less than 0.1%.

**Treating molten steel with sodium vapor.** Harvey N. Gilbert (to E. I. du Pont de Nemours & Co.). U. S. 1,931,144, Oct. 17. N is passed through molten Na maintained at about 750-850°, and the resulting mixt. of N and Na vapor is passed into a body of molten steel in order to effect its purification. App. is described.

**Cobalt magnet steel.** Adolph F. Bandur and Herbert M. E. Heinicke (to Western Elec. Co.). U. S. 1,930,919, Oct. 17. In order to improve its magnetic properties, the magnet steel is heated to a rolling temp. of about 1150° and the cross-sectional area of the steel is reduced; then it is reheated, before it cools, substantially to maintain the rolling temp., and its cross-sectional area is again reduced, this being followed by reheating to 930° and quenching.

**Treating austenitic steel.** Emanuel J. Janitzky. U. S. 1,929,356, Oct. 3. Rails and shapes of austenitic Mn steel are subjected, at a cold-working temp., to alternate internal compressive and tensile stresses of an intensity at least beyond the elastic limit of the steel. These stresses are applied to the rail or the like progressively along its length and along a plane substantially transverse to its length (suitably by the action of staggered rolls) and serve to increase the elastic limit and wear resistance.

**Alloys.** Heraeus-Vacuumschmelze A.-G. and Wilhelm Rohn. Brit. 395,060, July 13, 1933. See Fr. 730,718 (C. A. 27, 262).

**Alloys.** N. V. Molybdenum Co. Brit. 395,719, July 17, 1933. Divided on 395,721. Shaped articles, e. g., tools or tool parts, are made by mixing 1 or more carbides of 1 or more metals of the 4th and 6th groups, particularly Si, Ti, Zr, W and Mo, with 1 or more auxiliary metals of the 6th and 8th groups, particularly Cr, Mo, W, Fe, Co and Ni, preliminarily shaping the mixt., heating it for about 1-15 min. at over 1100°, interrupting the heating, finally shaping by mech. treatment and continuing the heating for 1 or more hrs. Examples of compns. are:

(1) Mo carbide, Ti carbide, Ni and Cr, (2) Ti carbide, Ni and Cr, (3) W carbide and Co and (4) W carbide and W, the Mo carbide and Ti carbide being in each case replaceable by Zr carbide. In 395,721, July 17, 1933, alloys consist of 21-50% of 1 or more carbides of the 6th group, particularly Cr, Mo and W, up to 22% of 1 or more auxiliary metals of the 6th and 8th groups, particularly Ni, Co and Cr, and 1 or more carbides of 1 or more 4th group elements, particularly Ti, Si and Zr, as remainder. Up to 2% of oxides of alk. earth metals, Al and Si may be added. The Mo carbide may be made by heating in a reducing atm. to 1400-1600° a powd. mixt. of Mo and C in the proportions to produce Mo<sub>2</sub>C. Ti carbide may be similarly made at a higher temp. or by treating a mixt. of TiO<sub>2</sub> and C, the product being again heated with C to remove residual O. Zr carbide and Si carbide may be similarly produced. Alternatively, gases, e. g., coal gas, may be passed over heated powd. metal or compds. thereof in C tubes. In 395,735, July 17, 1933, divided on 395,721, shaped articles are made by mixing 1 or more carbides of 1 or more metals of the 4th and 6th groups with 1 or more auxiliary metals of the Fe group, with or without a metal or metals of the 8th group, adding glycerol or glycols, preliminarily shaping the mixt., allowing it to dry or harden, expelling at about 100-200°, if necessary, any excess reagent, finally shaping the article by mech. treatment and heating at over 1100°.

**Alloys.** Alfred Ricard. Ger. 584,020, Sept. 13, 1933. Alloys for making bearings contain Cu 52-68, Pb 23-38, Si 2-4, Ni 5-8 and Fe 0.5-1.5%. The alloys may be prep. by adding Pb to an alloy of Cu, Si, Ni and Fe heated to 1150°, oxidation of the Pb being avoided by covering the surface of the alloy with glass, wood charcoal, SiO<sub>2</sub>, etc.

**Alloys for golding and brazing.** Handy & Harman.

Ger. 584,172, Sept. 15, 1933. The alloys contain Cu 67-88, Ag 10-25, and P 2-8%. Specific alloys are described.

**Improving alloys.** Vereinigte Deutsche Metallwerke A.-G. Zweigniederlassung Basse & Selve. Brit. 395,720, July 21, 1933. Alloys consisting of Cu, Ni and a metal or metals of the group, Fe, Cr, Mo, Co, Mn, V or W, and having a compn. lying outside the range of miscibility in the solid state at ordinary temps. but within said range at temps. approaching the m. p. are improved by homogenizing the cast alloys by heating to between 800° and the m. p. and are subsequently either worked mechanically at the homogenizing temp. or are chilled and then so worked in the cold state. After working at the homogenizing temp. the alloys may be quenched and then tempered at 300-800°. The cold worked alloys may also be tempered at 300-800°.

**Sintered alloys.** Floyd C. Kelley (to The British Thomson-Houston Co. Ltd.). Brit. 395,064, July 13, 1933. A sintered alloy consists of Ta carbide and a metal binder consisting substantially of Co and W, the Ta carbide being in excess of the binder. Powd. Ta carbide, prep'd. according to Brit. 388,000 (C. A. 27, 4761), W and Co are pressed and sintered at 1300-1600°. The alloy may be used for tool tips or bits, being Cu brazed to a steel shank.

**Alloy for torsion-springs of clocks, watches, etc.** Thomas H. Chamberlain (to New Haven Clock Co.). U. S. 1,931,251, Oct. 17. A torsion spring combining high elastic limit, ductility and a substantially uniform modulus of elasticity is formed of an alloy contg. Fe together with Ni 34.5-37.5, Cr 11-13, Mn 0.6-1.0, Si 0.25-0.9 and C 0.07-0.35%.

**Alloy suitable for cast dentures.** Robert R. Bayes (to Baker & Co.). U. S. 1,930,119, Oct. 10. The alloy consists of Au 10-20, Pd 20-30, Ag 40-50, Cu 11-18 and Zn 1-4%.

**Aluminum alloys.** Wm. S. Kellar (to Electrical Research Products, Inc.). Brit. 391,380, June 26, 1933. A vibratory element, e. g., a microphone transmitter diaphragm of a light valve ribbon, is produced from an Al alloy contg. Cu 3.15-4.50, Si 0.20-0.50, Mg 0.40-1.00, Mn 0.40-1.00 and Fe not more than 0.50%. The alloy is reduced to strip form, maintained at 930-960°F. for 30-45 min., quenched, cold-rolled to about 0.0017 in. thickness, seasoned by being heated to about 212°F. for about 40 hrs. and then formed into the desired product.

**Aluminum alloys.** Aluminium Ltd. Brit. 395,586, July 20, 1933. See Fr. 748,612 (C. A. 27, 5302).

**Working aluminum base alloys.** Aluminium Ltd. Brit. 395,273, July 13, 1933. Ingots of Al base alloys contg. 5-15% Mg are preheated at above 550°F. but below the temp. of incipient fusion of the most fusible constituent and rapidly cooled to a working range between 475-600°F. The ingot may be reheated and cooled 1 or more times during working.

**Aluminum alloys containing manganese and magnesium.** Theodore W. Bossert (to Aluminum Co. of America). U. S. 1,928,641, Oct. 3. Alloys which give smooth-drawn products contain Al together with Mn about 0.75-3.0% and Mg about 0.2-0.5%.

**Aluminum-silicon alloys.** Lightalloys Ltd. and Wm. H. Grieve. Brit. 394,746, July 6, 1933. Al-Si alloys contg. 7-15% Si also contain up to 5%, preferably less than 1%, Mg, with or without up to a total of 1% of Mn, Cr, Ni, Cu, W, Ti, Mo and (or) V, there being no intentional addn. of Cu or Ca. The alloys may be heat-treated by heating at 140-185° for up to 24 hrs.; this may be preceded by heating at 500-520° for about 4 hrs. and quenching in cold H<sub>2</sub>O.

**Acid-resisting copper base alloys suitable for tanks, boilers, pipes, etc.** Reginald Hazlting. U. S. 1,930,956, Oct. 17. Cu is alloyed with Si 1.5-5.0 and Cr 0.1-1.0%.

**Ferrous alloys.** Wm. H. Seaman. Brit. 395,121, July 13, 1933. Chilled Fe rolls are made by casting in chill molds Fe alloys contg. C 2.6-3.85, Ni 2.5-5, Si 0.15-0.65 and Mn 0.15-0.27% with an amt. of Cr not exceeding one-tenth of the Ni content. In some cases the alloys may contain also 0.15-0.5% Mo, when they may contain Ni 1.25-5 and Si 0.2-1%. Cf. C. A. 27, 1319.

**Iron alloys.** Rudolf Bellak. Brit. 394,346, June 16, 1933. Fe alloys contain W 0.5-15, Co 1.2-5, Ni 1-5 and C 0.1-0.5%, with or without small quantities of Mo, V, Ta, Ti, Zr, Si, Mn, Cu and Al. Cr not exceeding 2% may be present. They are readily worked after quenching in oil or air, maintain their hardness when heated to 500-600° and are particularly suitable for tools working in heat, tools in presses, valve cones and blades of turbines, gun-barrels, etc.

**Magnesium alloys.** John A. Gann and Frid L. Reynolds (to The Dow Chemical Co.). Brit. 394,551, June 20, 1933. See U. S. 1,885,429 (C. A. 27, 946).

**Nickel alloys.** International Nickel Co., Inc. Brit. 394,378, June 23, 1933. Alloys contg. 2-99% Ni and having a lattice structure of the face-centered cubic type are hardened by including 1-10% Ti therein and holding them at 1 or more temps. in excess of 600° but not exceeding 800°. The alloys may include alloys of Ni with Cu, Fe, Mn and Cr in various combinations and may contain small amts. of Al, Si, C and other elements usually present in Fe and steel. The hardening process may be applied to so-called marginal austenitic steels.

**Zinc alloys.** Joseph Sennec. Brit. 395,271, July 13, 1933. Divided on and addn. to 388,221. A mandrel forming part of a machine for grinding round holes is made of an alloy contg. Zn, Al and Cu. A suitable alloy consists of Zn 93.5, Al 4, Cu 2 and Mg 0.5%.

**Zinc-base die-casting alloy.** John R. Freeman, Jr. (to American Brass Co.). U. S. 1,930,341, Oct. 10. Zn of 99.98% or higher purity is alloyed with Cu 0.5-15%, forming alloys free from "hot shortness." Cf. C. A. 27, 5712.

**Coating metals.** Verein für die Probier- und Forschungsanstalt für Edelmetalle. Brit. 395,491, July 20, 1933. An invisible protective coating is formed on the surface of Ag (alloys) by treating with a soln. contg. CrO<sub>3</sub>. Cuprammonium chloride, a persulfate or both may be added. The metal is preferably first degreased and then immersed in the soln., washed and dried.

**Apparatus for coating wire.** Johnson Steel & Wire Co., Inc. Ger. 583,393, Sept. 2, 1933. This corresponds to Brit. 370,626 (C. A. 27, 2664).

**Coating aluminum or its alloys.** Siemens & Halske A.-G. (Nicolai Budiloff and Alexander Jenny, inventors). Ger. 583,023, Aug. 26, 1933. Noble-metal coatings are produced on Al or its alloys by superficially oxidizing the Al or alloy in known manner, and applying to the oxidized surface a solid or dissolved noble-metal compd., e. g., AgNO<sub>3</sub>, which is then decomposed by heat. A reducing agent which leaves no residue, e. g., sugar or alc., may be applied with the metal compd.

**Tin plating.** The Roessler & Hasslacher Chemical Co. Brit. 395,377, July 14, 1933. In the use of Sn-plating baths contg. 0.25-0.65 mole of alkali stannate per l. and 1.6 moles of caustic alkali per mole of stannate plus an addnl. amt. of caustic alkali of 0.2-0.4 mole per l. the alkali content is corrected when it has become too high by addn. of (a preferably weak) acid, e. g., AcOH, and, at approx. the same time, an oxidizing agent, e. g., H<sub>2</sub>O<sub>2</sub>, alkali metal peroxide, permanganate, persulfate or perborate. Thymol phthalein is preferably used as indicator in the detn. of the caustic alkali which includes that set free by hydrolysis of the stannate. The plating temp. is preferably 60-80° and the current d. 10-100 amps. per sq. ft. at the cathode and up to 20 amps. per sq. ft. at the anode.

**Plated zinc sheets.** Franz Jordan. Brit. 395,585, July 20, 1933. A Zn alloy contg. 98-99% Zn and 2-1% Al is used for producing compd. sheets of Al and the alloy. The Al sheet is rolled onto the Zn alloy sheet while white-hot, heated to a higher temp. than that of the Zn alloy sheet, both temps. being within the limits 180-450°. The plated sheet may be rolled out into metal foil. The Al sheet may be made of an Al-Ag alloy. The sheets may be plated on 1 or both sides and after plating may be heated to 150-300°.

**Protecting iron against rust.** N. V. Maatschappij tot

exploitatie van de Parker Octrooien "Parker Rust Proof." Ger. 583,349, Sept. 1, 1933. Fe articles, after treatment in known manner in a phosphate bath contg. a compd. of a less electropos. metal, e. g., Cu, are treated with a chromate soln. or with a soln. contg. 1-3 g. of free  $\text{CrO}_3$  per l.

Protecting iron and steel against corrosion. Aladar Pacz. Ger. 584,411, Sept. 20, 1933. A resistant coating is produced on articles of iron and steel by treating them for a short time, e. g., 15 min., preferably at a raised temp., with a dil. bath contg.  $\text{H}_2\text{PO}_4$  (or a primary phosphate of a heavy metal) and a sol. compd. of  $\text{MoO}_3$ , e. g.,  $\text{NH}_4$  molybdate. The bath may also contain an acid fluoride or other salt capable of liberating  $\text{MoO}_3$  from the sol. Mo compd.

Protecting lead against corrosion. Comp. générale d'électricité. Ger. 584,124, Sept. 15, 1933. See Fr. 716,148 (C. A. 26, 1892).

Arc welding. Elektriska Svetnings Aktiebolaget and Per Y. Sjöman. Brit. 395,510, July 20, 1933. In elec.-arc welding cast or other Fe, alloyed steel or non-ferrous metals a fusible metal electrode is provided with a flux contg. more than 50% of a non-oxidizing metallurgic or synthetic slag of the same kind as that obtained in the manuf. of the electrode metal. The slag may be applied wholly or partly as an external coating on the electrode or to the interstices of a wire wound thereon. Examples of coating for steel electrodes are: (1) acid Bessemer or Siemens-Martin slag 82, Fe-Mn 8 and Na waterglass 10% and (2) basic Siemens-Martin slag 57, cellulose 25, Fe-Mn 8 and dextrin 10%. For cast Fe electrodes the coating may contain blast furnace slag 53, graphite 25, Fe-Si 10 and Na waterglass 12%.

Arc welding. Adalbert Alexay (to The British Thomson-Houston Co. Ltd.). Brit. 395,663, July 20, 1933. In arc welding the arc and molten portions of the weld are surrounded by an enveloping mist of an atomized liquid, e. g., a hydrocarbon, MeOH or other alc. App. is described.

Arc welding. James M. Weed (to The British Thomson-Houston Co. Ltd.). Brit. 395,967, July 27, 1933. A flux for arc welding, which may be inserted as a core or in pockets in a metal electrode or applied as a coating thereto, contains feldspar, a binder, e. g., liquid Na silicate, and talc and (or)  $\text{TiO}_2$ . The flux preferably consists of  $\text{TiO}_2$  0-1, talc 0-1, K feldspar 1 part and Na silicate equal to the combined wts. of the other ingredients. Al, Zn, V, Ti, Si, Mn, etc., may be added to the paste for protecting the molten metal from O and N.

Apparatus for welding together sections of zinc wire to form continuous lengths. Leaman S. Harvey and Howard P. Hart (to Platt Bros. & Co.). U. S. 1,931,001, Oct. 17. Various mech. and operative details are described.

Arc-welding electrode. Clifford B. Langstroth and Edwin M. Martin. U. S. 1,930,649, Oct. 17. A metallic core is coated with a shredded carbohydrate material such as shredded wood and various assocd. materials such as Na silicate,  $\text{CaCO}_3$ , and silico-Mn.

Arc-welding electrode. Robert Notvest (to J. D. Adams Mfg. Co.). U. S. 1,931,406, Oct. 17. A ferrous rod is coated with fluxing material together with a coumarone resin.

Welding electrodes. David L. Mathias (to Westinghouse Elec. & Mfg. Co.). U. S. 1,930,530, Oct. 17. For producing electrodes contg. occluded H, the electrodes are pickled in an acid bath contg. an inhibitor and the acid is removed; the electrodes are coated with a lubricant and drawn through dies to harden them, and are then treated with a second acid bath which is of sufficient strength and employed for a sufficient time to cause a substantial amount of H to be occluded in the electrode rods. Acid is then removed by washing with water.

Welding rods. Theophil E. Jerabek (to The Lincoln Electric Co.). Brit. 395,228, July 13, 1933. A slag-forming compn. in the form of an adherent coating for welding rods includes  $\text{TiO}_2$  and a silicate of Mg and (or) Fe. The coating may contain  $\text{TiO}_2$  and at least 1 of the following: Mg silicate, Fe silicate, talc, chrysotile, chrysotile, amosite, crocidolite, anthrophyllite, tremolite, actinolite.

Arc-welding fluxes. Lucian B. Thompson and Verni J. Chapman (to The British Thomson-Houston Co. Ltd.). Brit. 394,610, June 29, 1933. A flux for arc welding contains Fe-Mn, talc, feldspar and liquid Na silicate. The mixt. preferably consists of Fe-Mn of C content less than 1.5% 10, talc 10, feldspar 30 and Na silicate of sp. gr. 1.36 24 parts. It may also contain cellulosic material, e. g., cotton yarn, cloth or gauze or braid.

Welding fluxes. Murex Welding Processes Ltd., Aubrey T. Roberts and John H. Paterson. Brit. 394,319, June 9, 1933. A flux compn. for use in the elec. welding of ferrous metals includes Fe in powd., granular or other form offering an extended surface whereby the Fe preferentially reacts with the atm. constituents in the neighborhood of the weld metal, the compn. being free from any substance, e. g., salts, that decomposes at a red heat with disengagement of O. The finely divided Fe is at least 15% of the core metal, and small proportions of other metals, e. g., Mn, Ti, V or Si, may be added to the Fe, preferably as ferro alloys. China clay or colloidal  $\text{SiO}_2$  may be added to the compn.

Soldering flux. Frank D. McBride (to Berry Solder Co.). U. S. 1,929,895, Oct. 10.  $(\text{CH}_3)_2\text{N}_4$  1-25% is used together with a monohydric alc. ester of abietic acid such as ethyl or methyl abietate.

## 10—ORGANIC CHEMISTRY

CHAS. A. ROULLER AND CLARENCE J. WEST

Applications of the Raman effect to organic chemistry. Maurice Bourguet. *Bull. soc. chim.* 53, 409 505(1933).—A rather complete, well-written account of the applications of the Raman effect as a research method in org. chemistry. Numerous references are given.

Raman effect and chemistry. Study of several  $\alpha$ -ethylene oxides. R. Lespiau and R. Gredy. *Bull. soc. chim.* 53, 769-82(1933).—See C. A. 27, 2678. G. G.

The constitution of molecular compounds. Priyadarajan Ray. *J. Indian Chem. Soc., Prafulla Chandra Ray Commemoration Vol.* 1933, 161-9.—After a crit. examn. of the different views regarding the structure of mol. compds., R. suggests a probable solution of the problem.

The utilization of methane. T. S. Wheeler. *J. Indian Chem. Soc., Prafulla Chandra Ray Commemoration Vol.* 1933, 53-60.—Expts. were carried out to det. possible methods of utilizing  $\text{CH}_4$  for the production of HCN,

$\text{CS}_2$  and aromatic hydrocarbons. Chlorination of  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{MeCl}$ ,  $\text{C}_2\text{H}_5$  and PhMe in the gaseous phase was studied. High temp. and high space velocity were employed.

Polymerization and explosive decomposition of ethylene under pressure. Gustav Egloff and R. E. Schaad. *J. Inst. Petroleum Tech.* 19, 800-11(1933).— $\text{C}_2\text{H}_4$  was polymerized to a brown or reddish oil either in an autoclave or in passing through a heated steel tube, and in the presence or absence of  $\text{Al}_2\text{O}_3$ . At  $380^\circ$  in the autoclave and 80 atm. initial pressure the yields of oil were 63-73% of the wt. of  $\text{C}_2\text{H}_4$  charged. A temp. of  $480^\circ$  was necessary in the steel tube to obtain the same yields. When the mixed catalyst  $4\text{NiO} \cdot \text{Al}_2\text{O}_3 \cdot \text{CuO}$  was used the  $\text{C}_2\text{H}_4$  exploded at  $330^\circ$ .

Preparation and reactions of 4,4-dimethyl-1-pentene (neopentylethylene). Frank C. Whitmore and August H. Homeyer. *J. Am. Chem. Soc.* 55, 4555-9(1933).—

$\text{CH}_3\text{CHCH}_2\text{CH}_2\text{CH}_3$  and *tert*-BuMgCl give about 85% of

**4,4-dimethyl-1-pentene (I)**,  $b_{760}$  72.35°,  $d_4^{20}$  0.6827,  $n_D^{20}$  1.3911; the dibromide (1,2-dibromo-4,4-dimethylpentane),  $b_{760}$  77-8°,  $d_4^{20}$  1.5129,  $n_D^{20}$  1.4970; addn. of HBr gives 1-bromo-4,4-dimethylpentane (II),  $b_{760}$  70-1°,  $b_{760}$  154°,  $d_4^{20}$  1.1343,  $n_D^{20}$  1.4484. I does not add H<sub>2</sub>. II forms a Grignard reagent which reacts with HgBr<sub>2</sub> to give 1-bromomercuri-4,4-dimethylpentane, m. 101°, and with O<sub>2</sub> to give 90% of 4,4-dimethylpentan-1-ol,  $b_{760}$  96°,  $b_{760}$  158°,  $d_4^{20}$  0.815,  $n_D^{20}$  1.4202 ( $\alpha$ -naphthylurethan, m. 80.5-1°). I reacts with AcOH in the presence of H<sub>2</sub>SO<sub>4</sub> to give the acetate of 4,4-dimethylpentan-2-ol and a mixt. of olefins. I and 85% H<sub>2</sub>SO<sub>4</sub> give a mixt. of polymers  $b_{760}$  59-122°.

C. J. West

**Acetylene polymers and their derivatives.** XVII. **Mercury derivatives of vinylacetylene.** Wallace H. Carothers, Ralph A. Jacobson and Gerard J. Berchet. *J. Am. Chem. Soc.* 55, 4065-7 (1933); cf. *C. A.* 27, 3911.—CH<sub>2</sub>:CHC≡CH and alk. HgI<sub>2</sub> or HgO in AcOH give divinylethynylmercury, m. 114-5°; on standing 48 hrs. it becomes yellow and insol. in CHCl<sub>3</sub> and explodes under the action of heat or mech. shock; it reacts with Ba or I to give the corresponding bromo- or iodo vinylacetylene. If the temp. of the reaction with HgO is raised to 60-70° there results 93.4% of 1,1-diacyloxymercuri-2-acyloxymercurioxy-1,3-butadiene (I); KI in AcOH gives 1,1-diiodomercuri-2-iodomercurioxy-1,3-butadiene, pale yellow; KBr and KCl give the corresponding Br and Cl derivs. Hydrolysis of I gives Mt vinyl ketone, Br and I in CHCl<sub>3</sub> give CH<sub>3</sub>:CHCOBr. XVIII. **1-Halogen-2-vinylacetylenes.** R. A. Jacobson and W. H. Carothers. *Ibid.* 4607 9.—CH<sub>2</sub>:CHC≡CH and KOBr give 55% 1-bromo-2-vinylacetylene,  $b_{760}$  52-3°,  $d_4^{20}$  1.4804,  $n_D^{20}$  1.5182; it did not polymerize when stabilized with hydroquinone; after several months it was a highly explosive black solid. The 1-I deriv.  $b_{760}$  78°,  $d_4^{20}$  1.4908,  $n_D^{20}$  1.5948 (27.5% yield); after 1 month at 10° it polymerizes to a jelly and after several months it was a black solid like charcoal and extremely explosive. 1-Cl deriv.,  $b_{760}$  55-7°,  $d_4^{20}$  1.0032,  $n_D^{20}$  1.4063. HCl and the 1-I deriv. in the presence of NH<sub>4</sub>Cl and CuCl give C<sub>4</sub>H<sub>4</sub>Cl<sub>2</sub>,  $b_{760}$  73.5-4.5°,  $d_4^{20}$  1.9161,  $n_D^{20}$  1.6073, which forms a soft black tar on standing.

C. J. West

**Homogeneous thermal polymerization of isoprene.** Wm. B. Vaughan. *J. Am. Chem. Soc.* 55, 4109-16 (1933). 6  
-The homogeneous thermal polymerization of isoprene was investigated in the temp. range 286.5-371° at pressures ranging from 212 to 739 mm.; the principal process is interpreted as a bimol. assocn. reaction, the rate of which is expressible by  $k = 2.19 \times 10^{10} T^{-2.1} e^{-23,900/RT}$ .

William B. Vaughan

**Chlorinated paraffin. I. Relation of chlorine content to physical properties.** F. T. Gardner. *Ind. Eng. Chem.* 25, 1211-12 (1933). -Samples of com. paraffin were chlorinated at 70°. The final Cl content varied between 20 and 48.5%. The viscosity rises sharply after a Cl content of 40% has been reached. I.-p. data indicate slight if any polymerization.

W. A. Moore

**Higher aliphatic compounds. V. Systems with heptadecyl alcohol and heptadecane. Polymorphism of octadecane.** Peggy C. Carey and J. C. Smith. *J. Chem. Soc.* 1933, 1348-51; cf. *C. A.* 27, 4526.—Heptadecyl alc. (I) has the const. f. p. 53.80°, m. p. 53.83°; m.-p. curves are given for I with hexadecyl alc. and with octadecyl alc. In each system there is a min. which is slightly below the f. p. of the lower alc. Heptadecyl iodide has f. p. 34.05°, m. p. 34.13°. Heptadecane (II) has f. p. 21.92°, m. p. 21.97°; it seps. in transparent plates which change reversibly into the opaque form of lower m. p. All specimens of octadecane (III) show a m. p. of 27.9-28.0° but may be cooled to as low as 27.4°; transparent crystals then suddenly appear, the temp. rising usually only 0.1°; heating gives a m. p. 27.9-28.0° in each case and the crystals become opaque. F.-p. curves are given for II-III and II-hexadecane (IV). As the dominant form is the transparent  $\alpha$ -crystal common to both even and odd hydrocarbons, the systems differ little from that of IV-III. Near the extreme compns. IV and (more slowly) III undergo monotropic change to the  $\beta$ -forms. C. J. W.

**The trimethylene trisulfide of melting point 247°.** O. Hinsberg. *J. prakt. Chem.* 138, 214 (1933).—Polymical with Chattaway and Kellett (*C. A.* 25, 3650).

C. J. West

**$\gamma$ -Trimethylene trisulfide perchlorate.** O. Hinsberg. *J. prakt. Chem.* 138, 207-13 (1933).— $\gamma$ -Trimethylene trisulfide, m. 216°, yields a perchlorate (I), decomps. 138° (32% yield); the picrate, yellow, decomps. 134°. I and H<sub>2</sub>O<sub>2</sub> in AcOH and Ac<sub>2</sub>O give CH<sub>3</sub>SO<sub>3</sub>CH<sub>2</sub>SO<sub>3</sub>CH<sub>3</sub>.

CH<sub>3</sub>SO<sub>3</sub>CH<sub>2</sub>SO<sub>3</sub>CH<sub>3</sub>. I and AcONa in AcOH-Ag<sub>2</sub>O, boiled 6 min., give diacetyldimercapto dimethyl sulfide, m. 37°. MeOH-KOH and I give a compd. m. 93° and one m. 50°.

C. J. West

**Plato- and pallado-sulfines.** H. D. K. Crew, G. H. Preston, W. Wardlaw and G. H. Wyatt. *J. Chem. Soc.* 1933, 1204 6.—At low temps. and especially in dil. soln. C<sub>2</sub>H<sub>4</sub>(SET)<sub>2</sub> and K<sub>2</sub>PtCl<sub>4</sub> give the pink plato-salt, [Pt es<sub>2</sub>]PtCl<sub>4</sub> (es is C<sub>2</sub>H<sub>4</sub>(SET)<sub>2</sub>); at 100° and in more concd. solns. the yellow disulfine, [Pt es Cl<sub>2</sub>], is largely produced; the disulfine, lemon-yellow triboelectric plates or needles, m. 185°; with cold aq. Ag<sub>2</sub>O it gives a base, yellow glass, whose alk. soln. gives with HCl the original disulfine [Pt es<sub>2</sub>]PtCl<sub>4</sub> m. about 180° but transformation into [Pt es Cl<sub>2</sub>] has already occurred. The plato-salt gives Magnus' salt with hot aq. [Pt(NH<sub>3</sub>)<sub>4</sub>]Cl<sub>2</sub>. C<sub>2</sub>H<sub>4</sub>(SET)<sub>2</sub> and K<sub>2</sub>PdCl<sub>4</sub> at room temp. apparently give only [Pd es Cl<sub>2</sub>], yellow, m. 182°. Pd(SET)<sub>2</sub>Cl<sub>2</sub> m. 83°, is unimol. in free/mg C<sub>2</sub>H<sub>4</sub> or boiling CHCl<sub>3</sub>; it is sol. in aq. Et<sub>3</sub>S, giving a soln. of the unstable [Pd(SET)<sub>2</sub>]Cl<sub>2</sub>, which loses Et<sub>3</sub>S in the air. Pd(SMe<sub>2</sub>)<sub>2</sub>Cl<sub>2</sub> m. 128°. The soly. of [Pt es Cl<sub>2</sub>] at 25° is 0.130 g. per 100 cc. H<sub>2</sub>O; at this diln (319 l. per g.-mol.) the value of  $\mu = 28$  was found; if  $\mu_{\infty} = 100$ , the ionization is about 30% at  $v = 319$ . Acetonebis(Et thioacetate) and K<sub>2</sub>PtCl<sub>4</sub> do not form a plato-salt; the yellow to orange cryst. ppt. has no definite m. p. and is of varying compn. Et<sub>3</sub>S<sub>2</sub> behaves similarly.

C. J. West

**Dielectric polarization. VIII. The dipole moments of alkyl nitrates and nitrites.** Eric G. Cowley and James R. Partington. *J. Chem. Soc.* 1933, 1252-4; cf. *C. A.* 27, 2671. -The following figures give the b. p.,  $d_4^{20}$ ,  $n_D^{20}$  and dipole moment ( $\mu$ ): MeNO<sub>2</sub>,  $b_{760}$  65°, 1.2075, 1.3748, 2.85; EtNO<sub>2</sub>,  $b_{760}$  87.2°, 1.1084, 1.3852, 2.91; PrNO<sub>2</sub>,  $b_{760}$  110.4°, 1.0548, 1.3979, 2.98; BuNO<sub>2</sub>,  $b_{760}$  135.7°, 1.0153, 1.4063, 2.96; EtNO<sub>2</sub>,  $b_{760}$  17°,  $d_4^{20}$  0.9065,  $n_D^{20}$  1.3418, 2.20; PrNO<sub>2</sub>,  $b_{760}$  48.9-9.4°, 0.8861, 1.3604, 2.28. By assuming an O valency angle of 90° and the moment of the MeO group as 0.81 the NO<sub>2</sub> group moment is found to be 2.73. The results are contrasted with those of the NO<sub>2</sub> compds., in which induction along the hydrocarbon chain occurs. IX. The dipole moments of some nitrosoamines, *p*-nitrosophenol, ethylaniline, hydrazobenzene and benzaldehyde phenylhydrazones. *Ibid.* 1255-7.—Me<sub>2</sub>NNO,  $b_{760}$  154°,  $d_4^{20}$  1.0061,  $n_D^{20}$  1.4368,  $\mu$  3.28; Ph<sub>2</sub>NNO, m. 66.5°,  $\mu$  3.39; PhMe<sub>2</sub>NNO, m. 14.7°,  $d_4^{20}$  1.1288,  $n_D^{20}$  1.5709,  $\mu$  3.62; PhEt<sub>2</sub>NNO,  $d_4^{20}$  1.0874,  $n_D^{20}$  1.5598,  $\mu$  3.61; ONC<sub>6</sub>H<sub>4</sub>OH, m. 126°,  $\mu$  4.72; PhEt<sub>2</sub>NNH<sub>2</sub>, m. 1.68; (PhNH)<sub>2</sub>, m. 127°,  $\mu$  1.66; PhCH<sub>2</sub>NNHPh, m. 156°,  $\mu$  1.89. The moments of the hydrazo compds. are discussed. X. The dipole moments of the nitroanisoles. *Ibid.* 1257-9.—*o*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OMe, f. p. 10.3°,  $d_4^{20}$  1.2408,  $n_D^{20}$  1.5597,  $\mu$  4.83; *m*-isomer, m. 35.7°,  $\mu$  3.86; *p*-isomer, m. 52°,  $\mu$  4.74. The results are discussed in relation to the O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OH. XI. The dipole moment of pyrrole. *Ibid.* 1259.—Pyrrole,  $d_4^{20}$  0.9600,  $n_D^{20}$  1.5208,  $\mu$  1.83. This value is lower than that of pyridine and quinoline (2.11 and 2.18, resp.).

C. J. West

**The Raman effect with tetranitromethane.** M. Milone. *Gazz. chim. ital.* 63, 453-6 (1933).—Contrary to evidence obtained by chem. and phys.-chem. means by various authors, a study of the Raman effect indicates that the formulas of tetranitromethane, chloropicrin and bromopicrin are C(NO<sub>2</sub>)<sub>4</sub>, CCl<sub>3</sub>(NO<sub>2</sub>) and CBr<sub>3</sub>(NO<sub>2</sub>), resp., i. e., true nitro derivs.

C. C. Davis

The Raman spectra of some heterocyclic compounds. II. M. Milone. *Gazz. chim. ital.* 63, 456-63(1933); cf. C. A. 27, 5003 and preceding abstr.—The expts. were continued with 7 other isomeric and non-isomeric furazans, azoximes and oxadiazoles, the phys. consts. of which in purified form were found to be as follows:

$\text{PhC:N.O.N:CPh}$ , m. 98°,  $b_{10}$  202° (cf. Ber. 27, 715 (1894));  $\text{PhC:N.N:CPh.O}$ , m. 138°,  $b_{10}$  248° (cf.

Rend. accad. Lincei [5] 8, I, 228(1899));  $\text{PhC:N.O.-CPh:N}$ , m. 108°,  $b_{17}$  210° (cf. Ber. 17, 1694(1884));

$\text{PhC:N.O.N:CMc}$ , m. 2°,  $b_{10}$  145° (cf. C. A. 26, 5564)

$\text{PhC:N.N:CMc.O}$ , m. 67°,  $b_{10}$  160° (cf. Stollé, C. A. 6, 1004);  $\text{PhC:N.O.CMc:N}$ , m. 41°,  $b_{10}$  244°,  $b_{10}$

189° (cf. Ber. 18, 1085(1885)); and  $\text{MeC:N.O.CPh:N}$ , m. 57°,  $b_{10}$  218° (cf. Crippa and Galimberti, C. A. 25, 3345). The data confirm the presence and the position of the characteristic line of the C:N group, particularly where both substituents are Ph, *s. c.*, in the 1st 3 compds. above. The oxadiazoles showed the lines of N—N and C—O groups, the azoximes those of C—O and C—N groups, and the furazans no lines within the range.  $\nu = 1000-1250 \text{ cm}^{-1}$  (except the line of Ph). Asym. azoximes which exist in 2 isomeric forms, *s. c.*, the last 2 compds. above, gave essentially the same spectra, with only slight differences in the characteristic lines. The compds. contg. 1 or 2 Me groups gave lines of high frequency and low intensity which could not be correlated with any other lines, and which may arise from oscillations of aliphatic groups with respect to nuclear N atoms. In general the expts. make possible a characterization of the 3 forms which the  $\text{C}_2\text{N}_2\text{O}$  cyclic group may assume, and thus make easier the study of isomers not otherwise

distinguishable.  $\text{PhC:N.O.N:CMc}$  was prepd. by heating  $\beta$ -methylphenylglyoxime with 6 N  $\text{NH}_4\text{OH}$  in an autoclave for 8 hrs. at 180°, which is much more convenient than the method already described (*loc. cit.*).

C. C. Davis

Styphnic acid. II. Bromopicrin, the bromination product of sodium styphnate. Hsueh-Han Lei and Peter P. T. Sah. *Science Repts. Natl. Tsinghua Univ.* A2, 129-31(1933); cf. C. A. 27, 5720.—Bromination of Na styphnate gives a high yield of bromopicrin,  $b_{10}$  89-90°,  $d_4^{20}$  2.7930,  $d_4^{25}$  2.7817,  $n_D^{20}$  1.5790,  $n_D^{25}$  1.5769. On attempting to synthesize guanidine by heating bromopicrin with alc.  $\text{NH}_3$ , the mixt. exploded. W. H. A.

Preparation of esters of chlorosulfonic acid or sulfuric acid. R. Levailant. *Compt. rend.* 197, 335-7(1933).—The following chlorosulfonates were prepd. from  $\text{SO}_2\text{Cl}_2$  and the appropriate alc.:  $\text{C}_6\text{H}_{11}$  (I),  $b_{10}$  76-7°,  $d_4^{20}$  1.250,  $d_4^{25}$  1.225,  $n_D^{20}$  1.4245;  $\text{C}_6\text{H}_{11}$  (II),  $b_{10}$  about 75-6°,  $d_4^{20}$  1.206,  $d_4^{25}$  1.185,  $n_D^{20}$  1.430; 3-chloropropyl (III),  $b_{10}$  about 85°,  $d_4^{20}$  1.483,  $d_4^{25}$  1.456,  $n_D^{20}$  1.457; 2,3-dichloropropyl (IV),  $b_{10}$  122-3°,  $d_4^{20}$  1.609,  $d_4^{25}$  1.582,  $n_D^{20}$  1.481. III and IV are more stable than I and II which in turn are more stable than  $\text{ClSO}_2\text{Pr}$ .  $\text{SOCl}_2$  and the corresponding alcs. gave the following dialkyl sulfates:  $\text{C}_6\text{H}_{11}$ ,  $b_{10}$  134°,  $d_4^{20}$  0.989,  $d_4^{25}$  0.972,  $n_D^{20}$  1.435;  $\text{C}_6\text{H}_{11}$ ,  $b_{10}$  181°,  $d_4^{20}$  0.959,  $d_4^{25}$  0.942,  $n_D^{20}$  1.443; 2-bromoethyl,  $b_{10}$  158-9°,  $d_4^{20}$  1.959,  $d_4^{25}$  1.927,  $n_D^{20}$  1.625; 3-chloropropyl,  $b_{10}$  161-2°,  $d_4^{20}$  1.333,  $d_4^{25}$  1.313,  $n_D^{20}$  1.480; 2,3-dichloropropyl,  $b_{10}$  about 175°,  $d_4^{20}$  1.529,  $d_4^{25}$  1.501,  $n_D^{20}$  1.509. A by-product in the prepn. of  $\text{C}_6\text{H}_{11}\text{OH}$  from  $\text{BuMgBr}$  and  $(\text{CH}_3\text{O})_2$  is diamyl formal,  $b_{10}$  99-101°,  $d_4^{20}$  0.855,  $d_4^{25}$  0.837,  $n_D^{20}$  1.4145.

A. F. Shepard

Esters of chlorosulfonic acid and sulfuric acids. R. Levailant. *Compt. rend.* 197, 648-51(1933); cf. C. A. 24, 824.— $\text{Cl}_2$  passed into  $\text{Bu}_2\text{SO}_4$  gave 96% *Bu chlorosulfonate*. When passed into  $\text{SO}_2(\text{CH}_2\text{CHClCH}_2\text{Cl})_2$  it gave 90%

2,3-dichloropropyl chlorosulfonate. When  $\text{SO}_2(\text{CH}_2\text{CH}_2\text{Br})_2$  was added to  $\text{SO}_2\text{Cl}_2$  81%  *$\beta$ -bromoethyl chlorosulfonate*,  $b_{10}$  103-6°, mol. refraction 34.33 (theory 34.35), was obtained.  $\text{Pr}_2\text{SO}_4$  (I) was prepd. according to reaction (a) given by L. in C. A. 27, 701. Yield 65-70%,  $b_{10}$  110°. I was also prepd. by reaction (b)  $\text{SO}_2\text{R} + \text{ClSO}_2\text{R} = \text{RCl} + \text{SO}_2 + \text{R}_2\text{SO}_4$ . Yield 55-60%.  $\text{Bu}_2\text{SO}_4$  (II) was prepd. by reaction (a). Yield 55%,  $b_{10}$  103-6°,  $b_{10}$  117°,  $d_4^{20}$  1.080,  $d_4^{25}$  1.069,  $n_D^{20}$  1.425, mol. refraction 50.27 (theory 50.23). II prepd. by reaction (b) gave a yield of 70%. *sym-3-Chloropropyl sulfate*, prepd. by reaction (b),  $b_{10}$  160-2°,  $d_4^{20}$  1.384,  $d_4^{25}$  1.363,  $n_D^{20}$  1.400, mol. refraction 50.45 (theory 50.72). W. A. Moore

Nitriles and brominated aliphatic ketones. Pierre Truncl. *Compt. rend.* 197, 453-6(1933).—T. expected that the action of Mg compds. on homologous brominated nitriles (long-chain compds. are used) should lead, after reduction, to cyclic amines of large nucleus. Ketones were obtained and not cyclic amines. 6-Bromoheptanenitrile was prepd. by the action of  $\text{KCN}$  in  $\text{MeOH}$  on dibromopentane. The Br (45.3%) and N (7.8%) contents agreed with the compd.  $\text{C}_6\text{H}_{11}\text{NBr}$ . The product of the reaction of 11 g.  $\text{Br}(\text{CH}_2)_5\text{CN}$  on an excess of  $\text{MeMgBr}$  was poured into a mixt. of ice and  $\text{NH}_4\text{Cl}$ . This mixt. was extd. with ether, dried and distd. under reduced pressure, when a very small quantity was obtained. The Br content agreed with the theoretical. Semicarbazone (in alc.) m. 136°. Both the N (16.9%) and Br (31.8%) agreed with  $\text{C}_6\text{H}_{11}\text{ONBr}$ . 11-Bromo-undecanoic acid, m. 51°, was obtained by adding  $\text{HBr}$  in dry petr. ether soln. to undecylenic acid. 11-Bromo-undecanoyl chloride, obtained by the action of the acid on  $\text{SO}_2\text{Cl}_2$ , is a liquid decompd. under 10 mm. without distg. With aq.  $\text{NH}_3$  the chloride yielded the amide, m. 88°. The yield was 74% starting from the acid. The Br (30.4%) agreed with  $\text{C}_{11}\text{H}_{21}\text{ONBr}$ . The nitrile was obtained by distn. of the amide under reduced pressure in presence of  $\text{P}_2\text{O}_5$ . Yield 70%,  $b_{17}$  184°,  $b_{10}$  161°, mol. refraction 60.72 (calcd. 60.53). Br (32.2%) agreed with  $\text{C}_{11}\text{H}_{21}\text{NBr}$ . The nitrile treated with  $\text{MeMgBr}$  as above yielded a solid ketone, m. 22°,  $b_{10}$  153-4°,  $b_{10}$  148°,  $d_4^{20}$  1.105,  $n_D^{20}$  1.4659, mol. refraction 65.8 (calcd. 65.4). Br agreed with  $\text{C}_{11}\text{H}_{21}\text{ONBr}$ . Semicarbazone, m. 118°, Br (24.8%) agreed with  $\text{C}_{11}\text{H}_{21}\text{ONBr}$ .  $\text{NH}_2(\text{CH}_2)_{10}\text{COMe}$  is prepd. as follows: 11-dodecanone-*N*-phthalimide  $\text{MeCO}(\text{CH}_2)_{10}\text{N}(\text{CO})_2\text{C}_6\text{H}_4$  is prepd. by the action at 250-300° for 5 hrs. of 15 g. *K* phthalimide on 7 g. nitrile. The product, washed with water, dried and crystd. from alc., m. 69°. N (4.20%) agreed with  $\text{C}_{20}\text{H}_{39}\text{O}_2\text{N}$ . Semicarbazone, from alc., m. 146°. The phthalimide is treated in alc. with soda lye to complete soln. Neutralizing ext. with ether and boil the phthalamic acid with 20%  $\text{HCl}$  until dissolved. The amino hydrochloride results, neutralize, ext. with  $\text{C}_6\text{H}_6$ , distil off the solvent, and crystallize from aq. alc., whence a small quantity of well-cryst. solid is obtained. N (6.85%) agreed with  $\text{C}_{11}\text{H}_{21}\text{ON}$ . Prolonged boiling (15 hrs.) of the phthalimide with 20%  $\text{HCl}$  left the phthalimide unaltered; it was necessary to pass through the intermediate phthalamidic acid. The chlorides of acids, amides and nitriles corresponding to the 10-bromoundecanoic acid were prepd. 10-Bromoundecanoic acid was prepd. by the addn. of  $\text{HBr}$  to undecylenic acid in toluene at 0°. 10-Bromo-undecanoyl chloride cannot be distd. The amide (from  $\text{NH}_2$  with chloride) is a solid, sol. in  $\text{C}_6\text{H}_6$ , crystg. from alc., m. 93.5°. N (5.36%) agreed with  $\text{C}_{11}\text{H}_{21}\text{ONBr}$ . 10-Bromoundecanenitrile is a liquid  $b_{10}$  174°. N (5.60%) agreed with  $\text{C}_{11}\text{H}_{21}\text{NBr}$ . H. E. Messmore

Action of formaldehyde on amines and amino acids. H. T. Clarke, H. B. Gillespie and S. Z. Weissman. *J. Am. Chem. Soc.* 55, 4571-87(1933).—Simple aliphatic amines are smoothly methylated to the corresponding tert. amines by warming in  $\text{HCO}_2\text{H}$  with  $\text{HCHO}$ , the yields being over 80%; prepd. in this manner were  $\text{Me-BuN}$ ,  $\text{Me-NCH}_2\text{Ph}$  and methylpiperidine. 1,4-Diaminobutane gives 92% of the tetra-Me deriv., b. 167°.  $\text{RhNH}_2$  gives a viscous oil; 2,4,6- $\text{Br}_3\text{C}_6\text{H}_2\text{NH}_2$  gives 77%

of the tert. amine.  $(\text{PhCH}_2)_3\text{NH}$  and  $\text{HCHO}$  give mainly  $(\text{PhCH}_2)_3\text{NMe}$  together with some  $\text{BzH}$  and a more volatile base, probably  $\text{Me}_2\text{NCH}_2\text{Ph}$ . Tetrabenzylidiaminomethane and 90%  $\text{HCO}_2\text{H}$ , refluxed 8 hrs., give a mixt. of  $(\text{PhCH}_2)_3\text{NMe}$  and  $(\text{PhCH}_2)_3\text{NH}$ ; methylenedipiperidine gives methylpiperidine; benzalbenzylamine, b. 143-4°, gives  $\text{BzH}$  and  $\text{PhCH}_2\text{NH}_2$ . Hexamethylene, tetraamine gives mainly  $\text{NH}_3$  and  $\text{Me}_3\text{N}$ , with smaller amts. of  $\text{MeNH}_2$  and  $\text{Me}_2\text{NH}$ , only 75% of the methylene C reappears as Me in the final mixt. Only about 80% of the anticipated amt. of  $\text{CO}_2$ , calcd. on the assumption that  $\text{HCO}_2\text{H}$  is the sole H donor, is obtained in these reactions; apparently some of the  $\text{HCHO}$  also contributes H.  $\text{NH}_3$  acids react with  $\text{HCHO}$  in warm  $\text{HCO}_2\text{H}$  with detachment of some of the N in the form of volatile bases. Di-Me' derivs. were isolated from the reaction in  $\text{HCO}_2\text{H}$  with glycine,  $\beta$ -alaninopropionic acid,  $\alpha$ -aminoisobutyric acid and  $\alpha$ -amino- $\alpha$ -phenylbutyric acid. Other  $\text{NH}_3$  acids yield breakdown and condensation products of various degrees of complexity.  $\text{BzH}$  was isolated from  $\alpha$ -aminophenylacetic acid,  $\text{PhCOEt}$  from  $\alpha$ -amino- $\alpha$ -phenylbutyric acid and  $\alpha$ -(4-phenyl-2,3-diketopyrrolidyl)- $\beta$ -phenylpropionic acid (I) from phenylalanine. Dimethylglycine-HCl, m. 189-90° (64-7% yield); the free acid is very hygroscopic.  $\beta$ -Dimethylaminopropionic acid-HCl, m. 188-91° (38% yield);  $\alpha$ -dimethylaminoisobutyric acid-HCl, m. 204° (decompn.); Me ester, b. 164-5° (20-5% yield);  $\alpha$ -dimethylamino- $\alpha$ -phenylbutyric acid, m. 220° (decompn.). I, m. 245-6°; the l-isomer m. 250-1°,  $[\alpha]_D^{25}$  -37.6° (2.7% in N NaOH); the l-di-p-methoxy deriv. m. 231°,  $[\alpha]_D^{25}$  -31° (3.0% in N NaOH); the mono-p-MeO deriv. m. 239-40°,  $[\alpha]_D^{25}$  -135.5°, results from l-p-methoxyphenylalanine, phenylpyruvic acid and  $\text{HCHO}$  in  $\text{AcOH}$  on boiling 1 hr. I yields a Ba salt, cmstg. with 3 mols.  $\text{H}_2\text{O}$ ; with  $\text{Ac}_2\text{O}$  it gives an internal anhydride of a mono-Ac deriv.,  $\text{C}_{22}\text{H}_{27}\text{O}_4\text{N}$ , m. 192-4°;  $\text{BzCl}$  gives the compd.  $\text{C}_{22}\text{H}_{27}\text{O}_4\text{N}$ , m. 60°; Me ester, m. 118°; Me ether, amorphous, m. 75-90° (Ba salt; Me ester, m. 78°);  $\text{NH}_4\text{OH}$  gives the compd.  $\text{C}_{10}\text{H}_{11}\text{O}_4\text{N}_2$ , m. 185-6°. Oxidation of I with  $\text{Ag}_2\text{O}$  gives  $\text{BzH}$ ;  $\text{H}_2\text{O}_2$  gives  $\text{BzOH}$  and  $\text{PhCH}_2\text{CO}_2\text{H}$ . Alk. fusion of I gives styrene,  $\text{NH}_3$ ,  $\text{CO}$ , and H. C. J. West

**Alkylation of secondary amines with aldehydes and ketones.** A. Skita, F. Keil and H. Havemann. *Ber.* 66B, 1400-11 (1933).—The readiness with which secondary amines can be alkylated by catalytic reduction in the presence of aldehydes and ketones (C. A. 24, 2421, and earlier papers) made it of interest to det. how widely applicable the new method is. Aldehydes especially serve quite generally as excellent alkylating agents; no disturbing influence due to the mol. size of the amine or of the aldehyde was detected. The yield of tertiary amine is markedly smaller if the 2 alkyl groups on the N of the secondary amine have side chains in the  $\alpha$ -position. Aromatic aldehydes, also, are in general not as well adapted for alkylation as the aliphatic aldehydes; with aromatic aldehydes, the mol. size of the secondary amine influences the extent of alkylation. The presence of Ph groups in the vicinity of the N atom tends to decrease the ease of alkylation. On the other hand, the applicability of ketones in the reaction depends essentially on the mol. size and structure of the secondary amine and the ketone. Secondary amines of medium mol. size with a Me group on the N can be alkylated with ketones which are methylated on the C:O group, but if the Me group is replaced by Et or a higher group the ease of alkylation is greatly diminished. A side chain in the  $\alpha$ -position to the N also decreases the ease of alkylation, and secondary amines with such  $\alpha$ -side chains in both alkyl residues cannot be alkylated at all with ketones. In the 3 methylcyclohexanones, the ability to alkylate secondary amines is greatly diminished when the Me is in the  $\alpha$ -position. Except for aromatic compds. all tertiary amines can be prepd. by the new method when the last alkyl introduced into the secondary amine is such as is produced from an aldehyde (i. e., has no  $\alpha$ -side chain). Thus, the 3 possible combinations from which  $\text{EtCHMeNMeCHMeEt}$  (I) can be produced, viz.,  $\text{MeNHCHMeEt} + \text{Et}_2\text{CO}$ ,  $\text{MeNH}$ -

$\text{CHMeEt} + \text{MeCOEt}$ , and  $\text{EtCHMeNHCHMeEt} + \text{HCHO}$ , give 0.2, 23 and 73% yields, resp. The following amines were prepd: *Ethylisoumylethylamine* (3.5 g. from 10 g. iso-AmNH<sub>2</sub>Et and enanthal), b. 112-13°; *acid oxalate*, m. 75-8°. *Ethylisoumylethyl(3,7-dimethyloctyl)amine* (21 g. from 20 g. iso-AmNH<sub>2</sub>Et and citral), b. 136-7°; *acid oxalate*, m. 81-2°. *Diisoumylethylamine* (6 g. from 15 g. (iso-Am)<sub>2</sub>NH and AcH), b. 75-8° (picrate, m. 95-6°; *picrolonate*, m. 114-15°; *methiodide*, m. 148.5-9.5°); the AcH must partially aldolize in the alk. reaction mixt., for there is also formed 3 g. *diisoumylethylamine*, b. 100-3° (picrate, m. 117-18°), which is obtained in 9 g. yield from 15 g. (iso-Am)<sub>2</sub>NH with  $\text{MeCH:CHCHO}$ . *Diisoumylethyl(3,7-dimethyloctyl)amine*, b. 161-2°, isolated as the *acid oxalate*, m. 112-13° (5.9 g. from 7 g. (iso-Am)<sub>2</sub>NH with citral). *Bis(3,7-dimethyloctyl)ethylamine*, b. 183-8°; *acid oxalate*, m. 94-5° (7 g. from 15 g. (C<sub>10</sub>H<sub>21</sub>)<sub>2</sub>NH with AcH). *Iso-Am homolog*, b. 208°; *acid oxalate*, m. 100-1° (15.5 g. from 15 g. (C<sub>10</sub>H<sub>21</sub>)<sub>2</sub>NH and iso-BuCHO), also obtained in 9 g. yield from 6 g. iso-Am-(C<sub>10</sub>H<sub>21</sub>)<sub>2</sub>NH and 2,6-dimethyl-8-octanal (tetrahydrocitril). *Tris(3,7-dimethyloctyl)amine*, b. 237-4°; *acid oxalate*, m. 105-6° (17 g. from 15 g. (C<sub>10</sub>H<sub>21</sub>)<sub>2</sub>NH and citral, and 12 g. from 8 g. (C<sub>10</sub>H<sub>21</sub>)<sub>2</sub>NH and tetrahydrocitril). *Diisopropylpropylamine* (4 g. from (iso-Pr)<sub>2</sub>NH and EtCHO), b. 145-7°; *picrate*, m. 120-1°. *Bis(1-methylpropyl)heptylamine* (0.9 g. from 9 g. (1-CHMe)<sub>2</sub>NH and enanthal), b. 249-52°; *picrolonate*, m. 105-6°. *Ph<sub>2</sub>NMe* (7 g. from 10 g.  $\text{Ph}_2\text{NH}$  and  $\text{HCHO}$ ), b. 148°.  $\text{Ph}_2\text{NMe}$  (14 g. from 15 g.  $\text{Ph}_2\text{NH}$  with AcH), b. 150°, *di-Br deriv.*, m. 107-8°. *Propyldiphenylamine* (10 g. from 15 g.  $\text{Ph}_2\text{NH}$  with EtCHO), b. 154°; *di-Br deriv.*, m. 76-7°. *Butyldiphenylamine* (7 g. from 16 g.  $\text{Ph}_2\text{NH}$  with  $\text{PrCHO}$ ), b. 104°; *di-Br deriv.*, m. 56-7°. *Iso-butyldiphenylamine* (3 g. from 30 g.  $\text{Ph}_2\text{NH}$  and iso- $\text{PrCHO}$ ), b. 156-7°. *Methylisopropyl(1-methylpropyl)amine* (7 g. from 10 g. EtCHMeNHMe and  $\text{Me}_2\text{CO}$ ), b. 132-3°; *picrate*, m. 142-3°. *Bis(1-methylpropyl)methylamine* (3 g. from EtCHMeNHMe and  $\text{MeCOEt}$ ), b. 155-7°; *picrate*, m. 92-3°. *Methyl(1-methylpropyl)-alkylamines*, EtCHMeNHMeR: *1-methylbutyl* (R =  $\text{Pr-CHMe}$ ) (3 g. from 10 g. EtCHMeNHMe (II) and  $\text{MeCO-Pr}$ ), b. 170-2° (*picrolonate*, m. 130-1°, *picrate*, m. 87-8°); *1-methylamyl* (1.5 g. from 10 g. II and  $\text{MeCO-Bu}$ ), b. 192-3° (*picrolonate*, m. 98-9°); *1-methylhexyl* (0.7 g. from 12 g. II and  $\text{MeCOAm}$ ), b. 211-13° (*picrolonate*, m. 99-100°); *1-methylheptyl* (0.5 g. from 40 g. II and  $\text{MeCOCH}_2\text{H}_3$ ), b. 224-6°; *cyclohexyl* (3 g. from 10 g. II and cyclohexanone), b. 208-9° (*picrate*, m. 110-11°); *4-methylcyclohexyl* (0.8 g. from 10 g. II and p-methylcyclohexanone), b. 221-2° (*picrolonate*, m. 138-9°); *m-isomer* (1 g. from 10 g. II), b. 218-19° (*picrate*, m. 92-3°). *Ethylisopropyl(1-methylpropyl)amine* (0.3 g. from 10 g. EtCHMeNHMe and  $\text{Me}_2\text{CO}$ ), *picrate*, m. 118°. *Ethylisopropylisoumylethylamine* (4 g. from iso-AmNH<sub>2</sub>Et and  $\text{Me}_2\text{CO}$ ), b. 163-4°; *picrate*, m. 80-1°. *Diisoumylethylisopropylamine* (1.4 g. from 8 g. (iso-Am)<sub>2</sub>NH and  $\text{Me}_2\text{CO}$ ), b. 206-8°; *picrate*, m. 80-1°. I, b. 168-71°; *picrolonate*, m. 115-16°. The methyl(1-ethylpropyl)amine, b. 106-7° (*acid oxalate*, m. 142-3°), required for 1 of the methods of prepn. of I was obtained in 11-g. yield from 27 cc. of 20% aq. MeNH<sub>2</sub> and 15 g.  $\text{Et}_2\text{CO}$  with 20 cc. of 1% colloidal Pt soln. The 1-methylpropyl(1-methylpropyl)amine, b. 150-2° (*picrolonate*, m. 187-8°), required for another of the methods of prepn. of I was similarly obtained in 7-g. yield from EtCHMeNH<sub>2</sub> and  $\text{MeCOEt}$ . C. A. R.

**A new color reaction of aldehydes.** P. Rumpf. *Compt. rend.* 197, 337-9 (1933).—The color reaction obtained on adding 1-2 drops of an aldehyde to a few cc. of a cold freshly prepd. soln. of 2-3 mg. rosaniline-HCl in 25 cc. 98%  $\text{HCO}_2\text{H}$  distinguishes 2 general types of aldehydes. Aromatic aldehydes and those where the CHO group is linked to tertiary C increase the color of the reagent, changing the shade but little. Exceptions are  $\text{CH}_3\text{O}$  and  $\text{CCl}_3\text{CHO}$  which give a fuchsin-red color. All aldehydes having a primary or secondary group attached to the CHO slowly change the color to green, the change

being slower with aldehydes of the type  $RCH_2CHO$ .

A. F. Shepard  
The polymerization of gaseous formaldehyde. Robert Spence. *J. Chem. Soc.* 1933, 1198-7.—The polymerization of gaseous  $HCHO$  in Pyrex-glass vessels at room temps. is a surface reaction, unimol. at high pressures and polymol. below 200 mm.; it is not accelerated by ultraviolet light.

G. Calingaert  
Several new substances formed by molds. II. Constitution of gluconic acid. Hermann Sutter and Nadine Wijkman. *Ann.* 505, 248-54 (1933); cf. *C. A.* 25, 1499.—Gluconic acid (I) forms a nitric acid ester, sapon. by  $NaOH$ . Heating I at 230-50° gives 40% of  $\alpha,\beta$ -diethylacrolein (II),  $b_{11}$  42°; catalytic reduction gives  $\alpha,\beta$ -diethylpropionaldehyde,  $b_{10}$  63.4°, whose 2,4-dinitrophenylhydrazones, yellow, m. 123°. II and  $Ag_2O$  give  $PrCH_2CO_2H$ ,  $b_{11}$  103°;  $O_3$  and catalytic reduction gives  $EtCHO$  and  $EtCOCHO$ .

C. J. West  
Recent general methods of condensation of ketones. V. Grignard and J. Colonge. *Bul. soc. chim. Romania* 15, 5-12 (1933); cf. *C. A.* 26, 3231.—Two methods were employed for the condensation of ketones. (a) Condensation by means of  $HCl$ ,  $HBr$  and  $HI$ . In the condensation of ketones of the general formula  $RCOMe$ , if  $R$  is primary or aromatic,  $HCl$  serves as a condensing agent to give a yield of 15%. If  $R$  is secondary  $HBr$  is used (yield 40%). If  $R$  is tertiary no condensation takes place. Ketones of the type  $RCH_2COCH_2R$  are condensable with  $HBr$ . (b) Condensation by means of aminomagnesium halide reagent  $RR'NMgX$  ( $R$  and  $R'$  may be  $H$  or aliphatic radicals). The reaction is analogous to the Grignard reaction. The keto alcs. may be obtained in yields varying between 50 and 70%. Two thirds of a mol. of the ketone in 50-80 cc. benzene is added slowly (20-30 min.) to the aminomagnesium reagent, the temp. being kept at 20°. After standing 1 hr. the calcd. amt. of  $HCl$  is added. The ether-benzene layer is decanted, washed with  $H_2O$  and dried over anhyd.  $Na_2SO_4$ . The ether and benzene are distd. under 50 mm. The keto-alc. compd. is then distd. *in vacuo*. The following keto alcs. were prepd.: 10-methyl-12-keto-10-heneicosanol by condensation of Me nonyl ketone (yield 70%), m. 23°; 2,3,6-trimethyl-5-keto-3-heptanol, by condensation of MeCOCHMe<sub>2</sub> (yield 77%),  $b_{16}$  97°,  $d_4^{25}$  0.910,  $n_D^{25}$  1.4412, mol. refraction 49.93 (theory 49.91); 2,2,3,6,6-pentamethyl-5-keto-3-heptanol, by condensation of pinacolone (yield 70%),  $b_{12}$  103.5°,  $d_4^{25}$  0.896,  $n_D^{25}$  1.4421, mol. refraction 50.07 (theory 50.15); 5-ethyl-4-propyl-6-keto-4-nonanol, by condensation of  $Pr_2CO$ ,  $b_1$  104.5°,  $d_4^{25}$  0.894,  $n_D^{25}$  1.4459, mol. refraction 68.0 (theory 68.38); 3,5,7-trimethyl-4-ethyl-6-keto-4-nonanol, by condensation of 4-methyl-3-hexanone (yield 55%),  $b_1$  104°,  $d_4^{25}$  0.914,  $n_D^{25}$  1.4532; 1-cyclohexanol-2-cyclohexanone, by condensation of cyclohexanone (yield 55%), m. 56°,  $b_1$  116.9°. Its oxime m. 113°. 2,4-Diphenyl-4-keto-2-butanol m. 63°.

W. A. Moore  
Experiments with citral. Marston T. Bogert and Victor G. Fournier. *Am. Perfumer* 28, 345-7 (1933).—Citral,  $b_{12}$  110-12°, can be converted into *p*-cymene in 68% yield or better by distn. with small quantities of  $I$ . It can also be condensed with cyclohexanone, in the presence of  $NaOEt$ , with the formation of *mono-* and *dicitrylidene-cyclohexanones*. The mono deriv.,  $C_{16}H_{24}O$ , is a colorless, odorless liquid  $b_{12}$  156-60°,  $d_{20}$  0.9498,  $n_D^{25}$  1.54303. The di. deriv.,  $C_{26}H_{42}O$ ,  $b_2$  196-200°, forms a yellow viscous liquid of weak aroma, which is somewhat similar to the very faint odor of pseudoionone. It congealed in a freezing mixt., but could not be crystd. satisfactorily. By refluxing citrylidene-cyclohexanone with  $CH_2O_2$ , it is cyclized to the *cyclocitrylidene-cyclohexanone*,  $C_{16}H_{24}O$ ,  $b_2$  132-4°, possessing a cedar-like odor, when dil. somewhat recalling that of ionone, whereas the uncyclized compd. is practically odorless. Thus, in the matter of odor and in the drop of 20° in b. p., the resemblance of this cyclized product to its uncyclized progenitor is not unlike that of ionone to pseudoionone. Attempts to cyclize the citrylidene-cyclohexanone by the action of either  $H_3PO_4$  or  $H_2SO_4$  under various conditions proved futile.

W. O. E.  
Esterification velocity of alcohols in formic acid. II. Anton Kailan and Naftaly H. Friedmann. *Monatsh.* 62, 284-316 (1933); cf. *C. A.* 26, 3207.—The esterification velocity at 15° of  $EtOH$ ,  $PrOH$ ,  $BuOH$ , 2-methylpropanol, 2-methylbutan-1-ol, octan-1-ol, propan-2-ol, butan-2-ol, octan-2-ol and 2-methylbutan-2-ol in  $HCO_2H$  contg. various amts. of  $H_2O$  and of the last 5 alcs. also in the presence of  $HCl$  was detd. by measuring the increase of the f.-p. lowering, and the velocity const. was calcd. from the equation for a monomol. reaction. For solns. of  $C_6H_5$ ,  $BzOH$ ,  $CHCl_3$  and several formic esters in  $HCO_2H$  the apparent f.-p. consts. are independent of the  $H_2O$  content. For solns. of 0.3-2.1 mols.  $H_2O$  per kg.  $HCO_2H$  the mol. depression is 2.44°, independent of the concn. of the  $H_2O$ . The alcs. are practically completely esterified. Increase in the  $H_2O$  content, with or without  $HCl$ , causes a decrease in the velocity const. Without  $HCl$  the alcs. are esterified 15,000-20,000 times as rapidly in  $HCO_2H$  as in  $AcOH$ ; with  $HCl$  and low  $H_2O$  content, 8000-10,000 and with larger  $H_2O$  content about 2000 times as fast as in  $AcOH$ .

C. J. West  
 $\alpha$ -Chlorovinylacetates. R. Rambaud. *Compt. rend.* 197, 767-70 (1933); cf. *C. A.* 27, 2423.— $CH_2:CHCH(OH)CO_2Me$  (I) and  $CH_2:CHCH(OH)CO_2Pr$  gave with  $SOCl_2$ , resp., the corresponding  $\alpha$ -Cl compds.  $b_{10}$  55°,  $d_{15}$  1.1311,  $n_D^{25}$  1.440, and  $b_{17}$  75°,  $d_{15}$  1.046,  $n_D^{25}$  1.438. Likewise  $CH_2:CHCH(OH)CN$  gave the  $\alpha$ -Cl deriv., b. 133-4°,  $n_D^{25}$  1.441,  $d_{15}$  1.073. I boiled with dil.  $HCl$  on a water bath gave the free Cl acid,  $b_{11}$  103-4°,  $d_{15}$  1.237,  $n_D^{25}$  1.457. Julius White  
Sorbyl chloride. II. T. Reichstein and G. Trivelli. *Helv. Chim. Acta* 16, 968-75 (1933); cf. *C. A.* 26, 2701.—Sorbyl chloride ( $MeCH:CHCH:CHCH_2Cl$ ) (I) and  $PhONa$  give *o*-sorbylphenol,  $b_{11}$  100°, catalytically reduced to *o*-hexylphenol,  $b_{10}$  100°; another product is neutral,  $b_{10}$  72°,  $b_{17}$  245°. I,  $MeMgI$  and  $CO_2$  give 1,4-hexadiene-3-carboxylic acid,  $b_{11}$  100°, reduced to  $EtPrCHCO_2H$ ; the neutral part,  $C_{12}H_{18}$ ,  $b_{11}$  90-5°, results in better yield from I and Cu-Mg alloy in abs.  $Et_2O$ ;  $O_3$  gives succinic acid. I is obtained in 8-g. yield from 11.6 g. acid, 14.3 g.  $SOCl_2$  and 9.52 g.  $C_6H_5N$ ; it  $b_{12}$  45.5°,  $d_4^{25}$  0.9434,  $n_D^{25}$  1.5037.

C. J. West  
Mechanism of substitution in organic compounds. Elimination of bromine from bromoacetic acid and the bromoacetates. H. M. Dawson and N. B. Dyson. *J. Chem. Soc.* 1933, 1133-43.—The kinetic study of the substitution of  $Br$  by the  $HO$  group in solns. which contain bromoacetate ions ( $A'$ ) and bromoacetic acid mols. ( $HA$ ) has shown that 4 simultaneous reactions are involved. In each of these reactions the bromide ion is liberated in the primary stage, and the observed rate of this process can be represented very closely by the equation  $v = v_1 + v_2 + v_3 + v_4 = k_1[A'] + k_2[A']^2 + k_3[HA] + k_4[HA][A']$  when the very considerable disturbing effects due to the reaction products and to variations in the nature of the reaction medium are eliminated. When the compn. of the reacting soln. is suitably varied, any one of the 4 component reactions may be made the dominant factor in the observed rate of change. Under certain conditions the general velocity equation reduces to very simple forms which have facilitated the detn. of the several velocity coeffs. When equiv. solns. of bromoacetic acid and of Na bromoacetate are mixed in various proportions, the velocity-compn. curve shows a well-defined max. The retardation effects observed with solns. of bromoacetic acid are mainly due to the gradual elimination of the mol.-ion reaction ( $v_4$ ) as the result of the formation of  $HBr$  and consequent fall in the concn. of the bromoacetate ion. The progressive acceleration effects observed with solns. of Na bromoacetate are due to the intervention of other reactions in which glycolic acid is directly or indirectly concerned.

G. C.  
Oxidation of 1,2-glycols with lead tetraacetate and periodic acid. P. Karrer and Ryuzo Hirohata. *Helv. Chim. Acta* 16, 959-92 (1933).—The relative merits of the oxidation cleavage of the 1,2-glycols by the methods of Malaprade (*C. A.* 22, 3374) and Griegee (*C. A.* 25, 8314), with  $HIO_4$  and  $Pb(OAc)_4$ , resp., have been com-

pared. The yields of cleavage products ( $\text{Me}_2\text{CHCH}_2\text{CH}_2\text{CO}_2\text{H}$ ,  $\text{Me}_2\text{CHCH}_2\text{CH}_2\text{CO}_2\text{H}$  and  $\text{MeAc}$  from  $\text{Me}_2\text{CHCH}_2\text{CH}_2\text{CH}(\text{OH})\text{C}(\text{OH})\text{Me}$ , and  $\text{BzH}$ ,  $\text{BzOH}$  and  $\text{MeAc}$  from  $\text{PhCH}_2(\text{OH})\text{C}(\text{OH})\text{Me}$ ) were similar for both methods. The use of  $\text{HIO}_4$  is recommended for reactions in aq. soln. Otherwise the ease of removal of the Pb salts favors the use of the  $\text{Pb}(\text{OAc})_4$  method.

C. R. Addmell

**Glycol splitting, its mechanism and its use in chemical problems.** Rudolf Criegee, Ludwig Kraft and Bodo Bank. *Ann.* 507, 159-97 (1933).—Glycol splitting refers to the oxidative splitting off of  $\alpha$ -glycols by  $\text{Pb}(\text{OAc})_4$  to form aldehydes or ketones. The reaction may also be applied to  $\alpha$ -HO acids,  $\alpha$ -NH<sub>2</sub> acids and  $\alpha$ -HO amines. Other oxidizing agents may also be used. The velocity of oxidation varies considerably, thus acenaphthenediol has  $k_{25}$  120,000, gluconic  $\alpha$ -lactone 1.2 and cholestatriol 0.002. Data are given for 32 compds. This is principally detd. by steric influences. The *cis*-compd. is oxidized more rapidly than the *trans*-compd. The solvent plays an important part, thus, cyclohexandiol shows a half-period (in sec.) in  $\text{AcOH}$  of 4340, in  $\text{C}_6\text{H}_6$  1.8,  $\text{PhNO}_2$  1.6,  $\text{C}_2\text{H}_5\text{Cl}$  1.1 and  $\text{C}_2\text{H}_5\text{Cl}_2$  0.9. The kinetics of the reaction are discussed.  $\text{Pb}(\text{OAc})_4$  (50 g.) contg. some  $\text{AcOH}$ , shaken with 1 l.  $\text{MeOH}$ , disappears in 0.5 hr., giving a yellow ppt.; addn. of 1 cc.  $\text{H}_2\text{O}$  and shaking for 1 hr. gives *hydroxymethoxylead* (IV) acetate,  $\text{Pb}(\text{OAc})_2(\text{OMe})\text{OH}$ , citron-yellow, which darkens in moist air;  $\text{AcOH}$  or  $\text{Ac}_2\text{O}$  regenerates  $\text{Pb}(\text{OAc})_4$ . In the same way were prepd. the *propionate*, yellow, from  $\text{Pb}(\text{O}_2\text{CPr})_4$  and  $\text{MeOH}$ ; the *butyrate*, light yellow. Dry  $\text{Pb}(\text{OAc})_4$  and  $\text{MeOH}$ , on standing 5 days, give 81%  $\text{HCHO}$ ,  $\text{EtOH}$  gives 89%  $\text{AcH}$ ; 100- $\text{PrOH}$  gives 98%  $\text{Me}_2\text{CO}$ ,  $\text{PhCH}_2\text{OH}$  gives 66% of  $\text{BzH}$ .  $\text{Th}(\text{OAc})_3$  and  $\text{MeOH}$  give *methoxythallacetate*; the *EtO* and *iso-PrO* complexes were also prepd.  $\text{Mn}(\text{OAc})_3$  and  $\text{MeOH}$  give *dimethoxymanganese* (III) acetate, brown. Acenaphthenediol, m. 204-10°, and  $\text{Pb}(\text{OAc})_4$ , shaken in  $\text{C}_6\text{H}_6$  for 15 min., give *naphthaldehyde hydrate*, m. 130-30.4°; *bis-p-nitrophenylhydrazones*, red-brown, decomp. 229°. The *cis*-diol forms an *acetone* complex, m. 75.6-82°, the *trans*-diol, m. 158.5-95°, is unchanged in  $\text{Me}_2\text{CO}$ . 1,2-Dimethylacenaphthenediol gives *perris-diacetylnaphthalene*, m. 171-2°, which gives *3-methyl-perris-naphthinden-1-one*, yellow, m. 156°, with piperidine. 1,2-Diphenylacenaphthenediol and  $\text{Pb}(\text{OAc})_4$  in  $\text{AcOH}$  give *perris-dibenzoylnaphthalene*, m. 176-7°. 9,10-Diphenylidihydrophenanthrene diol gives  $(\text{o-BzC}_6\text{H}_4)_2$ , m. 168-9°. C. J. W.

**Some new types of chelated platinumamines** H. D. K. Drew and H. J. Tress. *J. Chem. Soc.* 1933, 1336-41. It was desired to find whether it was possible to insert large chelate groups across the  $\beta$ -positions of the bivalent Pt atom; and also whether the  $\alpha$ -positions, never yet shown to be bridged, could be spanned by sufficiently large groups. The results prove that with  $\text{C}_2\text{H}_5(\text{NH}_2)_2$  (I) and  $\text{C}_4\text{H}_9(\text{NH}_2)_2$  (II) the chelate loops span the  $\beta$ -positions, giving sparingly sol.  $\beta$ -diammines of normal type, but that on passing to  $\text{C}_4\text{H}_9(\text{NH}_2)_2$  (III) and  $\text{C}_6\text{H}_{13}(\text{NH}_2)_2$  (IV) a sudden change in the character of the products occurs, only ill-defined insol. products being obtained. It appears that III and IV are unable to form loops at a single Pt atom, presumably because this would involve the setting up of highly strained 7- and 8-membered rings; the formation of 5- and 6-membered rings contg. a Pt atom is, however, feasible, and therefore I and II are able to give normal monomeric compds. Aq.  $\text{K}_2\text{PtCl}_4$  and II at room temp. give  $\beta$ -trimethylenediaminoplatinous chloride (V), yellow;  $\text{H}_2\text{O}_2$  in dil.  $\text{HCl}$  gives the *platinsic chloride*, lemon-yellow; V and II give  $\beta$ -bis(trimethylenediaminoplatinous) chloride, which forms a flesh-colored *plato salt*,  $\text{C}_4\text{H}_9\text{N}_4\text{Cl}_4\text{Pt}_2$ .  $\text{H}_2\text{O}_2$  gives the *platinsic chloride*, which also forms a *plato salt*,  $\text{C}_4\text{H}_9\text{N}_4\text{Cl}_4\text{Pt}_2$ , orange. Heating V in 6 N  $\text{HCl}$  at 100° for 7 hrs. gives the  $\alpha$ -dihydrochloride,  $\text{C}_4\text{H}_9\text{N}_4\text{Cl}_4\text{Pt}$ . V and aq. I give  $\beta$ -ethylenediaminotrimethylenediaminoplatinous chloride (VI), which forms a pink *plato salt*, the *platinsic chloride*, which also gives an orange *plato salt*. The  $\alpha$ -dihydrochloride of VI and  $\text{K}_2\text{PtCl}_4$  give the pinkish brown *chloroplatinite*,  $\text{C}_4\text{H}_{12}\text{N}_4\text{Cl}_4\text{Pt}_2$ . V and  $\text{NH}_4\text{OH}$  give  $\beta$ -

diamminotrimethylenediaminoplatinous chloride (VII), which forms a pink *plato salt*;  $\text{H}_2\text{O}_2$  gives the *platinsic chloride*, which gives a brown *plato salt*. VII and 6 N  $\text{HCl}$  give  $\beta$ -aminotrimethylenediaminoplatinous chloride, forming a pink *plato salt*. The  $\alpha$ -monohydrochloride is yellow and reacts with  $\text{K}_2\text{PtCl}_4$  to give  $[\text{PtCl}(\text{NH}_2)_2]_2\text{PtCl}_4$ . [Pt I  $\text{Cl}_4$ ] and hot aq. [Pt( $\text{NH}_2$ )<sub>4</sub>] $\text{Cl}_2$  give [Pt I  $\text{Cl}_4$ ] or [Pt I  $\text{Cl}_4$ ]<sub>2</sub>, red plates; it is oxidized to [Pt I  $\text{Cl}_4$ ] by  $\text{H}_2\text{O}_2$ - $\text{HCl}$  and reduced to [Pt I  $\text{Cl}_4$ ] by aq.  $(\text{CO}_3\text{K})_2$ . This is quite different from the unstable buff *bisethylenediaminoplatinous chloroplatinite* and the buff *dichlorobisethylenediaminoplatinous chloroplatinite*, which were pptd. from aq. solns. of the corresponding chlorides  $\beta$ -[Pt I  $\text{Cl}_4$ ] and 6 N  $\text{HCl}$ , boiled 5 hrs., give [Pt I  $\text{Cl}_4$ ], (I  $\text{H}_2$ ) $\text{PtCl}_4$  and probably (I  $\text{H}_2$ ) $\text{PtCl}_4$ . Similarly  $\beta$ -[Pt II  $\text{Cl}_4$ ] gives [Pt II  $\text{Cl}_4$ ] and (II  $\text{H}_2$ ) $\text{PtCl}_4$ . C. J. West

**Preparation of phosphorylated glyceraldehyde.** H. K. Barrnisch and Luise Klebmann-Messner. *Biochem. Z.* 265, 157-8 (1933).—Glyceraldehyde di-Et acetal is the starting point in the synthesis. Acrolein is prepd. by distn. of glycerol with  $\text{H}_3\text{PO}_4$ , which can be carried out in a Pyrex flask. The glyceraldehyde acetal is obtained from the di-Et acetal of chloropropionic aldehyde and of acrolein acetal, and is phosphorylated in pyridine with  $\text{POCl}_3$ . The addn. of the pyridine soln. of  $\text{POCl}_3$  should be done at temps. of -10 to -16° over a period of 6-8 hrs. This is then poured into cold water, neutralized with milk of lime and the pyridine distd. off *in vacuo*. Evapd. to a small bulk and filtered, the soln. is mixed with several vols. of alc. to ppt. the Ca salt. Purification is brought about by repeated pptn., the product being easily sol. in water. The  $\text{H}_3\text{PO}_4$  ester of glyceraldehyde is directly fermented by yeast. S. M.

**Insect waxes. VI. Synthesis of triglycerides of palmitic and myristic acids.** Fr. N. Schulz and Max Becker. *Biochem. Z.* 264, 87-93 (1933); cf. C. A. 27, 4313.—The various mixed triglycerides of palmitic and myristic acids were synthesized. They had m. ps. between 53.5° and 56.8° which is much higher than that of *Schiso neuera* wax (48.4°), so that the synthetic products are not identical with the natural product. S. M.

**The manufacture of pentaerythritol.** H. Molinari. *Giorn. chim. ind. applicata* 15, 325-8 (1933).—The advantages and disadvantages of  $\text{NaOH}$  and  $\text{CaO}$  as catalysts in the manuf. of pentaerythritol are outlined.

A. W. Conliffe

**Acetone derivatives of d ribose.** P. A. Levene and I. R. Stuller. *J. Biol. Chem.* 102, 187-201 (1933). *d*-Ribose forms only a monoacetone deriv., 2,1-monoacetone ribofuranose. *d*-Ribose (20 g.) was treated with  $\text{MeOH}$ -free  $\text{Me}_2\text{CO}$  in the presence of  $\text{H}_2\text{SO}_4$  and anhyd.  $\text{CuSO}_4$  at 37°, yielding 14 g. of a syrup (A) and 3.0 g. of cryst. material (B). For the purpose of purification, A,  $b_p$  110-7°, was acetylated in  $\text{C}_2\text{H}_5\text{N}$ , giving a *di-Ac deriv.*,  $b_p$  119-21°,  $n_D^{20}$  1.4476,  $\text{C}_{15}\text{H}_{21}\text{O}_6\text{Ac}_2$ ; treatment with  $\text{Ba}(\text{OMe})_2$  in  $\text{MeOH}$  gave syrupy *monoacetone-ribose* (I),  $n_D^{20}$  1.4042,  $\text{C}_{15}\text{H}_{21}\text{O}_6$ , which could react with  $\text{NaOI}$ , a proof that the first C atom was not blocked by the  $\text{Me}_2\text{C}$  group. Methylation of I with Purdie's reagents produced *methyl monoacetone-methylribose*,  $\text{C}_{15}\text{H}_{21}\text{O}_6(\text{OMe})$ ,  $b_p$  62-5°,  $n_D^{20}$  1.4383, which remained unchanged when heated with  $\text{MeOH}$  +  $\text{HCl}$ . Hydrolysis with 0.04 N  $\text{HCl}$  at 100° gave *monomethylribose* (II)  $\text{C}_5\text{H}_{11}\text{O}_5$ , the rate of glucoside formation of which, in  $\text{MeOH}$  +  $\text{HCl}$  at room temp. and 70°, indicated a 1,4-ring structure, thus allowing the allocation of the  $\text{Me}$  group to position 5. II formed a *p-bromophenyllosazone*, m. 161-2°,  $[\alpha]_D^{25}$  -48.0 (in abs. alc.- $\text{C}_2\text{H}_5\text{N}$ , 3:2). On exhaustive methylation, II gave *trimethylmethylribose*,  $b_p$  68°,  $n_D^{20}$  1.4309; hydrolysis with 0.07 N  $\text{HCl}$  at 75° gave *trimethylribose*,  $b_p$  90-2°,  $n_D^{20}$  1.4527,  $[\alpha]_D^{25}$  39.3 (in abs.  $\text{MeOH}$ , 40.6° in  $\text{H}_2\text{O}$  and 43.4° in dil.  $\text{NH}_4\text{OH}$ , identical with the *trimethylribofuranose* of Levene and Tipson (C. A. 26, 5571); oxidation with  $\text{Br}_2$  and lactonization of the acid by heating at 100° for 5 hrs. at 15 mm. gave a syrup,  $b_p$  90-3°,  $n_D^{20}$  1.4508,  $[\alpha]_D^{25}$  56.8° in  $\text{CHCl}_3$  -14.0 (mutal) in  $\text{H}_2\text{O}$ ; after 26 hrs. in  $\text{H}_2\text{O}$ ,  $[\alpha]$  was still neg., this behavior identified it with *trimethylery-*

*ribonolactone* (C. A. 26, 897, 3433). Treatment of I with  $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Cl}$  gave a *di-p-tolylsulfonyl deriv.*, m.  $122-3^\circ$ ,  $\text{C}_{22}\text{H}_{20}\text{O}_6\text{S}_2$ ; boiled with  $\text{NaI} + \text{Me}_2\text{CO}$ , this gave *mono-p-tolylsulfonylmonoisodomonocetoneribofuranose*,  $\text{C}_{11}\text{H}_{12}\text{O}_8\text{S}$ , m.  $120^\circ$  (abs. alc.),  $[\alpha]_D^{25}$   $84.0^\circ$  ( $\text{CHCl}_3$ ); which reacted with  $\text{AgNO}_3$  in  $\text{MeCN}$  to give *mono-p-tolylsulfonylmononitromonocetoneribofuranose*,  $\text{C}_{11}\text{H}_{11}\text{O}_8\text{NS}$ , m.  $156^\circ$ . The fact that one *p-tolylsulfonyl* group could be removed easily showed that it occupied position 5 (C. A. 26, 908). Monocetoneribose has a 1,4-ring and OH groups on C atoms 1 and 5 unsubstituted; therefore, the isopropylidene group must be in positions 2,3. Cryst. material B, b.  $55-60^\circ$ , m.  $61-2^\circ$  (from  $\text{MeOH}$  or pentane),  $[\alpha]_D^{25}$   $-04.35^\circ$  (in  $\text{MeOH}$ ), formula  $\text{C}_5\text{H}_{10}\text{O}_4$ , mol. wt. 171.1, was very unreactive although it could be hydrolyzed with  $\text{HCl}$ , and was assumed to be *2,3-monocetone-1,5-anhydribofuranose*. A condensation in which  $\text{HCl}$  replaced  $\text{H}_2\text{SO}_4$  gave a small amt. of cryst. material of the same compn., m.  $93-4^\circ$ . M. P. Benoy

**Polymerization and ring formation. XVIII.** Polyesters from  $\omega$ -hydroxydecanoic acid. Wallace H. Carothers and Frank J. Van Natta. *J. Am. Chem. Soc.* 55, 4714-19 (1933); cf. C. A. 26, 2707. Polyesters have been prepd. from  $\omega$ -hydroxydecanoic acid with mol. wts. from 780 to 25,200. The m. ps. vary from  $66-7^\circ$  to  $75-80^\circ$ ,  $d_4^{25}$  1.0957 to 1.0621,  $n_D^{25}$  1.4494 to 1.4515. Strong, oriented fibers are obtained only from members having mol. wts. above 9330; a polyester with a mol. wt. of 16,900 had a tensile strength of 13.1 kg./mm.<sup>2</sup>; 20,700, 12.3; 25,200, 7.0. The influence of mol. wt. on some other phys. properties is discussed. C. J. West

The conditions of fixation of  $\text{SbO}_2\text{H}$  by some monoacid monoalcohols. Volmar and Duquenois. *Compt. rend.* 197, 599 (1933). Glycolic, lactic and  $\alpha$ -hydroxyisobutyric acids fix antimony acid. The corresponding emetics have been isolated in cryst. state. The emetic from Na glycolic acid,  $\text{HOSb}(\text{OCH}_2\text{CO}_2\text{H})_2 \cdot \text{H}_2\text{O}$ , is representative of the group as to formula. For each  $\alpha$ -monoacid monoalc., the fixation is at a max. when half the acid is salted. The free acid fixes  $\text{SbO}_2\text{H}$  feebly; the neutral salt does not fix more than a trace. Between the 2 extremes, the curve of fixation as a function of the acidity is at a max. when it corresponds to the neutralization of half the acid by an alk. base, i. e., equimol. mixt. of acid and of alk. salt. W. J. Peterson

Model experiments on the oxidative degradation of biologically important organic sulfur compounds. Alfons Schöberl. *Ann.* 507, 111-27 (1933). In the oxidation of  $\text{HSCH}_2\text{CO}_2\text{H}$  in  $\text{Ba}(\text{OH})_2$  by  $\text{O}_2$  at  $37^\circ$  much more  $\text{O}_2$  is absorbed than is required to form the disulfide. The oxidation products consist of the Ba salts of  $(\text{CO}_2\text{H})_2$ ,  $\text{H}_2\text{S}_2\text{O}_4$  and probably  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_3$  in very small quantities. Oxidation in  $\text{NaOH}$  gives  $(\text{CO}_2\text{Na})_2$  and  $\text{Na}_2\text{S}_2\text{O}_4$ ; Cu is an active catalyst. The oxidation velocity shows a sp. dependence upon the alkali concn. Oxidation to the disulfide step occurs in 4.5 min. Independent of the time of oxidation, the yield of  $(\text{CO}_2\text{H})_2$  is 68.5%. Without catalyst the decompn. is essentially slower but in the same direction. Dithiodiglycolic acid (I), the primary oxidation product, behaves in the same way toward  $\text{O}_2$  in alk. soln., giving 68.1%  $(\text{CO}_2\text{H})_2$ ; this is due to the instability of I toward alkali,  $\text{HSCH}_2\text{CO}_2\text{H}$  being formed in 59.6% yield; unexpectedly 10.1%  $(\text{CO}_2\text{H})_2$  is formed. Oxidation of  $\text{Na}_2\text{S}$  in alk. soln. gives  $\text{Na}_2\text{S}$ ,  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{S}_2\text{O}_3$ ; the amt. of the 1st 2 products increases with increasing alkali concn. and with the presence of Cu. Reduction of I and of dithiodilactic acid (II) with  $\text{Na}_2\text{S}$  is also reported. Alk. degradation of II gives 46.94% of thiolactic acid, whose oxidation in alk. soln. is also studied. II is not oxidized. C. J. W.

Amino acids and related compounds. VII. Oxidation of various amino acids. Yoshitaro Takayama. *Bull. Chem. Soc. Japan* 8, 213-30 (1933). A no. of amino acids were oxidized electrolytically under the following conditions: 30 millimols. of acid in 30 cc. of 2 N  $\text{H}_2\text{SO}_4$  were electrolyzed in a small glass cell. The anode was  $\text{PtO}_2$ , cathode Pb ( $2 \times 4$  cm.), temp.  $30$  or  $35^\circ$ , c.  $2$  amp./sq. cm. When 2F/mol., 4F/mol., etc. had been

passed the electrolysis was interrupted. The quantity of  $\text{CO}_2$  evolved was detd. from absorption tubes and the total N and  $\text{NH}_3\text{-N}$  were detd. in the electrolyte. The  $\text{NH}_3$  and  $\text{CO}_2$  quantities were plotted. The curves representing the formation of  $\text{NH}_3$  and  $\text{CO}_2$  for tyrosine and phenylalanine nearly coincide. The  $\text{NH}_3$  curves of alanine and glutaric acid coincide while their  $\text{CO}_2$  curves do not. Glutamic acid decompn. to succinic acid which in turn yields to anodic oxidation, thereby giving more  $\text{CO}_2$  than alanine, which oxidizes to  $\text{AcOH}$ . Aspartic acid gives still more  $\text{CO}_2$  since it yields malonic acid. The  $\text{NH}_3$  curves of glycine and valine are similar to that of alanine. Leucine evolves less  $\text{NH}_3$ . These latter 3 compds. evolve more  $\text{CO}_2$  than alanine. The  $\text{NH}_3$  curve for a pyrrolidone-carboxylic acid is the highest of all amino acids. This acid and proline yielded succinimide. Histidine and imidazolylpropionic acid were attacked at their imidazole nucleus, the former yielding some urea. Tryptophan and lysine yield normal curves. The monamino-carboxylic acids studied can be divided into 3 groups according to the ease of oxidation by consideration of their  $\text{NH}_3$  curves. (1) Glycine, valine, alanine and glutamic acid give curves which are close together and yield most  $\text{NH}_3$ . (2) The tyrosine and phenylalanine yield less  $\text{NH}_3$ , while (3) leucine and aspartic acid yield a quantity of  $\text{NH}_3$  between that of the other 2 groups. H. E. M.

The deamination of glycine by pyrocatechol derivatives and the proof of glyoxylic acid as intermediary product. H. K. Barrenscheen and Wolfgang Danzer. *Z. physiol. Chem.* 220, 57-60 (1933).—The oxidative deamination of glycine by  $\text{O}_2$  is catalyzed not only by adrenaline, as shown by Edlbacher and Kraus (C. A. 23, 2485), but also by related derivs., notably  $\alpha\text{-C}_6\text{H}_4(\text{OH})_2$ ,  $3,4\text{-(HO)}_2\text{-C}_6\text{H}_3\text{COCH}_2\text{NH}_2$ ,  $3,4\text{-(HO)}_2\text{-C}_6\text{H}_3\text{COCH}_2\text{NHMe}$  and  $3,4\text{-(HO)}_2\text{-C}_6\text{H}_3\text{COCH}_2\text{NHEt}$ . The reaction is more energetic at  $pH$  7.7 than at 6.8, though at the higher  $pH$  the amino catalysts tend to ppt. In the catalysis by adrenaline the intermediate product  $\text{OHCCO}_2\text{H}$  was captured by  $2,4\text{-(O}_2\text{N)}_2\text{-C}_6\text{H}_3\text{NHNH}_2$  and identified as the corresponding hydrazone. The final products are  $\text{NH}_3$ ,  $\text{CH}_2\text{O}$  and  $\text{CO}_2$ . A. W. Dox

The behavior of several urea derivatives, amino acids and peptides with animal black. K. Wunderly. *Helv. Chim. Acta* 16, 1009-13 (1933).—It has been shown that urea, biuret, barbituric acid, urethan, phenylurethan, hydantoic acid and di-ketopiperazine are stable when heated in dil. aq. soln. with animal and sugar black in the absence of  $\text{O}_2$ . Under similar conditions with animal black at  $80^\circ$  serine and sarcosine are deaminated 20% and 5%, resp., and *dl*-glycylglycine and *dl*-leucylglycylglycine 40 and 8%, resp. The deaminating effect of charcoal is sp. for the true amino acid grouping. C. R. Addinall

Action of carbon monoxide on iron and cobalt complexes of cysteine. Maxwell P. Schubert. *J. Am. Chem. Soc.* 55, 4503-70 (1933).—The complex *ferro bisacrylate diacrybonyl* has been crystd. as a free acid,  $\text{Fe}(\text{SCH}_2\text{CHNH}_2\text{CO}_2\text{H})_2 \cdot 2\text{CO}_2\text{H}_2\text{O}$ , yellow, and as the Na salt with 2  $\text{H}_2\text{O}$ ; the acid results from 3.9 g.  $\text{FeSO}_4 \cdot (\text{NH}_4)_2 \cdot \text{SO}_4 \cdot 6\text{H}_2\text{O}$ , 3.2 g. cysteine-HCl, 20 cc.  $\text{H}_2\text{O}$  and 8 cc. 6.5 M KOH in H on passing CO for 4 hrs. The action of CO on K Co bisacrylate involves oxidation and reduction, the products being the green K Co trisacrylate,  $\text{K}_3[\text{Co}(\text{SR})_3] \cdot 3\text{H}_2\text{O}$  (I) and a new complex, isolated as the Ag and Hg compds., apparently derived from  $\text{H}[\text{Co}(\text{CO})_4]$  (II). The Hg salt m.  $82^\circ$ . The action of CO on I in strong alkali also involves oxidation and reduction, the products being carbonate and II. II with acid gives  $\text{Co}(\text{CO})_4$ , which reacts with cysteine and alkali to give I and II. C. J. West

Methylenebutanolone. H. Gault and L. A. Germann. *Compt. rend.* 197, 620-1 (1933). Methylenebutanolone, b.  $92-5^\circ$ , is formed as a side product in the prepn. of butanolone by the reaction of  $\text{Me}_2\text{CO}$  with 2  $\text{CH}_3\text{I}$  and loss of  $\text{H}_2\text{O}$ . It adds  $\text{Br}_2$  to form a dibromide and forms a satd. ketol (b.  $96^\circ$ ; phenylhydrazone m.  $107^\circ$ ) identical with the methylbutanolone formed from  $\text{MeCOEt}$  and  $\text{CH}_3\text{O}$ . Janet E. Austin

**Constitution of ascorbic acid.** R. W. Herbert, E. L. Hirst, E. G. V. Percival, R. J. W. Reynolds and F. Smith. *J. Chem. Soc.* 1933, 1270-90; cf. *C. A.* 26, 3242, 5498; Hirst, *et al.*, *C. A.* 27, 1383, 3190, 4777.—The previous name, hexuronic acid, has been changed to ascorbic acid (I) because the compd. is not really a member of the uronic acid class. The original must be consulted for the long theoretical discussion. I, m. 192°,  $[\alpha]_D^{25}$  24° (H<sub>2</sub>O, c 3), 25° (c 0.5), 24° (c 1.1) and shows no mutarotation,  $[\alpha]_D^{22}$  22° (0.05 N HCl or N H<sub>2</sub>SO<sub>4</sub>); Na salt,  $[\alpha]_D^{25}$  116° (neutral aq. soln.), 130° (0.05 N NaOH), 149° (N/7 NaOH), 153° (0.5 N NaOH), 161° (2 N NaOH, const. for 1 hr.). In 50% AcOH I reacts rapidly (10-15 min.) with O<sub>2</sub>, giving the same product (1st oxidation product (II)) as that produced by oxidation with I<sup>+</sup> or Cl in acid soln.; continued action gives (CO<sub>2</sub>H). The titration with I and Cl is discussed and the absorption spectra are given as a series of curves (I, Na salt, and various oxidation products). II, newly formed, has  $[\alpha]_D^{25}$  56°, changing to -6° in 70 hrs. in presence of mineral acid or more slowly in neutral soln. (-12° in 300 hrs.). The rotation of the Na salt of II depends markedly on the  $p_H$  value of the soln. I may be regenerated from II by reduction with EtOH-I or H<sub>2</sub>S, when freshly prepd.; with the equil. mixt. H<sub>2</sub>S gives only 6% I but HI gives 75-80% I. I and PhNHNH<sub>2</sub> give the compd. C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>Na, deep red, m. 187° (decompn.); if the red soln. is cooled rapidly, the amorphous product m. 204°; *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>NHNH<sub>2</sub> gives the bright red compd., C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>Na, m. 202° (decompn.); *p*-BrC<sub>6</sub>H<sub>4</sub>NHNH<sub>2</sub> gives the dark red compd., C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>NaBr, m. 170° (decompn.); 2,4-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NHNH<sub>2</sub> gives the brownish red compd., C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>Na, m. 282° (decompn.). II and PhNHNH<sub>2</sub> give products m. 210° (yellow) and 216° (orange), having approx. the same compn.; the compd. from *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>NHNH<sub>2</sub>, light red, m. 280°, or yellow, m. 240°; from *p*-BrC<sub>6</sub>H<sub>4</sub>NHNH<sub>2</sub>, yellowish red, m. 220°, or yellow, m. 208°; from 2,4-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NHNH<sub>2</sub>, light red, m. 268° or 280° (all melt with decompn.). *o*-Tolylendiamine and I give a pale yellow product, m. 115° (decompn.). Oxidation of I with acid KMnO<sub>4</sub> and methylation of the product gives *Me trimethyl-l-threonate*, b<sub>10</sub> 120°,  $n_D^{20}$  1.4275,  $[\alpha]_D^{25}$  49° (MeOH, c 2.9), 31° (H<sub>2</sub>O, c 1.3), d<sub>15</sub> 1.090; *trimethyl-l-threonamide* (III), m. 78°,  $[\alpha]_D^{25}$  44° (H<sub>2</sub>O, c 1), 68° (MeOH, c 0.8). Oxidation of I with I and alk. HOI, esterification and methylation finally gives a sirup, b<sub>10</sub> 135°,  $[\alpha]_D^{25}$  49° (MeOH, c 1),  $n_D^{20}$  1.4270; from this was prepd. III and *trimethoxy-l-threonamide*, m. 255°. Oxidation of I with HOCl and then with HNO<sub>3</sub> and methylation gives Me oxalate and Me *d*-dimethoxysuccinate; the latter was characterized as the amide and methylamide. I and CH<sub>3</sub>N<sub>3</sub> give dimethylascorbic acid (IV),  $[\alpha]_D^{25}$  27° (H<sub>2</sub>O, c 1.5), is not oxidized by I, does not reduce Fehling soln., is unchanged on heating with 0.1 N H<sub>2</sub>SO<sub>4</sub> for 30 min. at 65°. With MeI and Ag<sub>2</sub>O IV gives *tetramethylascorbic acid* (V), b<sub>10</sub> 150°,  $n_D^{20}$  1.4690,  $[\alpha]_D^{25}$  0° (H<sub>2</sub>O), 2° (30% MeOH-H<sub>2</sub>O, c 6), 8° (50% MeOH-H<sub>2</sub>O, c 0.8); the action of O<sub>2</sub> in AcOH gives a neutral ester, which on hydrolysis and esterification, gives Me 3,4-dimethyl-l-threonate substituted in position 2 by a Me oxalate residue. MeOH-NH<sub>3</sub> gives oxamide and 3,4-dimethyl-l-threonamide with a small quantity of 3,4-dimethylerythronamide. *Me dimethoxymaleate* b<sub>10</sub> 85°,  $n_D^{20}$  1.4525.

C. J. West

**Synthesis of *d*- and *l*-ascorbic acid and of analogous substances.** R. G. Ault, D. K. Baird, H. C. Carrington, W. N. Haworth, R. Herbert, E. L. Hirst, E. G. V.

Percival, F. Smith and M. Stacey. *J. Chem. Soc.* 1933, 1419-23; cf. preceding abstr.—*d*- or *l*-Xylosone (0.35 g. from 10 g. xylosazone) with CaCl<sub>2</sub> and KCN gives *d*- or *l*-*ψ*-ascorbic acid, a sirup which exhibits a different absorption spectrum from that of I and gives rise to an osazone, m. 210°. With 8% aq. HCl at 40-50° there results *d*- or *l*-ascorbic acid (I), the *l*-form being identical with the natural I. These 2 steps give yields of about 70%. In the same way glucosone gives 3-*keto-d*-glucoheptonofuranolactone, m. 191°,  $[\alpha]_D^{25}$  14° (H<sub>2</sub>O, c 1), 22° (MeOH, c 1). The transformation of *d*-galacturonic acid into *l*-xylose phenyllosazone is outlined. C. J. West

**Reductive acid, a strongly reducing decomposition product from carbohydrates.** T. Reichstein and R. Oppenauer. *Helv. Chim. Acta* 16, 988-98 (1933).—Tetra-galacturonic acid-a (100 g.) from citrus pectin (cf. *C. A.* 24, 65), heated with 500 cc. 5% H<sub>2</sub>SO<sub>4</sub> in an autoclave at 150-5° for 1.5 hrs. gave 7 g. of yellow cryst. *reductive acid*, C(OH):C(OH).CO.CH<sub>2</sub>.CH<sub>2</sub>, m. 213-3.5°, be-

coming white on sublimation at 0.2 mm. and 150°. It is also obtained from pectin, xylose and galacturonic acid, but not from glucose, gluconic acid, furfural or hydroxymethylfurfural. It closely resembles ascorbic acid, reducing Fehling soln., AgNO<sub>3</sub>, acid I<sub>2</sub> soln. (reversibly), and dichlorophenol-indophenol in the cold, but has no antiscorbutic action. It forms a *Pb* salt, insol. in alc. and H<sub>2</sub>O; a *Na* salt, C<sub>5</sub>H<sub>7</sub>O<sub>4</sub>Na; a *mono-Me ester* (with C<sub>2</sub>H<sub>5</sub>Na), m. 138° (from C<sub>2</sub>H<sub>5</sub>); a *di-Me ester*, b<sub>12</sub> 120° (C<sub>2</sub>H<sub>5</sub>O); and a *phenyllosazone* (dihydrazone?), C<sub>7</sub>H<sub>9</sub>ON<sub>2</sub>, m. 247.5-8.5° (decompn.). It is oxidized by alk. KMnO<sub>4</sub> to succinic acid. M. P. Benoy

**Benzyl levulinate.** Peter P. T. Sah, Hsing Han Lei and Hsi Meng Fang. *J. Am. Chem. Soc.* 55, 4727-8 (1933).—Levulinic acid (52 g.), 160 g. PhCH<sub>2</sub>OH and 440 g. PhMe with dry HCl (7 g.), boiled 24 hrs., give 65 g. *benzyl levulinate*, b<sub>11</sub> 181-3°, d<sub>20</sub> 1.0935,  $n_D^{20}$  1.5000, *phenylhydrazone*, m. 91-2°; *p*-tolylhydrazone, m. 90-100°; *p*-chlorophenylhydrazone, m. 106-7°; *p*-bromophenylhydrazone, m. 103°. C. J. West

**Ester syntheses. I. New procedure for the rational preparation of esters.** Ernst Thielepape, with Alfred Fulde. *Ber.* 66B, 1454-60 (1933).—The method consists in the use of CaC<sub>2</sub> (to remove the water formed) in the thumb of a continuous extractor (*C. A.* 25, 4743). The prepn. of Et oxalate is complicated by the formation of Ca oxalate (from the Ca(OH)<sub>2</sub> formed by the water acting on the CaC<sub>2</sub>); to keep the Ca(OH)<sub>2</sub> away from the reaction flask it is therefore well to use a double thumb or a combination of 2 extractors, which precludes any possibility of the Ca(OH)<sub>2</sub> floating over into the reaction flask. Some substance (such as CCl<sub>4</sub>:CHCl, benzene, PhMe) is added which forms with the alc. and water a ternary mixt. of lower b. p. than the added substance itself. The best yields of Et oxalate (88-9%) were obtained with 45.0 g. anhyd. acid, 92.0 g. abs. alc. (twice the calcd. amt.), 50 g. CaC<sub>2</sub> and 150 cc. CCl<sub>4</sub>:CHCl, C<sub>6</sub>H<sub>6</sub> or PhMe boiled 14-18 hrs. in the combination app. (2 extractors combined). This equals the best yields recorded in the literature (Kenyon, *C. A.* 20, 46), and only 2 instead of 3.22 times the theoretical amt. of alc. is required. In fact, 74-7% yields were obtained by boiling 3.5 hrs. with only the calcd. amt. of alc. in CCl<sub>4</sub>:CHCl. The new method has been tried with a large no. of readily available acids, always with excellent results: *e. g.*, BzOEt, yield, 94.7%; Et malonate, 95.6%; Et succinate, 96.6%. Because the b. ps. of AcOEt (77°), EtOH (78°), CCl<sub>4</sub>:CHCl (87°) and C<sub>6</sub>H<sub>6</sub> (80°) lie so close together, the esterification of AcOH was carried out in ether in the presence of H<sub>2</sub>SO<sub>4</sub>; yield of AcOEt, 54.5% after boiling only 8 hrs. C. A. R.

**Reactivity of atoms and groups in organic compounds. XIV. Influence of substituents on the thermal stability of certain derivatives of malonic acid.** James F. Norris and Helen F. Tucker. *J. Am. Chem. Soc.* 55, 4697-704 (1933); cf. *C. A.* 26, 3229.—The temps. have been detd. at which a no. of substituted malonic acids first begin to show evidence of decompn. when they are heated so that

the temp. is increased at the rate of 2° per min. All the 12 monosubstituted products began to crack below the decompn. temp. of  $\text{CH}_3(\text{CO}_2\text{H})$ , (129°); the least effective group in lowering the cracking temp. was Ph (128°) and the most effective, *sec*-Bu (98°); the order of the primary alkyl groups was: Me, *iso*-Bu, Et, Bu, *iso*-Am, Pr, allyl. The introduction of a side chain in the  $\alpha$ -position increased to some extent lability toward heat of the C—C bond: Et 110°, *iso*-Pr 103°, Pr 99°, *sec*-Bu 98°, Me, Et 123°, Me, *iso*-Pr 110°; in the  $\beta$ -position there was decreased lability, Pr 99°, *iso*-Bu 115°; in the  $\gamma$ -position increase in lability, Bu, 108°, *iso*-Am 101°. All the 5 disubstituted malonic acids contg. 1 kind of radical which have been studied decomp. at higher temps. than the corresponding monosubstituted acid: Me, 150°, Et, 126°, Pr, 143°, (*iso*-Pr), 182°, (*iso*-Bu), 140°. All the disubstituted acids contg. 2 unlike radicals decomp. below the temp. of  $\text{CH}_3(\text{CO}_2\text{H})$ ; the most striking effect of lack of sym. on cracking temps. is the case of the Me-*iso*-Pr deriv. (110°). The order of the effect of the introduction of alkyl radicals into  $\text{MeCH}(\text{CO}_2\text{H})_2$ , as far as dectd., is the same as that obtained when these same radicals are introduced into  $\text{CH}_3(\text{CO}_2\text{H})_2$ . The order of the effect of the introduction of Et, Bu and Pr into  $\text{ClCH}(\text{CO}_2\text{H})_2$  is also the same. In  $\text{PhCH}(\text{CO}_2\text{H})_2$  (123°) the radical had less effect than Me on the lability toward heat of the C—C bond; introduction of Cl in the  $\alpha$ -position changed the cracking temp. from 123° to 102°;  $\text{PhCH}_2$  (115°) had a slightly greater stabilizing effect than Me (120°).  $\text{CH}_3(\text{CO}_2\text{H})_2$  can be held for at least 3 hrs. in a stream of air at 115–6° without the formation of  $\text{CO}_2$ ; at this temp. the time in min. required to produce a ppt. of  $\text{BaCO}_3$  was:  $\text{H}_2\text{O}$  3,  $\text{AcOH}$  3,  $\text{KHSO}_4$  5, Mg powder 8, Al powder 10,  $\text{ZnCl}_2$  10. When the acid was slowly heated with  $\text{CaO}$ ,  $\text{CO}_2$  was formed at 90°. C. J. West

Synthesis of diamond-like compounds. Hans Kleinfeller and Walter Frercks. *J. prakt. Chem.* 138, 184–206 (1933).—H. Decker (*Z. angew. Chem.* 37, 795 (1924)) has designated as "diamantoids" compds. those in which the at. arrangement within the mol. is that of the C atoms in the diamond lattice.  $\text{CHNa}(\text{CO}_2\text{Et})_2$  (3 mols.) and 60 g.  $\text{ONC}(\text{CH}_2\text{Cl})_2$  in EtOH, heated 18 hrs., give 40–5 g. of *tetra*-Et 1-chloro-2,2-diethylethylene-2<sup>1</sup>,2<sup>2</sup>,2<sup>3</sup>,2<sup>4</sup>-*tetra*-carboxylate (I),  $b_p$  165–7°; this also results from  $\text{ClCH}(\text{CH}_2\text{Cl})_2$ ; *tetra*hydrazide, with 1 mol.  $\text{H}_2\text{O}$ , m. 190°. With 4 mols.  $\text{CHNa}(\text{CO}_2\text{Et})_2$ , there results *hexa*-Et 3,3-diethyl-2-propene-1,1,3<sup>1</sup>,3<sup>2</sup>,3<sup>3</sup>,3<sup>4</sup>-*hexa*carboxylate, which could not be distd. I and EtOH-KOH give the free acid, m. 100°; above its m. p. it gives 1-chloro-2,2-diethylethylene-2<sup>1</sup>,2<sup>2</sup>-dicarboxylic acid, m. 92°. I and dry EtONa or Na, heated 8 hrs. at 170°, give a compd.,  $\text{C}_{12}\text{H}_{18}\text{O}_4\text{Cl}_2$ ,  $b_p$  151–61°, which splits off HCl on standing; *hydrazide*, m. 230° (decompn.). Hexahydrobenzylmalonic acid yields a *hydrazide*, m. 148°; neither the acid nor its ester reacts with EtONa.  $\text{CHNa}(\text{CO}_2\text{Et})_2$  (1 mol.) and 1 mol. 3,5,4- $\text{Br}_3(\text{AcO})\text{C}_6\text{H}_2\text{CH}_2\text{Br}$ , heated 18 hrs., give *di*-Et bis(3,5-dibromo-4-acetoxybenzyl)malonate, m. 117°; EtOH-KOH gives the 4-*HO* deriv., m. 142°; 3 mols.  $\text{CHNa}(\text{CO}_2\text{Et})_2$  and 1 mol. bromide give *di*-Et 3,5-dibromo-4-acetoxybenzylmalonate. *Di*-Et *p*-amino-benzylmalonate, citron-yellow, m. 64°; *HCl* salt, m. 120°; the *HCl* salt of the free acid m. 178°. *Di*-Et *p*-amino-hexahydrobenzylmalonate (II), m. 94°; *urea* deriv.,  $\text{C}_{14}\text{H}_{18}\text{O}_4\text{N}_2$ , m. 206–7°. Heating II *in vacuo* gives a compd., probably  $\text{H}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CH}(\text{CONHC}_6\text{H}_4\text{CH}_2\text{CH}(\text{CO}_2\text{Et}))_2$ . *Di*-Et *p*-hydroxyhexahydrobenzylmalonate, an oil which cannot be distd.; oxidation gives the *p*-keto deriv.,  $b_p$  150–67°, which gives with EtONa a compd., whose semicarbazone,  $\text{C}_{14}\text{H}_{18}\text{O}_4\text{N}_2$ , decomp. about 80°. C. J. West

Isomerization products of pyridine salts of unsaturated acids. O. Lutz, R. Klein and A. Jirgenson. *Ann.* 505, 307–10 (1933).—Fumaric acid (I) and  $\text{C}_6\text{H}_5\text{N}$  in MeOH, allowed to stand 4 weeks at room temp., give succinic acid pyridinium betaine, m. 192°; the  $\text{C}_6\text{H}_5\text{N}$  salt of I, heated at 140–5°, gives the same product. Crotonic acid and  $\text{C}_6\text{H}_5\text{N}$ , after several weeks or on heating at 75–160°, give the compd.  $\text{C}_{17}\text{H}_{18}\text{O}_4\text{N}$ , m. 79.5–80°; this is made

up of 8 mols. of acid (2 of which may be titrated) and 1 of  $\text{C}_6\text{H}_5\text{N}$ . No reaction occurs with  $\text{C}_6\text{H}_5\text{N}$  and aconitic, citraconic, meaconic, allylmalic and cinnamic acids.

Walden inversion. I. Dependence of the direction of reaction in the Walden inversion upon the number of free carboxyl groups. V. Anna Rao and P. C. Guha. *J. prakt. Chem.* 138, 167–83 (1933).—A review with 46 references, with special reference to Horton's rule.

C. J. West

Isoglutamine. Max Bergmann and Leonidas Zervas. *Z. physiol. Chem.* 221, 51–4 (1933).—The *l*(+)-isoglutamine prep'd. by Abderhalden and Nienburg (*C. A.* 27, 4778) and having a sp. rotation opposite to that of the B. and Z. prep'n. (*C. A.* 26, 5072) is shown to be not isoglutamine but the  $\text{NH}_4$  salt of *l*(–)-pyrrolidonecarboxylic acid. The mono-Et glutamate from which it was obtained was not the  $\alpha$ -ester,  $\text{HO}_2\text{CCH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{Et}$ , as supposed, but the  $\gamma$ -ester,  $\text{EtO}_2\text{CCH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$ , which readily undergoes ring closure.

A. W. Dox

Experiments on the production of urea from calcium cyanamide. F. G. Margolis. *Trans. Soc. Inst. Fertilizers* (Moscow) No. 92, 43–8 (1932).—Expts. are reported on the acid hydrolysis of  $\text{CaCN}_2$  with  $\text{H}_2\text{SO}_4$  as a catalyst for the production of urea. With  $\text{CO}_2$  as the neutralizing agent for  $\text{CaCN}_2$  the reaction proceeded most favorably at 40°. A higher temp. is conducive to the formation of dicyanodiamide. It is important to have the reaction go on fast; otherwise the  $\text{H}_2\text{CN}_2$  is converted into other less valuable products. The reaction was conducted with a 7–8% soln. of  $\text{H}_2\text{CN}_2$  with various addns. of  $\text{H}_2\text{SO}_4$ —from 2 to 40%. The optimum concn. of  $\text{H}_2\text{SO}_4$  was found to be 20% at a temp. of 75–86°. The product obtained was not hygroscopic and the yield was 85% of pure urea.

J. S. Joffe

Pseudohalides. XXIII. Reactions and tautomers of cyanates. Lothar Birckenbach and Hans Kolb. *Ber.* 66B, 1571–7 (1933); cf. *C. A.* 28, 59.—A satd. MeOH soln. of  $\text{KCNO}$  was electrolyzed at –15°. At the anode, added  $\text{C}_6\text{H}_{10}$  and  $\text{I}_2$  reacted to decolorize the  $\text{I}_2$  and give the Me 2-iodocyclohexylallophanate (I), m. 160.5°. Treatment of  $\text{Hg}(\text{OCN})_2 \cdot 2\text{KOAc}$  in MeOH at –50° with  $\text{C}_6\text{H}_{10}$  and  $\text{I}_2$  gave I, Me 2-iodocyclohexylcarbamate (II), m. 134–5°, and urethan. Urea by the Grignard reaction gave 2-iodocyclohexylurea, which with  $\text{ClCO}_2\text{Me}$  gave I. Et 2-iodocyclohexylallophanate, m. 171°. I refluxed with HCl gave 2-aminocyclohexano-4,5-oxazoline; *picrate* m. 202.5°; *HCl* salt, m. 138°; yield 5%. The major product, 30%, was 2-hydroxycyclohexylamine. Boiling I with  $\text{H}_2\text{O}$  gives Me 2-hydroxycyclohexylallophanate, m. 173.5°; *HCl* salt m. 183.5°. Treatment of  $\text{Hg}(\text{NCO})_2 \cdot 2\text{KOAc}$  with  $\text{C}_6\text{H}_{10}$  and  $\text{I}_2$  in MeOH at –15° gave iodomethylcyclohexanol and II, but no allophanate. Foster Dee Snell

Study of the effect of unsaturated aliphatic groups in barbituric acids. H. A. Shonle and John H. Waldo. *J. Am. Chem. Soc.* 55, 4649–52 (1933).—4-Chloro-2-pentene,  $b_{10}$  58°,  $n_D^{20}$  1.4311; 4-chloro-2-hexene,  $b_{10}$  73–6°,  $n_D^{20}$  1.4356; 3-bromohexane,  $b_{10}$  65.8–7°,  $n_D^{20}$  1.4469. Malonic esters: isocamyl propargyl,  $b_{10}$  142–51°,  $n_D^{20}$  1.4403–1.4409; 1-methyl-2-butenyl ethyl,  $b_{10}$  135–8°,  $n_D^{20}$  1.4418–1.4438; 1-ethyl-2-butenyl ethyl,  $b_{10}$  143–4.6°,  $n_D^{20}$  1.4437–1.4439; 1-ethylbutyl ethyl,  $b_{10}$  135–8°,  $n_D^{20}$  1.4363–1.4369; *sec*-butyl propyl,  $b_{10}$  122–4°,  $n_D^{20}$  1.4381–1.4382. Barbituric acids: *sec*-butyl propargyl, m. 167–8°; isocamyl propargyl, m. 163–4°; 1-methyl-2-butenyl ethyl, m. 114.5–6°; 1-ethyl-2-butenyl ethyl, m. 93–4°; 1-ethylbutyl ethyl, m. 112–5°; *sec*-butyl propyl, m. 136–8°. Alkanylethyl propargyl barbituric acids contg. the unsatd. *sec*. pentyl or hexyl group have less hypnotic action than corresponding barbituric acids with satd. alkyl groups and cause convulsions at low doses.\* The 2 propargyl deriva. have hypnotic action which was not more effective than the corresponding acids contg. the allyl or Pr group. Detailed results of physiol. effects will be published elsewhere.

C. J. West

\* Galactoseptajoses. II. Fritz Michael and Fritz

Sackfull. *Ann.* 587 p138-43(1933); cf. C. A. 27, 3453. —  $\alpha$ - or  $\beta$ -Pentaacetyl-galactoseptanose (I) and  $\text{TiCl}_4$  in  $\text{CHCl}_3$  give the same  $\beta$ -acetochlorogalactose  $< 1,6 >$ ,  $[\alpha]_D^{25} -79.5^\circ$  ( $\text{CHCl}_3$ );  $\text{Ag}_2\text{CO}_3$  in abs. MeOH gives  $\alpha$ -tetraacetylmethylgalactoseptanoside, m.  $108^\circ$ ,  $[\alpha]_D^{25} 17^\circ$  ( $\text{CHCl}_3$ ); hydrolysis gives  $\alpha$ -methylgalactoseptanoside,  $[\alpha]_D^{25} 26^\circ$  ( $\text{H}_2\text{O}$ );  $\text{Ag}_2\text{O}$  and MeI in MeOH give penta-methylgalactoseptanose, b.  $86^\circ$ , which is oxidized to tetramethylmucic acid; this establishes the above sugars as having a  $< 1,6 >$  ring. Acid sapon. of  $\beta$ -I gives galactopyranose, m.  $161^\circ$ ; MeONa gives the same product.

C. J. West

The behavior of hexoses with animal black and iron phosphate complexes. K. Wunderly. *Helv. Chim. Acta* 16, 1013-18(1933).—Neither  $d$ -fructose nor  $d$ -glucose is decompd. on heating in dil. aq. soln. in the presence of animal black, in an app. free from O. The sugars are also stable when the soln. contains  $\text{Ca}_3(\text{PO}_4)_2$ ,  $\text{Mg}_3(\text{PO}_4)_2$ ,  $\text{MgHPO}_4$  or a  $\text{Na}_2\text{HPO}_4\text{KH}_2\text{PO}_4$  buffer soln. ( $\text{pH}$  4.5-7.5). The addn. of alanine to  $d$ -fructose solns. yields fructose-alanine systems which are decompd. by heating in the presence of animal charcoal. By dissolving 2 g.  $\text{KFe}(\text{CO}_3)_2$  in 15 g.  $\text{H}_2\text{O}$  and decolorizing with 15 g.  $\text{Na}_2\text{P}_2\text{O}_7$  an acid- and alkali-stable complex is formed which can be buffered with  $\text{KH}_2\text{PO}_4$  and which promotes the decompn. of fructose-alanine systems in the absence of O.

C. R. Addinall

Ferric complex salts of aliphatic polyhydroxy compounds. Wilhelm Traube, Fritz Kuhner and Hans Harting. *Ber.* 66B, 1545-56(1933); cf. C. A. 26, 2170. Previous work was extended to include sugars and their acids. Barium-ferric glucose, mannose, mallose, lactose, saccharose, galactose, arabinose, glucose oxime, fructose oxime, mannose methoxime, gluconate, glycerate, erythrate, arabate and amygdalin were prepd. The corresponding sodium-ferric gluconate was prepd.,  $[\alpha]_D^{25} 176.3^\circ$ , as compared with Na gluconate,  $[\alpha]_D^{25} 10.3^\circ$ . Al and Cr were substituted for Fe in the prepn. of mannitol complexes. Me ethers of sugar oximes were prepd. by the action of  $\text{NH}_4\text{OMe}$  on the sugars: mannose methoxime m.  $117-8^\circ$ , galactose methoxime m.  $153^\circ$ ; arabinose methoxime m.  $120-1^\circ$ .

Foster Dee Snell

Rotatory dispersion of organic compounds. XXIII. Rotatory dispersion and circular dichroism of aldehydic sugars. H. Hudson, M. L. Wolfrom and T. M. Lowry. *J. Chem. Soc.* 1933, 1179-92; cf. C. A. 27, 5308.—Measurements are reported of the absorption spectrum, circular dichroism and rotatory dispersion of the acetates of the open-chain aldehydic  $\mu$ -forms of glucose, galactose and arabinose. These aldehydic sugars have a characteristic "carbonyl" absorption band at 2900 A. U., which is optically active and gives rise to a  $l$ -rotation in the visible spectrum. This band is either sym. on a scale of wave lengths or slightly steeper toward the visible spectrum. The "dissymmetry factor" ( $\epsilon_\gamma \sim \epsilon_\delta$ ), which measures the ratio of the circular dichroism to the absorption of unpolarized light, is approx. proportional to the frequency, but falls off slightly on the side of shorter wave lengths, although this anomaly is much less marked than with camphor and camphor- $\beta$ -sulfonic acid. The rotatory dispersion of these  $\mu$ -sugars includes (1) a  $l$ -rotation due to the induced dissymmetry of the aldehydic group, (2) a  $d$ -rotation, with a characteristic frequency in the Schumann region, which is attributed to the fixed asymmetry of the  $:\text{CHOAc}$  groups. With tetraacetyl- $\mu$ -arabinose, however, the Schumann terms cancel out and the whole of the observed rotation is due to the aldehydic groups. The partial rotation of the aldehydic group can be represented by the equation of Lowry and Hudson, which agrees with the exptl. data more closely than do the equations of Natanson and of Kuhn and Braun. The principle of optical superposition and the validity of Hudson's rules of isorotation are discussed in the light of the results obtained with the aldehydic sugars.

C. J. West

Hydrogenolysis of sugars. Walter M. Zartman and Homer Adkins. *J. Am. Chem. Soc.* 55, 4659-63(1933).

Glucose, sorbitol, mannitol, sucrose, lactose, maltose,  $\alpha$ -Me  $d$ -glucoside, pentaacetylglucose and gluconic lactone in EtOH undergo a rapid hydrogenolysis in the presence of  $\text{H}_2$  under 300 atm. pressure at  $260^\circ$  with a Cu-Cr oxide catalyst to give MeOH, EtOH, propane-1,2-diol and 3 addnl. compds. to which have been assigned the following tentative structures: 3-(4-hydroxytetrahydrofuryl)methylcarbinol, b.  $118-25^\circ$ ,  $d_4^{25} 1.1452$ ,  $n_D^{25} 1.4763$ ; hexane-1,2,6-triol, b.  $142-4^\circ$ ,  $d_4^{25} 1.1075$ ,  $n_D^{25} 1.4722$ ; and hexose-1,2,5,6-tetrol, b.  $214-5^\circ$ . The yields of higher-boiling products was materially increased by interrupting the hydrogenolysis after the absorption of 2-3 mols.  $\text{H}_2$ . No attempt is made to formulate the series of reactions involved in the formation of these products because there is no conclusive evidence on the basis of which a choice may be made between several alternatives. However, the formation of each of the products is understandable in consideration of the behavior of simpler glycols, aldehydes and ketones toward hydrogenolysis. C. J. West

Comparative ultraspectroscopic and analytical chemical studies on the splitting of sugars by alkalies. F. Fischler, H. Hauss and K. Tüfel. *Biochem. Z.* 265, 181-90(1933).—Sugars with a free carbonyl group which are split by alkali go through a 3-C phase in the process, and this is by all available evidence a methylglyoxal phase. Ultraspectroscopic studies likewise show that various sugars (glucose, galactose, mannose, xylose) under the influence of alkali give an absorption band in their spectrum which ranges from 2472 to 2845 A. U., indicating a similarity or even identity of the processes involved in all of them, dominated apparently by methylglyoxal whose absorption band is likewise 2400 to 2842 A. U.

S. Morgulis

Reducing sugars. IV. M. Gabryelski and L. Marchlewski. *Biochem. Z.* 265, 50-7(1933); cf. C. A. 27, 4218.—Glucose dissolved in a phosphate buffer of  $\text{pH}$  7.2 and heated to  $40^\circ$  begins to show a change in spectrum only after 192 hrs. when a band with max. absorption at 3655 A. U. appears. No change in the spectrum occurs when a glucose soln. is kept in a buffer of  $\text{pH}$  8.5 made up from glycine, NaCl and NaOH. Warming promotes the appearance of the characteristic band at 2670 A. U., which in 0.01 N NaOH at  $40^\circ$  comes in 17 hrs. whereas at room temp. only after 75 hrs. Lactose and maltose likewise in the presence of a sufficient OH-concn. ( $\text{pH} > 10$ ) give 3 characteristic bands with max. at 2635, 3100 and 3690 A. U. and 2682, 3116 and 4025 A. U., resp.

S. Morgulis

The assumed polyglucide formation in alkaline solutions of hexoses. H. A. Spoehr and Harold H. Strain. *Biochem. Z.* 264, 1-5(1933).—No polyglucide formation was found in solns. of  $d$ -glucose,  $d$ -fructose or  $d$ -galactose which were kept for 2 months in the dark at temps. of  $15.5-38^\circ$  in the presence of  $\text{Na}_2\text{CO}_3$ ,  $\text{Ca}(\text{OAc})_2$ ,  $\text{Pb}(\text{OAc})_2$  or  $\text{UO}_2(\text{OAc})_2$ .

S. Morgulis

$\beta$ -4-Glucosidolevoglucosan and 4-galactosidolevoglucosan. P. Karrer and J. C. Harloff. *Helv. Chim. Acta* 16, 962-8(1933).—Acetobromocellobiose (200 g.), treated with  $\text{Me}_3\text{NH}$  in  $\text{CHCl}_3$ , gives 38-40 g. heptaacetylcellobiosidodimethylamine, m.  $206^\circ$  (from alc.),  $[\alpha]_D^{25} -10.74^\circ$  ( $\text{CHCl}_3$ ). Thirty g. of this reacts with MeI in MeOH to give heptaacetylcellobiosidotrimethylammonium iodide (I) (26.7 g.),  $\text{C}_{28}\text{H}_{48}\text{O}_{11}\text{NI}$ , pptd. from alc. by  $\text{Et}_4\text{O}$ . I (25 g.), treated with  $\text{Ba}(\text{OH})_2$ , gives 3.5-4 g. hygroscopic  $\beta$ -4-glucosidolevoglucosan (II),  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ,  $[\alpha]_D^{25} -72.97^\circ$  ( $\text{H}_2\text{O}$ ). II, acetylated, gives the hexaacetate (III),  $\text{C}_{24}\text{H}_{38}\text{O}_{11}$ , m.  $144^\circ$  (from alc.),  $[\alpha]_D^{25} -46.24^\circ$  ( $\text{CHCl}_3$ ). Sapon. of III with  $\text{Ba}(\text{OH})_2$  gives again non-cryst. II, which is hydrolyzed by vineyard slug enzyme (from *Helix pomatia*), but not by emulsin, and after fermentation with yeast and acetylation of the residue, triacetyllevoglucosan (IV), m.  $110^\circ$  (from alc.), is obtained. Acetobromocellobiose (150 g.) gives similarly heptaacetylcellobiosidodimethylamine (32-5 g.), m.  $154^\circ$  (from alc.),  $[\alpha]_D^{25} -21.37^\circ$  ( $\text{C}_6\text{H}_6$ ). Thirty g. of this yields 27 g. heptaacetylcellobiosido-1-trimethylammonium iodide (pptd. from alc. with  $\text{Et}_4\text{O}$ ), 30 g. of which, heated with  $\text{Ba}(\text{OH})_2$ ,

gives 5-6 g. 4-galactosidomannosan (V), an oil becoming a hygroscopic solid on treatment with abs. alc.,  $[\alpha]_D^{25}$  -44.65 (H<sub>2</sub>O). On acetylation V gives the hexaacetate, m. 206° (from alc.),  $[\alpha]_D^{25}$  -38.89° (CHCl<sub>3</sub>). V is hydrolyzed by the slug enzyme, not by emulsin, and after fermentation and acetylation, the product m. 110° and is identical with IV. M. P. Benoy

The constitution of glucoses. F. Valentin. *Chem. Listy* 27, 275-8, 301-3, 319-25 (1933).—The constitution of sugars as polyhydroxy aldehydes, butylene oxides and arylene oxides is reviewed. The stable and unstable forms or their derivatives are discussed in connection with the semiacetal ring. Frank Maresch

Anhydride formation in 2,3,6-trimethylglucose. II. Kurt Hess and Otto Littmann. *Ann.* 506, 298-306 (1933); cf. C. A. 27, 3701.—The dimethylglucal obtained by the action of B<sub>2</sub>O<sub>3</sub>-HCl on trimethylcellulose and further action of Na is catalytically reduced to dihydrodimethylglucal, b<sub>m</sub> 66°,  $[\alpha]_D^{25}$  -16.39° (CHCl<sub>3</sub>), 0.20° (H<sub>2</sub>O); 4-*p*-toluenesulfonyl deriv., m. 73-4°,  $[\alpha]_D^{25}$  -8.72° (CHCl<sub>3</sub>); 4-*sym*-dinitrobenzoyl deriv., m. 172-3°,  $[\alpha]_D^{25}$  -14.95° (CHCl<sub>3</sub>), -69.07° (C<sub>6</sub>H<sub>5</sub>), -10.24° (Me<sub>2</sub>CO). The Na slime from the reduction of the Cl sugar contains a compd. b<sub>m</sub> 65-70°, with 27% OMe and some Ac, and another product, b<sub>m</sub> 65-70°, 29.9% MeO and 28.9% AcOH,  $[\alpha]_D^{25}$  7.35° (CHCl<sub>3</sub>). The action of mol. Ag upon the Cl sugar gives a compd. m. 75-80°,  $[\alpha]_D^{25}$  73.01° (C<sub>6</sub>H<sub>5</sub>), 78.28° (CHCl<sub>3</sub>), consisting largely of nonamethyltrihexosan. C. J. West

Synthesis of  $\alpha$ - and  $\beta$ -phenyl-*d*-mannoside. B. Helferich and S. Winkler. *Ber.* 66B, 1556-8 (1933).—The method of prep. Ph glucosides recently described (C. A. 27, 2680) is also applicable to mannose. Pentaacetyl-*d*-mannose (18 g.) with 11 g. PhOH and 1.1 g. anhyd. ZnCl<sub>2</sub>, heated 8 hrs. in the absence of moisture on the water bath, gives 0.34 g. of  $\beta$ -tetraacetylphenyl-*d*-mannoside, m. 160-70°,  $[\alpha]_D^{25}$  -62.74° ( $\beta$ -Ph *d*-mannoside, from the tetraacetate and a little NaOMe in boiling MeOH, m. 175-6.5°,  $[\alpha]_D^{25}$  -71.6° (H<sub>2</sub>O)), reduces only after hydrolysis with acids, and 3.2 g. of  $\alpha$ -tetraacetylphenyl-*d*-mannoside, m. 79-80°,  $[\alpha]_D^{25}$  73.9° (CHCl<sub>3</sub>) ( $\alpha$ -Ph *d*-mannoside, m. 132-3°,  $[\alpha]_D^{25}$  113.5° (H<sub>2</sub>O)). A somewhat better yield (30%) of the  $\alpha$ -compd. is obtained by heating equal parts pentaacetylmannose and PhOH with 0.05 part *p*-MeC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>H at 100°. C. A. R.

Synthesis of 2,3,4-trimethyl-*d*-galactose. Motoi Onuki. *Bull. Inst. Phys.-Chem. Research* (Tokyo) 12, 614-19 (1933).—With *d*-galactose (I) as starting material, 2,3,4-trimethyl-*d*-galactose (II), which is identical in phys. and chem. respects with the product obtained from methylated stachyose and methylated aldohexonic acid, has been synthesized in 2 different ways. I in anhyd. C<sub>6</sub>H<sub>5</sub>N and Ph<sub>3</sub>CCl give triphenylmethyl-*d*-galactose (III), m. 87-8°,  $[\alpha]_D^{25}$  5.08 (Me<sub>2</sub>CO), 0° (C<sub>6</sub>H<sub>5</sub>N); repeated methylation of III in pure MeOH with MeI and Ag<sub>2</sub>O results in 2,3,4-trimethyl-6-triphenylmethyl-*d*-galactoside (IV), m. 54-5°,  $[\alpha]_D^{25}$  -24.21 (alc.); on acetylation of II in anhyd. C<sub>6</sub>H<sub>5</sub>N with anhyd. AcOH, 1,2,3,4-tetraacetyl-trityl-*d*-galactose, m. 91-2°,  $[\alpha]_D^{25}$  -13.32 (Me<sub>2</sub>CO), is obtained. IV in CHCl<sub>3</sub> hydrolyzed with HCl gives 2,3,4-trimethylmethylgalactoside (V), m. 72°,  $[\alpha]_D^{25}$  24.00 (H<sub>2</sub>O); hydrolysis of V with 4% HCl at 92-8° forms II, m. 86°,  $[\alpha]_D^{25}$  151.66 (immediate detn.), 120.83 (after 24 hrs.) (H<sub>2</sub>O). On methylation of I,  $\alpha$ -Me galactoside (VI), m. 100-2°,  $[\alpha]_D^{25}$  176.47 (H<sub>2</sub>O), is formed; VI in C<sub>6</sub>H<sub>5</sub>N and Ph<sub>3</sub>CCl give 6-triphenylmethyl- $\alpha$ -methyl-*d*-galactoside (VII), m. 84-7°,  $[\alpha]_D^{25}$  3.86 (C<sub>6</sub>H<sub>5</sub>N); repeated methylation of VII in MeOH with MeI and Ag<sub>2</sub>O gives 2,3,4-trimethyl-6-triphenylmethyl- $\alpha$ -methyl-*d*-galactoside (VIII), viscous liquid,  $[\alpha]_D^{25}$  10.38° (alc.); VIII in CHCl<sub>3</sub> hydrolyzed with HCl, gives 2,3,4-trimethyl- $\alpha$ -methyl-*d*-galactoside, viscous liquid,  $[\alpha]_D^{25}$  112.50° (H<sub>2</sub>O); hydrolyzed with 4% HCl at 85-92°, II results. K. K.

Osmometric investigation of dilute solutions of polymeric carbohydrates. IV. Molecular weight of crystalline acetylcellulose. II. Kurt Hess and Max Ullmann. *Ann.* 504, 81-94 (1933); cf. C. A. 27, 3199.—The mol. wt. of cryst. acetylcellulose II depends greatly on the concn. of

the soln. Above 0.25% at 20° osmotic pressure is scarcely discernible, so that the colloidal state may be assumed. Between 0.25-0.19, 0.16-0.08% and 0.07-0.01%, the apparent mol. wt. corresponds to (C<sub>6</sub>)<sub>9</sub>, (C<sub>6</sub>)<sub>8</sub> and (C<sub>6</sub>)<sub>7</sub>, resp. Since the concn. interval in which a colloidal soln. passes into 1 with mols. of (C<sub>6</sub>)<sub>18</sub> is very narrow, one must assume a possible equil. between colloidal and cryst. phases, which is readily displaced in either direction by slight changes in concn. The changes (C<sub>6</sub>)<sub>18</sub>—(C<sub>6</sub>)<sub>9</sub>—(C<sub>6</sub>)<sub>7</sub> are even more definitely marked and in suitable concns. are functions of time. A 0.7% soln. corresponding to (C<sub>6</sub>)<sub>9</sub> may persist for days; warming 1 hr. at 50° and cooling to 20° gives the (C<sub>6</sub>)<sub>8</sub> stage; freezing and thawing gives the (C<sub>6</sub>)<sub>7</sub> stage again, gradually changing to (C<sub>6</sub>)<sub>9</sub>. Evapn. of (C<sub>6</sub>)<sub>9</sub> regenerates (C<sub>6</sub>)<sub>18</sub>, m. 280-5°,  $[\alpha]_D^{25}$  23° (CHCl<sub>3</sub>). The possibility of the (C<sub>6</sub>) stage is discussed. C. J. West

Experimental investigations concerning the depolymerization of polysaccharides. Endre Berner. *Tids. Kjem. Bergesen* 13, 6-10 (1933); cf. C. A. 27, 2429.—A short report on B.'s recent investigations concerning the reactions which take place when various polysaccharides are being heated in glycerol, HCONH<sub>2</sub>, or AcNH<sub>3</sub>. With inulin and glycogen, no depolymerization takes place but the substance undergoes a change of phys.-chem. nature and, during the subsequent treatment—pptn. with alc., etc.—adsorbs impurities, which will cause erroneous results by detns. of mol. wts. With starch and lichenin, the exptl. results lead B. to assume, in contrast to other investigators, that the degradation observed is analogous to a hydrolysis, a H atom from the HO group of the glycerol going to sat. the free valency of the O atom, while the rest of the glycerol mol. is bound to the C atom of the resp. degradation products.

H. C. M. Ingeberg  
Starch. IV. Tritosylstarch, ditosyl-6-iodostarch and tribenzoylstarch. Kurt Hess and Robert Pfleger. *Ann.* 507, 48-54 (1933).—Starch (5 g.), swollen in C<sub>6</sub>H<sub>5</sub>N (about 5 days at 18-20°) reacts with 120 g. *p*-HO<sub>3</sub>SC<sub>6</sub>H<sub>4</sub>-Me (the radical *p*-MeC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub> is named tosyl) in C<sub>6</sub>H<sub>5</sub>N at 18-20° in 9 days to give nearly quantitatively a tritosyl deriv. (I), decomps. 235-40°, insol. in ordinary org. solvents. At higher temps. the product contains 2 tosyl groups and 1 Cl atom. Results of 9 expts. are given. I (9.2 g.) and 21 g. NaI in 80 cc. Me<sub>2</sub>CO, heated 3 days at 100°, give 96% of ditosyl-6-iodostarch (II), which is not homogeneous; in 1 expt. 6 g. I gives 2.85 g. Me<sub>2</sub>CO-sol. and 2.05 Me<sub>2</sub>CO-insol. II, while in another expt. there resulted 5.15 g. Me<sub>2</sub>CO-sol. and 0.2 g. Me<sub>2</sub>CO-insol. AgF in C<sub>6</sub>H<sub>5</sub>N gives a product with 1-4% I. Starch, swollen in C<sub>6</sub>H<sub>5</sub>N, and BzCl, shaken 12 days, give a tri-*Bz* deriv. in nearly quant. yield. V. Degradation of tritosylstarch and ditosyl-6-iodostarch with hydrobromic acid-acetic acid. Kurt Hess, Otto Littmann and Robert Pfleger. *Ibid.* 55-61.—Tritosyl starch and HBr in AcOH give 78.7% of 1- $\alpha$ -bromotritosylacetylhexose, m. 162°,  $[\alpha]_D^{25}$  113.1° (CHCl<sub>3</sub>), 101.6° (Me<sub>2</sub>CO); shaking with Ag<sub>2</sub>CO<sub>3</sub> in MeOH gives 81.6% of a tritosylacetyl- $\beta$ -methylhexoside (I), m. 131-2°,  $[\alpha]_D^{25}$  -12.85° (CHCl<sub>3</sub>), -4.03° (Me<sub>2</sub>CO), -32.12° (C<sub>6</sub>H<sub>5</sub>). I and NaI in Me<sub>2</sub>CO, heated 25 hrs. at 130°, give a compd. analyzing approx. for a diiodotosyl deriv., m. 228°. Ditosyl-6-iodostarch and HBr in AcOH give 85.1% of 1- $\alpha$ -bromoditosylacetylhexoside (II), yellow, amorphous powder,  $[\alpha]_D^{25}$  114.7° (CHCl<sub>3</sub>); Ag<sub>2</sub>CO<sub>3</sub> in MeOH gives 76.6% of a ditosylacetyl- $\beta$ -methylhexoside (II), m. 162-3°,  $[\alpha]_D^{25}$  10.62° (CHCl<sub>3</sub>), 4.81° (Me<sub>2</sub>CO), -17.74° (C<sub>6</sub>H<sub>5</sub>); AgF in C<sub>6</sub>H<sub>5</sub>N, shaken 40 hrs., gives ditosylacetyl- $\beta$ -methylhexoside, m. 79-80°,  $[\alpha]_D^{25}$  -42.25° (Me<sub>2</sub>CO), -23.67° (C<sub>6</sub>H<sub>5</sub>), -24.18° (CHCl<sub>3</sub>); catalytic reduction gives the desoxy deriv., m. 133-4°,  $[\alpha]_D^{25}$  -9.35° (CHCl<sub>3</sub>), -9.90° (Me<sub>2</sub>CO), -41.35° (C<sub>6</sub>H<sub>5</sub>). C. J. W.

Composition of pure inulin. P. Ohlmeyer. *Pharm. Monatsh.* 14, 158 (1933).—Pure inulin upon hydrolysis yields, besides fructose, small amts. of an aldose. The possibility of a rearrangement of free *D*-fructose in glucose in an acid medium is mentioned. The fermentation hydrolysis of polysaccharides with inulinase from *Asper-*

*gillus niger* makes this rearrangement improbable since it is accomplished at a minimal acidity of  $pH$  6.0. With pure inulin the hydrolysis is quant. Glucose is exactly detd. by crystn. of the major portion of the fructose (92%) from MeOH sirup and the mother liquor examd. Difference titration and optical rotation show as much as 1.5% glucose. Calcn. shows an inulin mol. of approx. 70 hexose combinations. H. M. Burlage

**Steric hindrance.** VIII. Julius v. Braun and Ernst Anton with Charlotte Kemény. *Ber.* 66B, 1873-8 (1933); cf. *C. A.* 27, 1813.—In the study of naphthenic acids, in which the  $CO_2H$  groups are converted into  $NH_2$  and the  $NH_2$  compds. are degraded, through the corresponding methoxyhydroxides, into olefins which are then oxidized (*C. A.* 26, 2306), the question has often arisen whether a sepn. of isomers, which cannot be effected with the naphthenic acids themselves, might not be effected with the amines formed in the 1st stage of the process. It seemed possible that, as the result of steric hindrance, acyl derivs. of the amines would show a difference in the ease with which they are sapon. To test this possibility, expts. have been conducted on the Bz derivs. of cyclopentylmethylamine (I),  $\beta$ -cyclopentylethylamine (II), (2,3,3-trimethylcyclopentyl)methylamine (III), (2,2,3-trimethylcyclopentyl)methylamine (IV) and (1,4,5,5-tetramethylcyclopentyl)methylamine (V). Under optimal conditions (4 hrs. heating with 4 parts of 38% HCl at  $120^\circ$ ) the amt. of each of the above Bz derivs. remaining unhydrolyzed was, resp., 45, 20, 70, 85 and 100%. The difference between II on the hand and IV and III on the other is so great that a practicable sepn. of bases of the type VI from those of types VII and VIII seems very probable; e. g., an amine mixt. consisting of 50% of bases of type VI and 50% of those of types VII and VIII would, after 1 hydrolysis, give a mixt. of Bz derivs. contg. 80% of type VI and 20% of types VII and VIII; a 2nd hydrolysis would change the ratio to 94:6, a 3rd to 98.5:1.5. The values found for IV and III make the prospect of sepn. of individual bases of type VI less hopeful, nor did the chlorides corresponding to the above amines show more promising differences in the reactivity of the halogens. I was obtained in over 90% yield from cyclopentylacetic acid with  $HN_3$  in  $CHCl_3$ . The Bz deriv., m.  $75^\circ$ ,  $b_p$   $185^\circ$ , gives with  $PCl_5$  cyclopentylmethyl chloride (IX),  $b_m$   $60^\circ$ , which reacts quite sluggishly, 70% being recovered unchanged after heating 2 hrs. with  $NH_4Et$ , piperidine, etc.; with  $PhONa$  in alc., the extent of reaction is no greater. II, from IX converted into the cyanide and reduced with Na and alc. (yield, 70%), b.  $158-9^\circ$ ; HCl salt, very hygroscopic, m.  $195^\circ$ ; picrate, m.  $142^\circ$ ; Bz deriv.,  $b_p$   $184^\circ$ , m.  $62^\circ$ , converted by  $PCl_5$  into  $\beta$ -cyclopentylethyl chloride (80% yield),  $b_m$   $84-6^\circ$ . III (dihydro- $\beta$ -campholenamine or dihydroisolaurenamine) forms a Bz deriv.,  $b_p$   $184^\circ$ , m.  $50^\circ$ , giving with  $PCl_5$  50% of the methyl chloride,  $b_m$   $70-8^\circ$ , which hardly reacts with piperidine, etc. IV (over 90% from isocampholic acid with  $HN_3$ ),  $b_p$   $71-3^\circ$ ; picrate, darkens  $205^\circ$ , decomps.  $222^\circ$ ; HCl salt, does not crystallize readily; chloroplatinate, becomes discolored and slowly decomps. from  $245^\circ$  up; Bz deriv.,  $b_p$   $185^\circ$ , m.  $92^\circ$ , gives with  $PCl_5$  an imide chloride which  $b_p$   $150-2^\circ$  without decompn.,  $b_m$   $180^\circ$  practically unchanged, but on distn. under atm. pressure (at  $170-220^\circ$ ) gives approx. 50% of the methyl chloride,  $b_m$   $60^\circ$ , in which the reactivity of the Cl is very slight; the corresponding bromide, from the Bz deriv. of the amine with  $PBr_3$ ,  $b_m$   $78^\circ$ . The Bz deriv. of V m.  $98^\circ$ ; the methyl chloride obtained with  $PCl_5$  readily loses HCl so that the product,  $b_m$   $84-86^\circ$ , which is obtained contains about 10.5%  $C_{10}H_{18}$  (X),  $b_m$   $54-5^\circ$ ,  $b_p$   $175^\circ$ ,  $d_4^{20}$  0.8441, into which it is completely converted by aq. alc. KOH. By exhaustively methylating with  $Me_2SO_4-NaOH$ , converting the product with KI into the quaternary iodide,  $C_{11}H_{22}NI$ , decomps.  $310-12^\circ$ , then, through the quaternary base, into the tertiary amine,  $C_{11}H_{21}N$ ,  $b_p$   $91^\circ$ ,  $d_4^{20}$  0.8804,  $[\alpha]_D^{20}$   $72.8^\circ$  (picrate, m.  $176^\circ$ ), and distg. the amine in  $CO_2$  with sirupy  $H_3PO_4$ , there is obtained a hydrocarbon  $C_{11}H_{20}$ ,  $b_m$   $154-7^\circ$ ,  $d_4^{20}$  0.8153,  $n_D^{20}$  1.4848, which is certainly different from

X, but it remains an open question whether or not the 2 substances are homogeneous or mixts.

C. A. R.

**Constitution of jasmone.** W. Treff and H. Werner. *Ber.* 66B, 1521-7 (1933).—From 450 g. of a fraction  $b_p$   $70-120^\circ$ ,  $d_4^{20}$  0.990, of the ethereal oil obtained from an ext. of jasmine flowers was isolated 134 g. of the semicarbazone, m.  $204-6^\circ$ , of Hesse's jasmone (I),  $C_{11}H_{16}O$  (*Ber.* 32, 2617 (1899)), which yielded 100 g. I,  $b_p$   $108-10^\circ$ ,  $d_4^{20}$  0.9467,  $[\alpha]_D^{20}$   $\approx 0^\circ$ . Hydrogenation of I according to Skita gave a tetrahydro deriv. (II),  $b_p$   $91^\circ$ ,  $d_4^{20}$  0.8850,  $n_D^{20}$  1.44877, whose semicarbazone m.  $165-6^\circ$  (if the hydrogenation is carried out in neutral soln. there is also obtained an isomeric semicarbazone, m.  $191-2^\circ$ ; the ketone liberated from the latter gives the former when treated with semicarbazide in AcOH). II, which gives caproic, levulinic and a keto acid  $C_{11}H_{20}O_3$  (semicarbazone, m.  $111-12^\circ$ ) with 2% aq.  $KMnO_4$ , is identical with Staudinger and Ruzicka's tetrahydropyrene (3-methyl-2-amyl-1-cyclopentanone) (*C. A.* 18, 1820) and was synthesized by condensing  $AmCH(CO_2Et)_2$  with  $Me_3CHCH_2CH_2CO_2Et$ , sapon. the resulting *tri-Et* tri-carboxylate (18% yield),  $b_p$   $180-4^\circ$ ,  $d_4^{20}$  1.015, converting the free acid into the dicarboxylic acid and distg. the dry Ba salt of the latter; yield of II, 45%. Dihydrojasmone, from I according to Paal,  $b_p$   $101-2^\circ$ ,  $d_4^{20}$  0.9201,  $n_D^{20}$  1.48107, is identical with S. and R.'s synthetic 3-methyl-2-amyl-2-cyclopenten-1-one. As I with 1%  $KMnO_4$  gives levulinic acid,  $EtCO_2H$  and, in all probability, AcOH but no  $PrCO_2H$ , succinic or glutaric acid, I can be only 3-methyl-2-(2'-pentenyl)-2-cyclopenten-1-one,  $CO_2CH_3$ .

$CH_3 \cdot CMe \cdot CCH_2CH:CHEt$ , the 1st monocyclic 5-

membered ring compd. found in ethereal oils. C. A. R.

The action of aluminum bromide on benzene. Eugen Wertyporoch and Hans Sagel. *Ber.* 66B, 1306-12 (1933).—A mixt. of 5.65 l. of  $C_6H_6$  with 800 g. of  $AlBr_3$  was divided among 4 desiccators and allowed to stand for 20 weeks at  $20^\circ$ . The HBr evolved—about 10% calcd. on the basis of  $C_6H_6$ —was absorbed with NaOH and  $P_2O_5$ . The liquid, bright yellow at first, turned brown gradually with sepn. of an oily deposit. The  $C_6H_6$  layer was sepd. from the lower oily layer and decompd. with ice. After removal of the  $AlBr_3$  remaining (about 1%), the  $C_6H_6$  was distd. off. The residue, distd. *in vacuo*, gave the following fractions: (1) 34.8 g. of a transparent liquid,  $b_p$   $51-2^\circ$ ,  $b_m$   $48^\circ$ , contg. 2 OH groups and having the compn.  $C_7H_{12}O_2$ ; (2) 21.3 g. of phenylcyclohexane (I),  $b_p$   $85-7^\circ$ ,  $b_m$   $105^\circ$ ; (3) 3.5 g. of a solid, found to be a mixt. of Ph<sub>2</sub> (II) and diphenylcyclohexane (III). The dark brown oily layer was stirred with 1.5 kg. of ice and extd. with 3 l. of  $Et_2O$  in small portions. The  $Et_2O$  soln. was red, with blue fluorescence. After removal of the  $Et_2O$  the residue (143 g.) was distd. *in vacuo*, giving the following fractions: (1) 1.5 g. of PhOH,  $b_p$   $21-2^\circ$ ; (2) 10 g. of a red-violet liquid,  $b_p$   $55-50^\circ$ , from which crystals sepd. on standing a few weeks (the crystals m.  $178-8^\circ$ , and consisted of a phenylcyclohexanediol with both OH groups in the cyclohexane nucleus. The red-violet liquid is a phenylcyclohexanol); (3) 33.5 g. of a thick yellow oil,  $b_p$   $144-50^\circ$ ,  $b_m$   $168-70^\circ$ , found to be a difficultly separable mixt. of phenylated methylcyclopentanes and phenylated cyclohexanes (chiefly derivs. of II); and (4) 24.0 g. of a brown resin, which is a mixt. of hydrocarbons.  $AlCl_3$  (80 g.) with 800 cc. of  $C_6H_6$  at  $30^\circ$  gave only the

oily layer contg. products similar to those obtained with  $\text{AlBr}_3$ . When large quantities of  $\text{AlBr}_3$  or  $\text{AlCl}_3$  act on  $\text{C}_6\text{H}_6$ , the H of the  $\text{C}_6\text{H}_6$  in the oily layer formed is so loosened that it can hydrogenate; the Ph residue set free can unite to give II and higher hydrocarbons. W. and S. are uncertain whether the primary product of the reaction is II or I. On longer reaction I is converted into III, which is in equil. with phenylated methylcyclopentanes, the main reaction product. The formation of O-contg. substances in these expts. proves that in a slow reaction the  $\text{O}_2$  of the air is so activated by  $\text{AlBr}_3$ , that even di-OH derivs. can be formed. Louise Kelley

**Poly-membered ring systems.** I. Synthesis of polymethylene ketones with more than six-membered rings. K. Ziegler, H. Eberle and H. Ohlinger. *Ann.* 506, 94-130 (1933).— $\text{MeCN}$ ,  $\text{LiPh}$  and  $\text{Et}_3\text{NH}$  at  $-10^\circ$  with decompn. of the reaction product with  $\text{H}_2\text{O}$  give 86% of  $\text{AcCH}_2\text{CN}$ ; similarly,  $\text{PrCN}$  gives 71.5% of  $\alpha$ -butyrylbutyronitrile (I),  $b_p$  96°; hydrolysis with 70%  $\text{H}_2\text{SO}_4$  gives 68%  $\text{Pr}_2\text{CO}$ .  $\text{PrCN}$  and  $\text{LiNPhEt}$  give 90% I. Sebacoitrile and  $\text{LiNEt}_3$  in concd. soln. give 13% of cyanocycloheptanone (II),  $b_p$  140-1° (semicarbasone, m. 163°); hydrolysis by concd.  $\text{H}_2\text{SO}_4$  or 48%  $\text{HBr}$  gives a poor yield of suberone. In more dil. solns. the yield is increased to 71%. II is hydrolyzed by  $\text{NaOH}$  to the Na salt of sebacoheptaminitrile. A 90% yield of II is obtained with  $\text{LiNPhEt}$ . Azelanitrile (30 g.) gives 9 g. of cyanocyclooctanone,  $b_p$  158-60°, m. 55-6° (semicarbasone, m. 161°), and 2,9-dicyano-1,8-diketocyclohexadecane, m. 171°, hydrolyzed to 1,8-diketocyclohexadecane. 1,14-Dicyanotetradecane and  $\text{LiNEt}_3$  and subsequent hydrolysis with 20%  $\text{H}_3\text{PO}_4$  give dicyanodisimidocycloheptadecanone, and cyanocyclopentadecanone, m. 142°; hydrolysis gives cyclopentadecanone,  $b_p$  120°. Cyanocycloheptadecanone, m. 108-9°, gives on hydrolysis cycloheptadecanone. Tetraiscotane-1,17-dione, m. 84°. C. J. West

**Catalytic high-pressure hydrogenation of aromatic hydrocarbons and catalytic high-pressure destruction of the corresponding hydrogenated products.** II. Mesitylene. III. Hexamethylbenzene. A. Dros, A. J. Tuleners and H. I. Waterman. *J. Inst. Petroleum Tech.* 19, 784-99 (1933).—Mesitylene\* was prepd. from  $\text{Me}_2\text{CO}$  and hydrogenated with the aid of Ni on kieselguhr at 240°, 217° and 148° with corresponding initial pressures of 140, 260 and 500 kg./sq. cm. The hexahydromesitylene formed, probably a mixt. of the *cis*- and *trans*-comps., was destructively hydrogenated. The fractions of the product were examd. as to d., n, solidifying point, etc. Hexamethylbenzene, from  $\text{Me}_2\text{CO}$  and  $\text{MeOH}$  by Reckleben and Scheiber's method, was hydrogenated to hexamethylcyclohexane, at a max. temp. of 319° and initial pressure of 143 kg./sq. cm. Destructive hydrogenation of this compd. at 472°, which temp. was held for 30 min., left considerable of the hexamethylcyclohexane unchanged. Emma E. Crandal

**Polyhalo derivatives of acetomesitylene.** II. Bromination of 3,5-dichloroacetomesitylene. C. Harold Fisher. *J. Am. Chem. Soc.* 55, 4594-7 (1933); cf. C. A. 27, 5726.—2,4,6- $\text{Me}_3\text{C}_6\text{H}_2\text{Ac}$  and Cl in  $\text{AcOH}$  give  $\alpha,\alpha,3,5$ -tetrachloroacetomesitylene (I), m. 108.5-7.5°; with Zn dust and  $\text{AcOH}$  there results 3,5-dichloroacetomesitylene (II), m. 107.5-9°. I or II and  $\text{NaOCl}$  in  $\text{C}_6\text{H}_5\text{N}$  give  $\alpha,\alpha,3,5$ -pentachloroacetomesitylene, m. 90-1°. The action of Br on II gives a mixt. of III and IV, m. 103.5-4.5°, which could not be sep'd. by crystn.; the same compd. results from equimol. amts. of III and IV from  $\text{EtOH}$ . II and  $\text{NaOBr}$  in  $\text{C}_6\text{H}_5\text{N}$  give  $\alpha,\alpha$ -tribromo-3,5-dichloroacetomesitylene (III), m. 84-5°. Two mols. Br and II in  $\text{AcOH}$  give  $\alpha,\alpha$ -dibromo-3,5-dichloroacetomesitylene (IV), m. 121-2°. C. J. West

**Rearrangements of polyenes.** VI. Tetrabiphenyldi-*tert*-butylethynylethane. June Chien-Yu Tsao and C. S. Marvel. *J. Am. Chem. Soc.* 55, 4709-13 (1933); cf. C. A. 27, 5072.—*tert*-Butylacetylene,  $(\text{PhC}_6\text{H}_5)_2\text{CO}$  and  $\text{EtMgBr}$  give 86% of *di*biphenyl-*tert*-butylethynylcarbinol (I), m. 172-6° (180-1° on block); rearrangement, with  $\text{H}_2\text{SO}_4$  in  $\text{AcOH}$  gives the unsubst. ketone,  $\text{Me}_2\text{C}-$

$\text{COCH}_2\text{C}(\text{C}_6\text{H}_5)_2$ , m. 144-5°. I and  $\text{PBr}_3$  in  $\text{Et}_2\text{O}$  give the bromide, m. 135-6°; with Ag there results the hydrocarbon  $\text{C}_{26}\text{H}_{24}$  (II), decomp. 135-48° (m. 166°, block); II also results from I and  $\text{TiCl}_4$  in  $\text{EtOH}$ . The Na compd. from the bromide and 40% Na-Hg did not yield cryst. products with  $\text{CO}_2$  or  $\text{CICl}_2\text{Me}$ ;  $(\text{Me}_2\text{BrC})_2$  at  $-80^\circ$  gives tetrabiphenyldi-*tert*-butylethynylethane (III), changing at  $0^\circ$  to II. II in boiling  $\text{C}_6\text{H}_5\text{Me}$  is slowly oxidized by  $\text{O}_2$  to give about 50% of  $(\text{PhC}_6\text{H}_5)_2\text{CO}$ . III is oxidized by  $\text{O}_2$  at  $-80^\circ$  to  $(\text{PhC}_6\text{H}_5)_2\text{CO}$ . C. J. West

**Action of elementary fluorine upon certain aromatic organic compounds under various conditions.** I. Lucius A. Bigelow, J. Herbert Pearson, Louis B. Cook and Wm. T. Miller, Jr. *J. Am. Chem. Soc.* 55, 4614-20 (1933).—Several procedures are described for reaction of F with various aromatic compds. and 2 types of metal app. have been designed for this purpose. The action of F on PhMe,  $\text{C}_6\text{H}_6$  and 12 derivs. of  $\text{C}_6\text{H}_5$  in  $\text{CCl}_4$  has been investigated and products contg. over 60% F have been isolated; a study has also been made of the action of F on a no. of derivs. of  $(\text{PhCH}_2)_2$  in  $\text{CCl}_4$ . Free F has been passed directly through certain org. liquids at temps. as high as 25° in the absence of any significant vapor phase; no violent reaction occurred under these conditions although free C was deposited. Definite compds. are not described. C. J. West

**Fluorination of organic compounds.** III. Action of fluorine on organic compounds. Wilhelm Bockemüller. *Ann.* 506, 20-59 (1933); cf. C. A. 25, 3642.—Hexadecane (10 g.) in 200 cc.  $\text{CCl}_4$  at 15°, treated with F- $\text{CO}_2$  (1:1) for 2 hrs., gives 14.7 g. of a mixt. of F derivs.,  $b_p$  104-12°, m. 7°; cyclohexane in  $\text{CCl}_4\text{F}$  at  $-80^\circ$  gives a F deriv., b. 100°; this is unchanged after boiling with  $\text{MeOH-KOH}$  for 5 hrs.  $\text{PrCO}_2\text{H}$  in  $\text{CCl}_4$  at  $0^\circ$  gives a mixt. of products, among which are the  $\beta$ - and  $\gamma$ -F derivs.,  $b_p$  80-98°; a *p*-phenylphenacyl ester, m. 92°, was isolated. The distn. residue contains succinic acid. With 2 N  $\text{NaOH}$  the mixed acids give butyrolactone and crotonic acid.  $\text{EtCHBrCO}_2\text{Et}$  (20 g.) and  $\text{AgF-CaF}_2$ , heated at 150°, give 8.6 g. of the  $\alpha$ -F deriv., b. 138-41°; the free acid  $b_p$  90°; the *p*-phenylphenacyl ester m. 91.5°. The same mixed F acids ( $\beta$ - and  $\gamma$ -) were obtained from  $\text{PrCOCl}$  and also from butyric acetic anhydride. Iso- $\text{PrCO}_2\text{H}$  and F give  $\beta$ -fluoroisobutyric acid,  $b_p$  80-2°.  $\text{Cl}_2\text{C:CCl}_2$  (I) (30 g.) and F at  $-80^\circ$  give 0.3 g.  $\text{Cl}_2\text{CCF}_2$ , 9.7 g. of  $\text{Cl}_2\text{FCCFCFCl}_2$ , 0.7 g.  $\text{Cl}_2\text{CCCl}_2\text{F}$  and 5.7 g. *di*-fluorooctachlorobutane (II),  $b_p$  139-42°; at  $0^\circ$ , 16.6 g. I gives 2.3 g. II. Hexadecene at 15° gives a small yield of the compd.  $\text{C}_{16}\text{H}_{32}\text{F}_2$ ,  $b_p$  103-6°. Oleic acid yields a compd.  $\text{C}_{18}\text{H}_{34}\text{O}_2\text{F}_2$ , m. 81°; in another expt., 2 isomers, m. 81° and 95°, were obtained. Elaidic acid gives a *di*-F deriv., m. 84-5°. Crotonic acid gives a liquid  $\alpha,\beta$ -difluorobutyric acid,  $b_p$  100-12°, a solid acid (III), m. 81°, and a residue analyzing for  $\text{C}_4\text{H}_4\text{O}_4\text{F}_4$ , whose di-*Me* ester  $b_p$  105-15°; sapon. of the ester with  $\text{MeOH-KOH}$  gives a compd.,  $\text{C}_4\text{H}_4\text{O}_4$ , m. 240-4° (decompn.). III with 2 N  $\text{NaOH}$  gives  $\alpha$ -fluorocrotonic acid, m. 112°. The action of F on  $\text{BzOH}$  in the presence of Br is also discussed, the compds.  $\text{C}_6\text{H}_5\text{FBr}$  and  $\text{C}_6\text{H}_5\text{F}_2\text{Br}$ ,  $b_p$  110-20° and 150-60°, resp., being analyzed. A special app. for the generation of F and a special fluorinating app. are described. C. J. West

**Nitration of benzotrichloride.** Peter P. T. Sah, Hsing-Han Lei and Tien-Hua Wang. *Science Repts. Natl. Tsinghua Univ.* A2, 137-41 (1933).—*m*-Nitrobenzoic acid is prep'd. by adding to 10 cc.  $\text{PhCCl}_3$  (purified by distn.) a mixt. of 4.4 cc. fuming  $\text{HNO}_3$  and 4.4 cc. concd.  $\text{H}_2\text{SO}_4$ , drop by drop, at 25-30°. It is then poured into  $\text{H}_2\text{O}$  at  $0^\circ$ , and the impure product dissolved in  $\text{NaOH}$ , rep'd. with dil.  $\text{HCl}$  and recrystd. from hot  $\text{H}_2\text{O}$  (yield 85%). 3,5-Dinitrobenzoic acid may be prep'd. by treating 10 cc. of  $\text{PhCCl}_3$  and 54 cc. concd.  $\text{H}_2\text{SO}_4$  with 9 cc. fuming  $\text{HNO}_3$ , drop by drop, at 25-30°, then heating on a water bath with addn. of 10 cc. more of fuming  $\text{HNO}_3$  for 1 hr., followed by heating at 185° for 1 hr. The product is cooled, poured into  $\text{H}_2\text{O}$  at  $0^\circ$ , and recrystd. This method is recommended for prep'g. the dinitro compd. on a lab. scale. Wm. H. Adolph

**Reactivity of the chlorine atom in the benzene nucleus.** Baman Bihari Dey and Yetchan Gunja Doraiswami. *J. Indian Chem. Soc.* 19, 309-20 (1933).—The relative influences of the  $\text{NO}_2$ ,  $\text{CN}$  and  $\text{CO}_2\text{H}$  groups on the reactivity of a Cl atom adjacent to each of these groups in an aromatic nucleus contrg. a  $\text{NO}_2$  group in addn. to the halogen atom and an activating group have been investigated by a study of the condensations of 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{Cl}$  (I), 2,4- $\text{NC}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Cl}$  (II) and 2,5- $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$  (III) with divers compds. The activating influence of the groups on the replacement of halogen by means of the aromatic amines decreases in the order  $\text{NO}_2 > \text{CO}_2\text{H} > \text{CN}$ . With  $\text{NaOMe}$  and  $\text{NaOEt}$  as well as with  $\text{NH}_4\text{Et}$  and urea the order becomes  $\text{NO}_2 > \text{CN} > \text{CO}_2\text{H}$ . It seems that, just as the order in which the different halogens are replaced depends upon the reagent used (*C. A.* 18, 674), so is the relative activating influence of the various neg. groups dependent largely on the nature of the reagents employed for substitution. Attempts to condense I, II and III with the Na derivs. of  $\text{CH}_3(\text{CO}_2\text{Et})_2$  (IV),  $\text{AcCH}_2\text{CO}_2\text{Et}$  (V),  $\text{NCCH}_2\text{CO}_2\text{Et}$ ,  $\text{MeNO}_2$  and  $\text{NCCH}_2\text{CONH}_2$  (VI) were only successful in the cases of I with IV and V, and I and II with VI. The difference in behavior of halo-2-nitro-4-cyanobenzene and of halo-2-cyano-4-nitrobenzene toward these reagents (*C. A.* 11, 959) as well as toward the aromatic amines is another example of the superior influence of the  $\text{NO}_2$  when adjacent to the halogen atom. The reduction of II (3 g.) with Sn and  $\text{HCl}$  gave 2 g. 4-chloro-3-cyanoaniline, m. 133° (stable to concd.  $\text{H}_2\text{SO}_4$ , concd.  $\text{HCl}$  and to boiling aq. and alc.  $\text{KOH}$ ); *Ac deriv.* m. 190°. Nitration of crude *o*- $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$  (20 g.) yielded 10-12 g. of III, m. 164°; *Me ester* (VII), m. 72°. By heating the components on the  $\text{H}_2\text{O}$  bath quant. yields of the condensation products of I with  $\text{PhNH}_2$  and *o*-, *m*- and *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , m. 158°, 118°, 160° and 135°, resp., were obtained. The condensation between II and  $\text{PhNH}_2$ , *m*- and *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$  by heating the substances together at 180° for 45-60 min. gave compds. m. 171°, 140° and 217°. II and *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$ , similarly treated, gave 2-cyano-4-nitro-4'-chlorodiphenylamine, m. 282°, but no condensation was effected with *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$  even when the components were heated at 200° for 2 hrs. When heated with  $\text{PhNH}_2$ , III yielded 2-anilino-5-nitrobenzoic acid, m. 250°, converted by heating with  $\text{PhNH}_2$  at 160° for 30 min. into 2-anilino-5-nitrobenzamide, m. 190°. The condensation of VII with  $\text{PhNH}_2$  gave *Me* 2-anilino-5-nitrobenzoate, m. 100°. With *o*-, *m*- and *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , III formed the corresponding 5-nitro-2-toluidinobenzoic acids, m. 254°, 256° and 262°, resp. By boiling alc.  $\text{NH}_4\text{Et}$  with I and II were formed 2,4-dinitrodiethylaniline, m. 81°, and 2-cyano-4-nitrodiethylaniline, m. 85°, then condensed with I to produce 2,4-dinitroaniline, m. 176°, and with II to give 2-uramide-5-nitrobenzamide, m. 198°, hydrolyzed by 15%  $\text{KOH}$  heated to boiling for 30 min. to 5-nitroanthranilic acid (VIII), m. 264°, and to 5-nitrosalicylic acid when boiled vigorously with 20%  $\text{KOH}$ . VIII was prepd. by nitrating acetylanthranilic acid and deacetylating the 5-nitroacetylanthranilic acid, m. 214°, by boiling with concd.  $\text{HCl}$  for 30 min. *o*-, *m*- and *p*- $\text{ClC}_6\text{H}_4\text{NO}_2$  did not react with urea. By refluxing I with  $\text{NaOEt}$  and  $\text{NaOMe}$  for 20-30 min. were formed 1-ethoxy- and 1-methoxy-2,4-dinitrobenzene, m. 86° and 89°. II similarly yielded 1-ethoxy- and 1-methoxy-2-cyano-4-nitrobenzene, m. 101° and 128°.  $\text{NaOEt}$  and *p*- $\text{ClC}_6\text{H}_4\text{NO}_2$  gave *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{OEt}$ , m. 57°, and a by-product, *p,p'*-dichloroazoxybenzene, m. 164°. No definite product could be isolated from attempts to condense  $\text{NaOEt}$  with *o*- $\text{ClC}_6\text{H}_4\text{NO}_2$ . By adding I to solns. of IV and V in alc.  $\text{NaOEt}$  and refluxing for 2-3 hrs., *di-Fl* 2,4-dinitrophenylmalonate, m. 52°, and Et 2,4-dinitrophenylacetate, m. 83°, were obtained.

C. R. Addinall

**Several reactions of *aci*-nitro salts and of fulminating silver.** Heinrich Wieland and August Hochtlen. *Ann.* 505, 237-47 (1933).—( $\text{PhCH}:\text{NO}_2$ ) $_2\text{Hg}$  and  $\text{Ph}_2\text{CCl}$  give 33% of *asym*-tetraphenylnitroethane, m. 169-70°. *aci*-Phenylnitroacetoneitrile Ag salt (I) (8 g.) and 5 g.  $\text{BzBzAg}$  give

5 g. of *benzoylphenylnitroacetoneitrile*, m. 118° (decompn.);  $\text{Ph}_2\text{CHBr}$  gives  $\alpha,\beta,\beta$ -triphenyl- $\alpha$ -nitropropionitrile, m. 146-7° (decompn.); 10%  $\text{MeOH-KOH}$  gives triphenylacrylic nitrile, m. 166-7°. I and  $\text{Ph}_2\text{CCl}$  give triphenylmethylphenyldiazomethane, m. 145° (decompn.) [decompn. in boiling  $\text{PhMe}$  gives ( $\text{Ph}_2\text{C})_2\text{O}$ ], tolan, a compd.,  $\text{C}_{14}\text{H}_{11}\text{ON}$ , m. 156-8° ( $\text{EtOH-KOH}$  gives an isomer, m. 182°), and  $\text{Ph}_2\text{CCNO}$ , m. 94.5°.  $\text{C}:\text{NOAg}$  and  $\text{BzBr}$  give ( $\text{BzNH}$ ) $_2\text{CO}$ ;  $\text{Ph}_2\text{CHBr}$  gives benzohydril cyanate, identified as the urea and the urethan, m. 129°. Benzohydroxamyl chloride and  $\text{C}:\text{NOAg}$  give in  $\text{C}_6\text{H}_5\text{N}$  a compd.,  $\text{PhC}:(\text{NOH})\text{C}_6\text{H}_5\text{N}\text{Cl}$ , with 1 mol.  $\text{EtOH}$ , m. 117°. In another expt. with a little  $\text{PhNMe}_3$ , there resulted a compd.,  $\text{C}_8\text{H}_5\text{O}_2\text{N}_3$ , m. 96-7° (decompn.), which may be phenylfuroxan. C. J. West

**The action of vanadium oxytrichloride upon various organic compounds.** R. E. Nelson and A. H. McFadden. *Proc. Indiana Acad. Sci.* 42, 119-22 (1933).— $\text{VOCl}_3$  was allowed to react with 16 org. compds. With some reaction occurred, with others colored solns. resulted while with others there was no evidence of reaction.  $\text{VOCl}_3$  and aniline gave a complexity of products. (One compd., m. 236°, was sol. in ether, alc.,  $\text{C}_6\text{H}_6$ , concd.  $\text{H}_2\text{SO}_4$ , and concd.  $\text{HNO}_3$ . An analysis showed the presence of C, N and H, but no V or Cl. Another compd. has been given the formula ( $\text{PhNH}$ ) $_2\text{V}:\text{O}$ .  $\text{VOCl}_3$  and  $\text{BzH}$  gave a grainy black ppt., which evolved  $\text{HCl}$ , even in a vacuum desiccator. The compd. to which has been given the formula ( $\text{OHCC}_6\text{H}_4$ ) $_2\text{V}$   $\text{Cl}_2$  upon hydrolysis yields  $\text{BzH}$  and  $\text{V}_2\text{O}_5$ . H. E. Messmore

**Firmness of attachment of organic residues.** IX. Julius v. Braun, Robert Michaelis, F. Fischer and R. Murjahn. *Ann.* 507, 1-13 (1933); cf. *C. A.* 26, 703. *p*-Ethoxybenzyl alc.,  $b_{12}$  134-5°; chloride,  $b_{10}$  95-100°, with *p*- $\text{MeOC}_6\text{H}_4\text{NHMe}$  it gives *p*-methoxybenzyl-*p*-ethoxybenzylmethylamine,  $b_{14}$  120-5°;  $\text{BrCN}$  gives a mixt. of *p*- $\text{MeOC}_6\text{H}_4\text{CH}_2\text{Br}$  and *p*- $\text{EtOC}_6\text{H}_4\text{CH}_2\text{Br}$ .  $\text{C}_6\text{H}_{11}\text{C}_6\text{H}_4\text{CH}_2\text{NHMe}$ ,  $b_{11}$  165°, forms a *HCl* salt, m. 186° (Pt salt, decomp. 215°). *Bis*(cyclohexylbenzyl)methylamine,  $b_{10}$  240°, m. 52° (methiodide, m. 196°) Phenylbenzyl(cyclohexylbenzyl)methylamine,  $b_{10}$  230-40°, m. 52-3° (methiodide, m. 200°), with  $\text{BrCN}$  there results a bromide intermediate in compn. between  $\text{PhC}_6\text{H}_4\text{CH}_2\text{Br}$  and  $\text{C}_6\text{H}_{11}\text{C}_6\text{H}_4\text{CH}_2\text{Br}$  and about equal amts. of  $\text{PhC}_6\text{H}_4\text{CH}_2\text{NMeCN}$  and  $\text{C}_6\text{H}_{11}\text{C}_6\text{H}_4\text{CH}_2\text{NMeCN}$ . *Bis*-phenylbenzyl(phenylbenzyl)methylamine, from  $\text{PhC}_6\text{H}_4\text{CH}_2\text{Cl}$ ,  $b_{11}$  165°, and  $\text{PhC}_6\text{H}_4\text{CH}_2\text{NHMe}$ , m. 186° (*HCl* salt, m. 245°);  $\text{BrCN}$  gives  $\text{PhC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{Br}$ ; the cyanamide is principally of the  $\text{PhC}_6\text{H}_4\text{CH}_2$  series *o*-ethylbenzylmethylamine,  $b_{12}$  92° (*HCl* salt, m. 108°); picrate, m. 139°. *o*-Phenylbenzylbenzylmethylamine,  $b_{12}$  223° (methiodide, m. 163°); *o*-ethylbenzyl deriv.,  $b_{12}$  173° (*HCl* salt, m. 174°; methiodide, m. 154°); *o*-ethylbenzyl-*o*-vinylbenzylmethylamine,  $b_{12}$  195-6° (*HCl* salt, m. 138°; methiodide, m. 164°); the bromides resulting from the action of  $\text{CNBr}$  are reported. *o*-Methylbenzylmethylamine,  $b_{11}$  100-2° (*HCl* salt, m. 150°; picrate, m. 129°), *o*-*Cl* deriv.,  $b_{10}$  98-100° (*HCl* salt, m. 135°; picrate, m. 120°); *o*-*I* deriv.,  $b_{10}$  130-2° (*HCl* salt, m. 180°; picrate, m. 150°); *m*-*Cl* deriv.,  $b_{11}$  122-4° (*HCl* salt, m. 170°; picrate, m. 128°); *m*-*Br* deriv.,  $b_{11}$  122° (*HCl* salt, m. 147°; picrate, m. 135°). *o*-Methylbenzyl-*p*-chloromethylamine, pale yellow,  $b_{10}$  180-4° (*HCl* salt, m. 170°; methiodide, m. 215°); *o*-chlorobenzyl-*o*-bromobenzylmethylamine,  $b_{10}$  150° (*HCl* salt, m. 160°; picrate, m. 129°); *o*-iodobenzyl deriv.,  $b_{10}$  200-3° (*HCl* salt, m. 200°); *o*-chlorobenzyl-*m*-iodobenzylmethylamine,  $b_{10}$  200°, m. 55-6° (*HCl* salt, m. 195°; picrate, m. 123°); *m*-chlorobenzyl-*p*-bromobenzylmethylamine,  $b_{10}$  186-90° (*HCl* salt, m. 187°); *p*-iodobenzyl deriv.,  $b_{10}$  210° (*HCl* salt, m. 202°; picrate, m. 110°); *m*-bromobenzyl deriv.,  $b_{10}$  180° (*HCl* salt, m. 210°; picrate, m. 147°); *m*-bromobenzyl-*m*-iodobenzyl methylamine,  $b_{10}$  200° (*HCl* salt, m. 194°; picrate, m. 140°); *o*-chlorobenzyl deriv.,  $b_{10}$  185° (*HCl* salt, m. 198°; picrate, m. 133°). The decompn. with  $\text{BrCN}$  shows that *m*- $\text{BrC}_6\text{H}_4\text{CH}_2$  takes a sharply defined middle position between *m*- $\text{ClC}_6\text{H}_4\text{CH}_2$  and *m*- $\text{IC}_6\text{H}_4\text{CH}_2$  and that *o*- $\text{BrC}_6\text{H}_4\text{CH}_2$  is between *o*- $\text{ClC}_6\text{H}_4\text{CH}_2$  and *o*-

$\text{IC}_6\text{H}_4\text{CH}_3$ . With chemically analogous substituents the position more than the mass affects the firmness of attachment. C. J. West

**Separation of *m*-xylydine from isomers with formic acid** B. I. Kissin *Anilinokrasochayaya Prom* 3, 80 (1933). The substitution of 50 and 85%  $\text{HCO}_2\text{H}$  for  $\text{AcOH}$  in the separ. of *m*-xylydine (I) from the mixt. of isomers is rendered impracticable by the formation of  $\text{C}_6\text{H}_4\text{Me}_2\text{NHC=O}$  at temps. above  $20^\circ$ , which is difficultly saponified, and by the contamination of I with the *p*-isomer which reacts with  $\text{HCO}_2\text{H}$  in similar manner. C. B.

**New azo dyes** A. Mironescu and I. V. Nicolescu *Bul. soc. chim. Romania* 15, 537 (1933). The following dyes were prepd. by use of the same general method with the appropriate deriv. of aniline in each case: *Na benzylideneaminoozobenzene p-sulfonate*,  $\text{NaO}_2\text{SC}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ , was prepd. by dissolving 19.1 g. sulfanilic acid in a soln. of 5 g.  $\text{NaOH}$  and 100 cc.  $\text{H}_2\text{SO}_4$ . The diazonium salt thus prepd. was dissolved in dil. alc.  $\text{KOH}$  and 5 g.  $\text{PhCH=NPh}$  in  $\text{AcOH}$  added. Upon making the soln. slightly alk. with  $\text{NaOH}$  the dye was pptd. Recrystd. from alc. at  $m. 76^\circ$ . *Na benzylideneaminoozobenzene p-sulfonate*,  $\text{NaO}_2\text{SC}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 157^\circ$ . *Na azobenzeneaminoozobenzene p-sulfonate*,  $\text{NaO}_2\text{SC}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 170^\circ$ . *p-Benzylideneamino p-nitrosoazobenzene-HCl*,  $\text{NO}_2\text{C}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 107^\circ$ . *Benzylideneaminohydroxyazobenzene-HCl*,  $\text{HOOC}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 175^\circ$ . *Bis-benzylideneaminophenyl diphenyl-HCl* (I),  $(\text{PhCH=NPh})_2\text{NHC=O}$ ,  $m. 107^\circ$ . *Benzylideneaminohydroxyazobenzene-HCl*,  $\text{HOOC}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 175^\circ$ . *Bis-benzylideneaminophenyl diphenyl-HCl* (I),  $(\text{PhCH=NPh})_2\text{NHC=O}$ ,  $m. 107^\circ$ . *Benzylideneaminohydroxyazobenzene-HCl*,  $\text{HOOC}_6\text{H}_4\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 175^\circ$ . All of these dyes are stable and dye wool, cotton and silk without mordant. W. A. Moore

**Constitution of *o*-hydroxyazo compounds** K. v. Arver *Ann.* 505, 299 (1933). A discussion of the constitution of hydroxyazo compounds especially the work of Purvis and Markwitsch. C. I. West

**Diazotization of very weakly basic amines** H. A. J. Schoutissen *J. Am. Chem. Soc.* 55, 1331 (1933). The method is based on the reaction of  $\text{H}_2\text{SO}_4$  to form an intermediate salt of the liberation of  $\text{HNO}$  from nitroxylic acid (I) by  $\text{HPO}_4$ . Thus, e.g.,  $2,4,6\text{-}(\text{ON})_2\text{C}_6\text{H}_2\text{NH}_2$  in 1 cc.  $\text{H}_2\text{SO}_4$  at  $0^\circ$  is treated with I from  $\text{NaNO}$  and 1 cc.  $\text{H}_2\text{SO}_4$  and then with 60 cc.  $\text{HPO}_4$  the diazotization proceeds quantitatively. In the same way  $2,4,6\text{-}(\text{ON})_2\text{C}_6\text{H}_2\text{NH}_2$  (II) gives 98% of *p*-dibromo-1-nitrobenzene,  $m. 15^\circ$ , the *o*-di-Cl deriv.  $m. 153^\circ$ . The diazo compd. from II and  $\beta\text{-C}_6\text{H}_4\text{OH}$  gives the azo dye  $\text{C}_6\text{H}_4(\text{ON})\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ , reddish brown with green metallic reflex,  $m. 221^\circ$ , the di-Cl deriv., red,  $m. \text{above } 270^\circ$ . The diazo compd. from picrochrome and  $\beta\text{-C}_6\text{H}_4\text{OH}$  gives a red dye,  $m. 200^\circ$ , or an azo dye, red with metallic reflex,  $m. \text{above } 260^\circ$  (decomps.).  $\text{PhOH}$  gives an azo dye  $\text{C}_6\text{H}_4(\text{ON})\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ ,  $m. 191^\circ$ , the dye from  $\text{PhOMe}$  (80% yield), orange,  $m. 14^\circ$ , from  $\text{PhOEt}$ , red with metallic luster,  $m. 171^\circ$ .  $2,4,6\text{-}(\text{ON})_2\text{C}_6\text{H}_2\text{NH}_2$ , diazotized and coupled with  $\text{PhOH}$ , gives a dye,  $\text{C}_6\text{H}_4(\text{ON})\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ , orange,  $m. 16^\circ$ .  $\text{PhOMe}$  gives a dye,  $\text{C}_6\text{H}_4(\text{ON})\text{N}=\text{NC}_6\text{H}_4\text{NHC=O}$ , red,  $m. 118^\circ$  (82% yield). The dye from  $5,2,4,6\text{-}(\text{ON})_2\text{C}_6\text{H}_2\text{NH}_2$  and  $\text{PhOH}$  is orange-red,  $m. 140^\circ$ . C. J. West

**Character of the diazonium group** Tetrazotization of *p*-phenylenediamine H. A. J. Schoutissen *J. Am. Chem. Soc.* 55, 1535 (1933). (1) C. 4, 16, 1220. By starting from the very negative character of the diazonium group and taking account of the fact that the reaction of diazotization proceeds between the salt of the amine and  $\text{HNO}$ , a logical and simple explanation is given why negatively substituted *p*-phenylenediamines could only be diazotized at 1 of the  $\text{NH}_2$  groups. Therefore the theoretical amine and of Morgan must be cast aside. *p*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  is quantitatively tetrazotized by the use of  $\text{H}_2\text{PO}_4$  and nitrosylsulfuric acid, with  $\text{KI}$  there results  $\beta\text{-C}_6\text{H}_4\text{I}_2$ , with  $\text{CuCl}$   $\beta\text{-C}_6\text{H}_4\text{Cl}_2$ , with  $\text{Br}$  in  $\text{KBr}$   $\beta\text{-C}_6\text{H}_4\text{Br}_2$ . *p*-Phenylenediamine sulfonic acid is tetrazotized in the same

way. Nitro-*p*-phenylenediamine, tetrazotized and treated with  $\text{KI}$ , gives 2,5-dinitrobenzene,  $m. 109-110^\circ$ . 1-iodo-2-nitrophenol, citron-yellow,  $m. 51^\circ$ , is a by-product. 2,5-Dichloro-*p*-phenylenediamine, treated with  $\text{CuCl}$  after tetrazotization, gives 61% of 1,2,4,5- $\text{C}_6\text{H}_2\text{Cl}_4$ , the 2,6-di-Cl isomer (I) gives 1,2,4,5- $\text{C}_6\text{H}_2\text{Cl}_4$ ,  $m. 80-81^\circ$ . 2,6-Dibromo-*p*-phenylenediamine gives 95% of 2,6-dibromo-*p*-diodobenzene,  $m. 115^\circ$ . I and  $\text{AcO}$  give a di- $\text{Ac}$  deriv.,  $m. 225^\circ$ ,  $\text{Ca}(\text{OCl})_2$  in  $\text{AcOH}$  gives the tri-Cl deriv.,  $m. 280^\circ$ , hydrolysis gives trichloro-*p*-phenylene diamine,  $m. 198^\circ$ , the diazo reaction gives  $\text{C}_6\text{H}_4(\text{NH})_2$  a tetrazotizable, however, different factors, as lesser stability of the tetrazo compd., coupling with products of decomposition and the formation of azimino compd., have an unfavorable influence on the yield. C. J. West

**Character of the diazonium group** New method of preparing mixed disazo dyestuffs H. A. J. Schoutissen *J. Am. Chem. Soc.* 55, 1541 (1933). The character of the diazonium group agrees with the influence of 2  $\text{NO}_2$  groups in the positions ortho and para with respect to the substituent. Tetrazotized  $\beta\text{-C}_6\text{H}_4(\text{NH})_2$  couples only with 1 mole of the azo component (both phenols and ethers) in strongly acid medium. The diazo azo compounds can be isolated by pouring into  $\text{H}_2\text{O}$  and may afterward be coupled with an azo compd. (not with ethers). Several examples are given. The compd. with  $\text{PhOMe}$  and  $\text{PhOH}$ ,  $\text{C}_6\text{H}_4(\text{ON})_2\text{N}_2$ , orange,  $m. 200^\circ$ , with  $\text{PhOH}$ , the compd.  $\text{C}_6\text{H}_4(\text{ON})_2\text{N}_2$ , greenish yellow,  $m. 171^\circ$ , is formed. C. J. West

**The formation of azides from *N*-nitroso derivatives of hydrazo compounds** G. Longo *Gazz. chim. ital.* 63, 165 (1933). The formation of hydrazoic acids from  $\text{RCOEt}$  compds. and  $\text{NH}_4\text{OH}$  (cf. *Ann.* 281, 169) suggested the prepn. of arylazohydrazoic acids,  $\text{ArN}(\text{NO})\text{NOH}$ , from  $\text{ArN}(\text{NO})\text{R}$  compds., and of arylhydrazohydrazoic acids,  $\text{ArNHNHC(OH)NOH}$ , from  $\text{ArNHNHCOR}$ . Attempts to accomplish this by first preping the  $\text{ArNHNHCOR}$  compds., forming  $\text{ArNHNHC(OH)NOH}$  compd. from these, and finally dehydrogenating to form  $\text{ArN}(\text{NO})\text{NOH}$  compd., failed under various conditions, as did further attempts by the use of  $\text{ArN}(\text{NO})\text{NH}_2$  and  $\text{ArNHNHCOR}$  compds. by the Hoffmann reaction (*Ber.* 22, 2854). Having prepd. the  $\text{ArNHNHCOR}$  compds., however, the behavior of their  $\text{ArN}(\text{NO})\text{NHCOR}$  derivs. with strong base was studied to ascertain why low yields of  $\text{ArN}_3$  compds. are obtained from them and from compds. in general with an  $\text{N}(\text{NO})\text{N}$  group like  $\text{ArN}(\text{NO})\text{NH}_2$  and  $\text{ArN}(\text{NO})\text{NHR}$  compds.,  $\text{ArN}(\text{NO})\text{NHCOR}$  compd. yield, when heated with strong bases, the corresponding azides. However, the yield is extremely low, and a simple cleavage is not the chief reaction. The formation of azide is preceded by the evolution of large quantities of  $\text{N}_2$ , which indicates that in alk. soln. the  $\text{NO}$  derivs. assume the tautomeric form,  $\text{ArN}(\text{N}=\text{O})\text{NCO R}$ , which contains a  $\text{N}=\text{N}=\text{N}$  group capable of eliminating  $\text{N}_2$ . To prep. the  $\text{ArNHNHCOR}$  esters, we cold  $\text{C}_6\text{H}_5\text{N}$  solns. of the  $\text{ArNHNHCOR}$  compds. were treated with  $\text{ClCO Me}$  or  $\text{ClCO Et}$  and poured into ice-cold  $20^\circ\text{C}$ .  $\text{H}_2\text{SO}_4$ . To prep. the  $\text{ArN}(\text{NO})\text{NHCOR}$  derivs., the ester in glacial  $\text{AcOH}$  were treated with excess concd. aq.  $\text{NaNO}$ . To prep.  $\text{ArN}(\text{NO})\text{NCO R}$  azo esters, the corresponding hydrazo compds. in glacial  $\text{AcOH}$  were treated with excess  $\text{CrO}_3$ , and poured into ice-water. These 3 syntheses gave the best results of any methods tried. *Me p-nitrophenylhydrazocarbonate* (I), yellow,  $m. 180^\circ$ . Its nitroso deriv.,  $\beta\text{-ONC}_6\text{H}_4\text{N}(\text{NO})\text{NHC(OH)Me}$ ,  $m. 125-6^\circ$ , treated in  $\text{Et}_2\text{O}$  with  $\text{PhIHNH}_2$  or in boiling water, it reverts to I. It is stable toward  $\text{NH}_4\text{OH}$ , in hot  $10^\circ\text{C}$ ,  $\text{NaOH}$  it yields approx. 43%  $\text{N}$  and 27%  $\beta\text{-ONC}_6\text{H}_4\text{N}_2$  (II). *Me p-nitrophenylazocarbonate*, orange-red,  $m. 84.5^\circ$ , stable toward  $\text{NH}_4\text{OH}$ . *Et p-nitrophenylhydrazocarbonate* (III), brown-yellow,  $m. 198.9^\circ$ , stable toward  $\text{NH}_4\text{OH}$ . Its nitroso deriv., brown-yellow,  $m. 110-1^\circ$  (decomps.), in boiling water or with  $\text{PhIHNH}_2$ , it reverts to III, in boiling dil.  $\text{NaOH}$  it evolves  $\text{N}$  and gives a low yield of II. *Et p-nitrophenylazocarbonate*,

orange-red, m 76° 5', does not react with  $\text{NH}_4\text{OH}$ . *Me 2,4-dinitrophenylhydrazoncarboxylate*, brown yellow, m 134°, could not be nitrosated or dehydrogenated. *2,4-dinitrophenylhydrazoncarboxylate*, brown-yellow, m 168°, could not be nitrosated. *Me p-toluenophenylhydrazoncarboxylate* (IV) m 110°, stable toward  $\text{NH}_4\text{OH}$ . Its *nitroso deriv.*,  $p\text{-BrC}_6\text{H}_4\text{N}(\text{NO})\text{NHCO Me}$ , straw color, m 92° (decompn), unstable in air in boiling water it forms IV, with strong alkali it forms N and a low yield of  $p\text{-BrC}_6\text{H}_4\text{N}_2$  (V). *Me p-bromophenylhydrazoncarboxylate*, orange yellow m 75°, stable toward  $\text{NH}_4\text{OH}$ . It *p-bromophenylhydrazoncarboxylate* (VI), m 107°, stable toward  $\text{NH}_4\text{OH}$ . Its *nitroso deriv.*, yellow, m 101° (decompn) in boiling water or with  $\text{PhNH}_2$  it forms VI with strong alkali it forms N and a very low yield of V. *Me p-tolylhydrazoncarboxylate* m 112°, stable toward  $\text{NH}_4\text{OH}$ . Its *nitroso deriv.*, straw color, m 51°, not stable with hot aq.  $\text{NaOH}$  it forms N and a very small yield of  $p\text{-MeC}_6\text{H}_4\text{N}_2$ . *Me p-tolylcarboxylate* brilliant orange, m 29-30°, stable toward  $\text{NH}_4\text{OH}$ . It *p-tolylhydrazoncarboxylate*, m 55°, stable toward  $\text{NH}_4\text{OH}$ .  $p\text{-BrC}_6\text{H}_4\text{NHNHCONH}_2$  and  $p\text{-ONC}_6\text{H}_4\text{NHNHCONH}_2$  prep'd according to the description of Darapsky (C 21 2, 2089), m 225 and 220, resp (instead of 226 and 212° of D) each is stable toward  $\text{NH}_4\text{OH}$ . A light excess of  $\text{AmNO}$  and  $\text{HCl}$  added to a cold soln of  $p\text{-ONC}_6\text{H}_4\text{N}(\text{NO})\text{NHCHO}$  gives *formyl p-nitrophenylhydrazine*  $p\text{-ONC}_6\text{H}_4\text{N}(\text{NO})\text{NHCHO}$  (VII), straw color, m 109-110° (decompn) gives brown red solus in aq.  $\text{NaOH}$  which on boiling evolve N and form II. Suspended in EtO VII and  $\text{PhNH}_2$  form  $p\text{-ONC}_6\text{H}_4\text{NHNHCHO}$  m 185° (C Ber 32 1810(1899)). VII is an isomer of  $p\text{-ONC}_6\text{H}_4\text{N}(\text{NO})\text{NHCHO}$ , and was prep'd because it has some of the properties of the preceding nitroso ester. C C Davi

**Preparation of p-phenylenedihydrazine hydrochloride** H A J Schoutissen *J Am Chem Soc* 55, 1546 (1933). Reduction of t-tetrazotized  $p\text{-C}_6\text{H}_4\text{N}_2$  with  $\text{SnCl}_4$  in conc'd  $\text{HCl}$  gives *p-phenylenedihydrazine di-HCl*, decomps on warming, its structure followed from the prep'n of  $p\text{-C}_6\text{H}_4\text{N}_2$  and  $\text{C}_6\text{H}_5\text{Cl}$  and the *disphenylazide*, pale yellow which carbonylates on heating. C J West

**Breakdown of organic arsenic compounds** Bertil Englund *Swensk Kem Lids* 45 140 (1933).  $\text{PhCH AsO}_2\text{H}_2$  is est'd by titration with  $\text{NaOH}$  and bromo thymol blue. It is stable when dry but break down on re-crystn, giving  $\text{AsO}_2\text{H}_2$ . This reaction is hastened by  $\text{HCl}$ . It is monomol. In brominating  $\text{H O}_2\text{AsC}_6\text{H}_4\text{CO}_2\text{H}$ , the  $\text{HBr}$  formed catalyzes an analogous reaction giving  $\text{CBrCO}_2\text{H}$  and  $\text{AsO}_2\text{H}_2$ . In both m cases  $\text{As}_2\text{S}_3$  drops to  $\text{As}^{III}$ . A K Rose

**Nitrogenous arsenical derivatives** VI V Berlin kotti *Ann chim applicata* 23, 168 (1933). Correction. The third sentence in C 1 27, 333 should read: Each has been combined with  $p\text{-H O}_2\text{AsC}_6\text{H}_4\text{N}_2\text{N}(\text{OH})_2$ , 2,4 (III) and with  $p\text{-H O}_2\text{AsC}_6\text{H}_4\text{N}_2\text{N}(\text{OH})_2$ , 2,4 (IV). I J C

**The action of copper on aromatic acetomercuric derivatives** A Contardi and B Cecchi *Ann chim applicata* 23, 362 (1933). When  $(\text{PhC}_6\text{H}_4\text{CO})_2\text{Hg}$  is refluxed in benzene or toluene with Cu powder, and the product evap'd in *vacuo* almost pure  $\text{HgPh}_2$  is obtained. Zn powder may also be used. Similarly  $\text{EtNC}_6\text{H}_4\text{CH}_2\text{CO}_2\text{Hg}$  when treated above yield  $\text{PhNH}_2$ . A W Contardi

**Action of sulfur on organic compounds** XI Action of sulfur on bibenzyl Ludwik Szpil and Mucel Grdzysian *Roczniki Chem* 12 478 S(1931 in German) (1932) (C 21 24, 520). Baumann and Klett (*Ber* 24, 3312(1891)) and Szwed and Kowalski (*Chemik Polski* 16, 112(1914)) obtained by treating stilbene with S, a comp'd containing S, m 210°. This comp'd includes admixts of tetraphenylthiophene. After purification, the substance is S free, m 24°, approx mol wt corresponds to  $(\text{C}_6\text{H}_5)_4$ . Interaction of S and bibenzyl yields  $\text{H}_2\text{S}$ , tetraphenylthiophene and *seleffu*

*phenylbutane*, m 251.5-2.0°, formed by reduction of tetraphenylthiophene. J Wiertelak

**Preparation of some derivatives of triphenylgermanium by means of sodium triphenylgermanide** Charles A Kraus and Clarence S Sherman *J Am Chem Soc* 55, 4094 7(1933).  $\text{Ph}_3\text{GeNa}$  in liquid  $\text{NH}_3$  and  $\text{PrBr}$  (added by means of  $\text{NH}_3$ ) give *propyltriphenylgermanium*, m 86.6°, *Bu deriv.*, m 54.5-5.5°, *Am deriv.*, m 42.5°, *benzyl deriv.*, m 42.5-3.5°.  $\text{Ph}_3\text{GeNa}$  and  $\text{I tC}_6\text{H}_4\text{Bi}$  in  $\text{C}_3\text{H}_6$  give *triphenylgermanyltriethylgermanium*, m 59.5-90.5°. C J West

**Labilities or electronegativities of some unsaturated alkyl radicals as determined by hydrogen chloride scission of organolead compounds** Henry Calman, Edmund B Towne and H I Jones *J Am Chem Soc* 55, 1689-93(1933). In connection with relative stabilities, a study has been made of the rates of cleavage of unsym organolead compds by means of  $\text{HCl}$ . The relative order of labilities or so-called electronegativities of radicals is essentially that observed in the scission reactions of other organometallic compds by  $\text{HCl}$  [ $\alpha\text{-C}_6\text{H}_5\text{S}$  and  $\alpha\text{-C}_6\text{H}_7$ ].  $\text{Ph}$  [I] and  $\text{PhCl}$  [I] triphenylallyllead gives  $\text{Ph}_3\text{PbCl}$  and propene, indicating that the allyl group is more labile than the  $\text{Ph}$  group, likewise, the  $\beta$  vinyl group is cleaved before  $\text{Ph}$  however, the  $\text{Ph}$  radical is removed before the  $\beta$  butenyl radical. *Triphenylbutenyllead*, m 84.6° result in 96% yield from  $\text{ClI}$   $\text{ClI}$   $\text{HCl}$   $\text{MgBr}$  and  $\text{Ph}_3\text{PbCl}$   $\text{HCl}$  gives *di-phenylbutenyllead chloride* m 134° (decompn). *Triphenylbutenyllead*, b 78°, d<sub>4</sub> 1.5416, n<sub>D</sub> 1.5230,  $\text{HCl}$  gives ethyl 3-butenyllead dichloride. *Triphenylbutenyllead* m 104.9° *triphenyl naphthyllead*, m 131.  $\text{Ph}_3\text{PbCl}$   $\text{HCl}$  and  $\text{HCl}$  give *diphenylbutenyllead chloride*, m 157°. C J West

**Diastereoisomers of 2,5-diphenylsulfinylhydroquinone diacetate** Marion I Mackin and Roger Adams *J Am Chem Soc* 55, 1681 3(1933). Diphenylthiohydroquinone diacetate oxidized with  $\text{H}_2\text{O}$  in  $\text{AcOH}$  gives a mixt of  $\alpha$  and  $\beta$ , *diphenyl sulfinylhydroquinone 1,1 diacetate* m 207.5 and 143.5°, resp, these also results a mono sulfoxide  $\text{C}_6\text{H}_5\text{SO}_2$  m 112.5°. Oxidation of either disulfide gives  $\alpha$ , *diphenyl sulfinylhydroquinone diacetate* m 201.1° (decompn). Reduction of either  $\alpha$  or  $\beta$  sulfoxide gives the original thio comp'd. These 2 forms are the *meso* and *racemic* form and are the 1st example of such isomerism in a diarylsulfoxide. C J West

**Study of certain analogs of resolvable biphenyls** Marion I Mackin and Roger Adams *J Am Chem Soc* 55, 4088 8(1933). Dimethyl sulfox and conc'd  $\text{HNO}_3$  give the *3 di-NO deriv.* pale yellow, m 172°. All m p cor. reduction with Zn and  $\text{HCl}$  in  $\text{AcOH}$  gives the *NH deriv.*, m 217.5-5.5°. *Dinitrodimethylketone* m 171.2-2.2° (15.4°), *di-NH<sub>2</sub> deriv.*, yellow, m 16.4°. Reduction with  $\text{Zn-Hg}$  and dil  $\text{HCl}$  gives *3,3-diaminodimethylmethane* in 160 (60.5) (19.4°), *di-HCl salt* decomps 220-300°, 2,3,6,3,5  $\text{Me}_2(\text{O} \text{N}) \text{C COCl}$  and *mesitylene* with  $\text{AlCl}_3$  gives *3,3-dinitrodimethyl ketone* yellow, m 199-200°. Attempts to resolve the *NH* derivs through the capthor sulfone or bromo phosphorusulfonic salts resulted in failure. [a]<sub>D</sub> is given for each salt. This failure to demonstrate the presence of enantiomorphs in the 3 compds suggests a distortion of the tetrahedral structure of the S and the  $\text{CH}_3$  C atoms in these comp'd to a degree which permits free rotation of the methyl groups or perhaps a synchronous of the ring during rotation, or even both. C J West

**Thiols derived from  $\alpha$ ,  $m$  and  $p$  methoxytoluenes and benzoic acids** Madhavlal S Shah and Chinnubhai I Phatt and Duraid Kungu *J Chem Soc* 1933, 1775-81.

*Methoxytoluenes* sulfonic acid (I), oxidized with  $\text{PCl}_5$ ,  $\text{PbO}$  and the K salt of the acid heated with  $\text{PCl}_5$  gives *methoxytoluenes sulfonyl chloride* (II), an oil the *amide* m 145.4°. Reduction of I or II with Sn and  $\text{HCl}$  gives *3,2-HS(McO)C<sub>6</sub>H<sub>4</sub>Me*, b 235.6°, *Pb salt*, deep yellow, *Bz deriv.*, m 17°. *3-methylthiol-2-methoxytoluene*, b 254°, oxidation gives *3-methylsulfonyl-2*

*methoxybenzoic acid*, m. 166°. 2,4-O<sub>2</sub>N(HO<sub>2</sub>S)C<sub>6</sub>H<sub>3</sub>Me (Ba salt crystals with 2 mols. H<sub>2</sub>O; K salt) is reduced by (NH<sub>4</sub>)<sub>2</sub>S to the *o*-NH<sub>2</sub> deriv., from which the *diaz* compd., decomps. 104°, was prepd. and decompd. by H<sub>2</sub>O to 2,4-HO(HO<sub>2</sub>S)C<sub>6</sub>H<sub>3</sub>Me (Ba salt, crystals with 2 mols. H<sub>2</sub>O); Me<sub>2</sub>SO<sub>4</sub> gives 2-methoxytoluene-4-sulfonic acid, analyzed as the Na salt, with 1 mol. H<sub>2</sub>O, and the Ba salt, with 1.5 mols. H<sub>2</sub>O. The acid chloride is an oil and the amide m. 123°; reduction of the chloride gives 4-thiol-2-methoxytoluene, b. 238° (Pb salt, yellow); 4-methylthiol deriv., b. 255-6°; 4-methylsulfonyl-2-methoxybenzoic acid, m. 156°. 4-Sulfo-2-methoxybenzoic acid, deliquescent, m. 152° (Pb salt); 4-chlorosulfonyl deriv. (III), m. 149.5°; 4-amidosulfonyl deriv., m. 201°. Reduction of III gives 4-thiol-2-methoxybenzoic acid, m. 95°; 4-methylthiol deriv., m. 112°. 5,2-HS(MeO)C<sub>6</sub>H<sub>3</sub>Me gives a Bz deriv., m. 80°; 5-methylthiol-2-methoxytoluene, b. 259°; oxidation gives 5-methylsulfonyl-2-methoxybenzoic acid, m. 190°. 5-Thiol-2-methoxybenzoic acid, m. 205°; 5-methylthiol deriv., m. 70°. 2-Methoxytoluene-6-sulfonic acid (K salt, crystals with 1 mol. H<sub>2</sub>O) gives a chloride, oily, and an amide, m. 104°. 6-Thiol-2-methoxytoluene, b. 238° (Bz deriv., m. 62°; disulfide, m. 80°); 6-methylthiol deriv., b. 256°. 2-Thiol-3-methoxytoluene, b. 256°; disulfide, m. 148°. 2-Methylthiol-3-methoxytoluene, b. 269°; 2-methylsulfonyl-3-methoxybenzoic acid, m. 212°. 5-Thiol-3-methoxytoluene, b. 251°; 5-methylthiol deriv., b. 263°; 5-methylsulfonyl-3-methoxybenzoic acid, m. 195°. 5-Thiol-3-methoxybenzoic acid, m. 162°; 5-methylthiol deriv., m. 155°; reduction of 4-chlorosulfonyl-3-methoxybenzoic acid gives 3-methoxybenzoic acid *o*-disulfide, m. 228°. 2,5-HS(MeO)C<sub>6</sub>H<sub>3</sub>Me forms a Bz deriv., m. 84°; 6-methylthiol-3-methoxytoluene, b. 272°; oxidation gives 6-methylsulfonyl-3-methoxybenzoic acid, m. 180°. 2-Thiol-4-methoxytoluene, b. 263°; 2-methylthiol deriv., b. 260°; 2-methylsulfonyl-4-methoxybenzoic acid, m. 180°; 3-methylsulfonyl isomer, m. 215°. 3-Sulfo-4-methoxybenzoic acid, m. 250° (K salt, with 2 mols. H<sub>2</sub>O; Ba salt, with 2 mols. H<sub>2</sub>O); 3-chlorosulfonyl-4-methoxybenzoic chloride, m. 70°; 3-amidosulfonyl-4-methoxybenzamide, m. 262°; 3-chlorosulfonyl-4-methoxybenzoic acid, m. 178°; 3-thiol-4-methoxybenzoic acid, amorphous, m. 317° (decomps.); 3-methylthiol deriv., m. 205° C. J. West

**Chloro derivatives of benzylphenols. II. Some monochloro, dichloro and trichloro derivatives of *o*- and *p*-benzylphenols** R. C. Huston, R. L. Guile, P. S. Chen, W. N. Headley, G. W. Warren, L. S. Bau and R. O. Mate. *J. Am. Chem. Soc.* 55, 4639 (1933), cf. C. A. 25, 3635. The following chlorodiphenylmethanes were prepd. by the AlCl<sub>3</sub> or Claisen method: 2-hydroxy-2', b. 146.51°, 16.2% yield; -3-, m. 40.5 1.5°, 27%; -3', b. 192.4°, 7.78%; -4', m. 60.1°, 25%; 4-hydroxy-2', m. 68.9°, 11.7%; -3-, b. 145.8°, 40%; -3', b. 200-2°, 15.8%; -4', m. 87.75°, 46%; 2-hydroxy-5,4'-di-, m. 44.5 5.5°, 15%; -3,5,2'-tri-, m. 59.5 60.5°, -3,5,3'-tri-, m. 59.4 60°, 4.56%; -3,5,4'-tri-, m. 69.5 70.5°; 4-hydroxy-3,5,2'-tri-, m. 86.5 7.5°, 16.8%; -3,5,3'-tri-, m. 79.80°, 11.5%; -3,5,4'-tri-, m. 61.5 2.5°, 35%. *Ethers*: 2-chlorobenzyl Ph, b. 110.5°; 3-Cl isomer, m. 66.1°, 10.9°; 4-Cl isomer, m. 85.5 6.5°, 5.8%; 4-chlorobenzyl 4-chlorophenyl, m. 80.1°, 3%; 2-chlorobenzyl 2,4-dichlorophenyl, m. 61-2°; 3-Cl isomer, m. 12.25°, 1.46%; 4-Cl isomer, m. 64.5 5.5°; 2-chlorophenyl benzyl, b. 138.40°, 7.5%; 4-Cl isomer, m. 70.1°; 4-chloro-2-benzylphenyl benzyl, m. 53.4°, 59%. **Benzoyl esters of chlorodiphenylmethanes**: 2-hydroxy-2', b. 173.6°; -3-, m. 69.71°; -3', m. 67.7.4°; -5-, m. 51.5°; 4-hydroxy-2', m. 64.5 5.5°; -3-, m. 71.3°; -5-, m. 57.5°; -4', m. 115.6°; 2-hydroxy-5,4'-di-, m. 84.5 5.5°; -3,5,2'-tri-, m. 81.2°; -3,5,3'-tri-, m. 63.5 4.0°; 4-hydroxy-3,5,2'-tri-, m. 86.7°; -3,5,3'-tri-, m. 130.30.4°; -3,5,4'-tri-, m. 116.7°. **Benzenesulfonyl esters**: 2-hydroxy-2', m. 62.4°; -5-, m. 68.9°; 4-hydroxy-3, m. 65.8°; 2-hydroxy-3,5,3'-tri-, m. 114.5 5°. ***p*-Toluenesulfonyl esters**: 2-hydroxy-3-, m. 81.5 3.5°; -5-, m. 75.7.5°; 4-hydroxy-3-, m. 51.3°; 2-hydroxy-3,5,3'-tri-, m. 125.4.6°; 4-hydroxy-3,5,3'-tri-, m. 104.5-

5°. No ethers were formed in the AlCl<sub>3</sub> condensation where Cl was present in the nucleus of the PhCH<sub>2</sub>Cl. In the Claisen reaction the presence of Cl in the nucleus of the PhCH<sub>2</sub>Cl exerted a retarding influence on the yield of benzylated phenol and its corresponding ether, the greatest retarding effect being exhibited when the Cl was in the *m*-position, the next when in the *o*-position. The yields of the benzylated phenols by the Claisen reaction in case of *m*-substituted benzyl chlorides was increased by adding the corresponding benzyl ether to the reaction mixt. C. J. West

**Oxyacanthin and berbamine. III.** F. v. Bruchhausen, H. Oberembit and A. Feldhaus. *Ann.* 507, 144-59 (1933); cf. C. A. 25, 2983. 2,5'-1-hydroxy-3,4'-diethyl-5,6,2'-trimethoxy-1,1'-diphenyl ether, previously obtained from oxyacanthin (I), is reduced by Zn and AcOH-HCl to the 2,5'-di-Me deriv. (II), m. 86.5°. This was synthesized as follows: 3,6-Me(MeO)C<sub>6</sub>H<sub>3</sub>OH and Ac<sub>2</sub>O give the Ac deriv., converted by AlCl<sub>3</sub> in PhNO<sub>2</sub> to acetosorresol (2-methyl-4-hydroxy-5-methoxyacetophenone), m. 124° (semicarbazone, m. 224°; oxime, m. 174°); reduction gives 80% of 1-methyl-3-hydroxy-4-methoxy-6-ethylbenzene (III), m. 57.5° (Bz deriv., m. 71°); the 2-Hr deriv. (IV) m. 51.5° (90% yield). IV was also prepd. as follows: 2-Bromovanillin on reduction gives 50% of 1-methyl-2-bromo-3-hydroxy-4-methoxybenzene, m. 98°, AcCl and AlCl<sub>3</sub> give 50% of 2-methyl-3-bromo-4-hydroxy-5-methoxyacetophenone, m. 82° (semicarbazone, m. 214°), reduced by Zn and HCl to IV. IV and CH<sub>3</sub>N<sub>2</sub> in Et<sub>2</sub>O give 1-methoxy-2-bromo-3,4-dimethoxy-6-ethylbenzene, b. 80°. Condensation of III and IV in MeOK with Naturkupper C and Cu(OAc)<sub>2</sub> gives II. Berbamine (V) yields a Me ether (VI), m. 182°, which analyzes for C<sub>20</sub>H<sub>16</sub>O<sub>4</sub>N<sub>2</sub>; V is then an isomer of I. The Hofmann degradation of VI gives a mixt. of 2 methine bases, A (cf. Santos, C. A. 24, 1647), and B, m. 146.7°. The base A and O<sub>2</sub> give the same products as I. V and tetrandine are optical isomers, while I is a structural isomer of these 2. C. J. West

**A new class of "free" radicals.** A. Schonberg and E. Rupp. *Naturwissenschaften* 21, 561 (1933). On dissolving PhS<sub>2</sub> or (α-C<sub>10</sub>H<sub>7</sub>CS)<sub>2</sub>S<sub>2</sub> in indifferent solvents the substances partially decomp., forming free radicals with univalent S atoms: phenylthiyl (PhS) and thionaphthylthiyl (C<sub>10</sub>H<sub>7</sub>C(S)S). The solns. do not conform to Beer's law; they are thermochromic. Solns. of diphenylene disulfide follow this law; with them possible decompn. does not change the no. of mols. The free radicals are named "thiyls"; they bind heavy metals at room temps., like radicals with trivalent C and aliphatic diazo compds. B. J. C. van der Hoeven

**Thiophenol chemistry. Condensation reaction between thiophenols and condensed aldehyde-ammonias.** Gregg Dougherty and Wendell H. Taylor. *J. Am. Chem. Soc.* 55, 4588 (1933); cf. C. A. 27, 1873. Hexamethylenetetramine (I) is decompd. by PhSH when boiled in 1,4-dioxane soln.; 2 atoms N per mol. of I are eliminated as NH<sub>3</sub>, the other product being N(CH<sub>2</sub>-SPh)<sub>2</sub>; other thiophenols and mercaptans cause analogous decompns., the following mercaptomethylamines being formed: tri-*p*-bromophenyl, m. 135°; tri-*p*-nitrophenyl, yellow, m. 146°; tri-*p*-tolyl, m. 52°; tribenzyl, m. 40°. Hydrobenzamide, hydrofurfuramide and other hydramides are partially decompd. by thiophenols, yielding the typical product RCH=NCH(SR')R, as well as NH<sub>3</sub>. benzalphenylmercaptobenzylamine, m. 79.5°; benzalbenzyl deriv., m. 67°; benzal-*p*-tolyl deriv., m. 74°; 3-nitrobenzalphenylmercapto-3'-nitrobenzylamine, pale yellow, m. 123°; methylbenzalphenylmercaptotolylamine, m. 71°; furfuralphenylmercaptofurfurylamine, m. 49°. On warming with alc. Ph(OAc)<sub>2</sub> a mercaptide ppt. forms. On distn. these compds. decomp. N(CH<sub>2</sub>SPh)<sub>2</sub> gives PhS<sub>2</sub>. Dil. alk. KMnO<sub>4</sub> does not oxidize PhCH=NCH(SPh)<sub>2</sub>Ph, while 30% H<sub>2</sub>O<sub>2</sub> gives complete decompn., forming H<sub>2</sub>OH; with H<sub>2</sub> the chief product is PhS<sub>2</sub>. C. J. W.

**Alkyl derivatives of halogen phenols and their bactericidal action. II. Bromophenols.** Emil Klarman,

Louis W. Cate, Vladimir A. Shternov, and Philip H. Cox, Jr. *J. Am. Chem. Soc.* 55, 1057 (1933), cf. C 1 27, 3156. The following 2-alkyl derivs. of 4-bromo-phenol are reported: Me, b<sub>1</sub> 118.2°, m b<sub>2</sub> 5°, f<sub>1</sub> 110°, p<sub>1</sub> 113°, m 12°, Bu, b 125.7°, m 13.5°, 1m, b<sub>1</sub> 115.5°, m 36°, sec 1m, b<sub>1</sub> 134.8°, hexyl, b<sub>1</sub> 150.2°, m 33.6°, cyclohexyl, b 100°, m 3.8°, 1-tert-amyl, 2-bromophenol, b<sub>1</sub> 122°, 4-propyl, 2-dimethyl deriv, m 91.3°, 4-hexyl deriv, b<sub>1</sub> 145°, 2-bromo-2-hydroxypropylphenone m 133°, butyl phenone, b<sub>1</sub> 131.2°, m 55.6°, chlorophenol b<sub>1</sub> 134.6°, caprophenone, m 60°, 4-Bromophenyl acetal, b 100°, propionate, b 114°, butyrate, b 112°, d rate, b<sub>1</sub> 134.8°, caproate, b 133.40°. Four pathogenic microorganisms were used in the bacterial expt. *Escherichia typhi*, *Staphylococcus pyogenes aureus*, *Mycobacterium tuberculosis* (Horn) and *Mycobacterium africanum* when treated with the acid or these substituted bromophenol derivs. were found to be strongly germicidal and to compare favorably in this respect with the Cl deriv. studied previously. A in the latter case the constitution of the mol. and the wt. of the substituents not only influence the intensity of the germicidal action but also the point at which the quaternary effect becomes apparent, i.e., where the germicidal action of a given compd. with respect to the Gram neg. *Escherichia typhi* decline or practically disappear while at the same time reaching very considerable height with regard to pathogenic cocci and fat bacteria and pathogenic fungi. C. J. West.

**Action of nitrous acid on pyrocatechol-4-sulfonic acid** J. Frank and J. Zikl. *Colloidi in Czechoslov. Chem. Communication* 5, No. 6, 233 (1933) (in French) cf. C 1 26, 101. The starting point of the work was the Na or K salt of pyrocatechol-4-sulfonic acid (I), prepd. by heating pyrocatechol with concd. H<sub>2</sub>SO<sub>4</sub>, neutralizing the mixt. with BaCO<sub>3</sub> and treating the recrystd. Ba salt of I with the calcd. amt. of Na or K nitrate. It was H<sub>2</sub>O (from dil. H<sub>2</sub>SO<sub>4</sub> or HCl) + NaNO<sub>2</sub> reacted with the Na salt of I to give the Na deriv. of the diNO deriv. of I, the acid permitted the mono NO deriv. to be obtained also. Despite repeated attempt, the triNO deriv. could not be prepd. The free diNO deriv. was obtained by the treatment of HCl on the Na or K deriv. The following derivs. of the diNO compd. are described: Na and K derivs., yellow brown needle-like acid, golden yellow needle-like explosive. Ba deriv., small, golden yellow needles, very explosive. Sr deriv., similar to Ba deriv. Ca deriv., golden yellow lamellae. Ag deriv., very explosive needles. The above derivs. are mostly only slightly sol. in warm H<sub>2</sub>O and org. solvs. Reduction of the free diNO compd. (with Sn and HCl) gave the HCl salt of the corresponding diamine (white needles, very sol. in H<sub>2</sub>O). Oxidation of the diamine reducing diamine (by air or FeCl<sub>3</sub>) yielded a light green ppt. of the corresponding diamine, nearly insol. in H<sub>2</sub>O and org. solvent. The picric acid golden yellow needle, unstable in air and the Ac deriv. (the white crystals, very slightly sol. in H<sub>2</sub>O and org. solvent) of the diamine acid were also prepd. Edward B. Smiger.

**Condensation of dinitrochlorobenzene with p-amino phenol 3,5-disulfonic acid** I. M. Kargin, A. S. Antonov, and A. Z. Lyubitsky. *Indian Travschinaya Tr. m.* 3, 133 (1933). A yield of 80% 2,4 (ON) C<sub>6</sub>H<sub>3</sub>NH<sub>2</sub>H (SO<sub>3</sub>Na)<sub>2</sub> (O<sub>2</sub>S)<sub>2</sub> (I) was obtained by refluxing 10 hr. in a salt bath (mixt. of 10% 1,4,5,6 C<sub>6</sub>H<sub>3</sub>(NH<sub>2</sub>)(OH)(SO<sub>3</sub>Na)<sub>2</sub> and 6% CH<sub>3</sub>CO<sub>2</sub>Na) 2,4 (ON) C<sub>6</sub>H<sub>3</sub>NH<sub>2</sub> and 60 cc. H<sub>2</sub>O and then filtering out with NaCl. By working with the 39% of I results. I give fugitive yellow dyeing on wool from an acid bath. C. B.

**Structure of dimeric modifications of propenylphenol ethers** I. J. Harriett and I. Seck. *Ind.* 507, 197 (1933) cf. C 1 27, 3922, 1 with a proof of the structure of the intermediate compd. (I) in the synthesis of dioxugenol I and in its reaction with AcOAc in AcOH, 1-tert-butyl, C<sub>6</sub>H<sub>5</sub>O, 11.33, 10 mg. formed. Similarly, AgNO<sub>3</sub> in EtOH gives a NO compd., C<sub>6</sub>H<sub>5</sub>(NO)<sub>2</sub>N, m 125°. A stannic dibromide and Cu bronze or Zn dust in C<sub>6</sub>H<sub>5</sub> give the compd. (II), m 123°. II and MeOH-KOH give the

unsatd. compd., C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>, m 101°, while Zn dust in EtOH gives diasaronic, m 102°.

C. J. West

**Constitution of the reaction product of benzo- and naphthoquinone with compounds which contain two negative groups neighboring to a methylene group** W. Kesting. *J. prakt. Chem.* 338, 215 (1933), cf. C 1 23, 357. CH(CN) (I) and C<sub>6</sub>H<sub>4</sub>O (II) in EtOH, treated with NH<sub>3</sub> for a short time, give a brick red ppt., II NH<sub>3</sub>, which darkens in the air. I (1 mol.) and 2 mol. II give a bluish black ppt., I II · 2NH<sub>3</sub>. Formulas are proposed for these compds. C. J. West.

**Reactions of aldoxime derivatives with bases** I. Charles R. Hann and C. I. Sullivan. *J. Am. Chem. Soc.* 55, 4611 (1933). Certain acetyl β-aldoximes react with NaOH to form partly nitrile and partly β-oxime. The following yields were obtained from acetyl β-benzaloximes and acq. alkali at 0°, 4 MeO 2, 6, 3 NO 3, 10 at 30°, 1 MeO 3, 30, 3 NO 2, 2. In EtOH at 0° 1 MeO 3, 30, 4 Cl 3, 60, 3, 3 methyl endoxy 22, 30, at 30° 1 MeO 6, 31, 4 Cl 6, 30, 3, 4 methylendoxy 64, 2. NaCO at 0° or 30° gave 70-90% of the corresponding nitrile. C. J. West.

**Cleavage of the aldehyde group as formic acid from aromatic aldehydes** I. Polychlorobenzaldehydes. Gunther Lock. *Ber.* 66B, 152 (1933). Certain aromatic aldehydes split off the CHO group quantitatively as HCOH with alkali. The cleavage seems to depend on the position and probably on the nature of the substituent. BrH and its m Cl, m Br, o and p Cl, the s NO and HO, p Me, p Et, p Ph and 2,5 Me, and 2,3, 2,4- and 3,4 Cl<sub>2</sub> derivs. have been studied. All of these, excepting the o and p HO C<sub>6</sub>H<sub>4</sub>CHO, react normally being disproportionated into acid and alcohol 2 C<sub>6</sub>H<sub>4</sub>CHO however is broken down quantitatively into o C<sub>6</sub>H<sub>4</sub>Cl and HCO<sub>2</sub>H, a new also 2,3,6 and 3,4,6 C<sub>6</sub>H<sub>3</sub>Cl<sub>3</sub>CHO and C<sub>6</sub>H<sub>3</sub>Cl<sub>3</sub>CHO. Either KOH or NaOH can be used, but not NaCO<sub>3</sub>, NH<sub>3</sub>, or PhNH<sub>2</sub>. NaCO<sub>3</sub> on the water bath does not attack 2,3,6 C<sub>6</sub>H<sub>3</sub>Cl<sub>3</sub>CHO and the NH convert it into an untypical glycol containing much of all hydro, CHCl or HCOH. Derivs. of m HO C<sub>6</sub>H<sub>4</sub>CHO and m MeO C<sub>6</sub>H<sub>4</sub>CHO in which the o position to the CHO group are occupied by Cl or Br (2,6, 3 Cl (HO)C<sub>6</sub>H<sub>3</sub>CHO) likewise split off the CHO group, while the 1,6 Br and 2-chloro-3-bromo derivs. are normally disproportionated. C. A. R.

**Synthesis of hydroxyephedrine** J. Amigos Anoro. *Rev. acad. cienc. Madrid* 3, 216 (1933). The properties and properties of hydroxyephedrine and related compds. are reviewed and over 100 references given. Hydroxyephedrine can be prepd. from hydroxyphenyl alkyl ketones. With the aid of AlCl<sub>3</sub> A prepd. from PhOH and EtCOCl or MeCH<sub>2</sub>BrCOCl, o and p hydroxypropionophenone, and the new compd., o and p hydroxyisobutyrophenone, HO C<sub>6</sub>H<sub>4</sub>COCH<sub>2</sub>CH<sub>2</sub>Me, of which latter the o compd. was volatile with steam and very irritant to the skin and mucosa, m 32°, and formed a 2,4-dinitrophenylhydrazon, orange, m 144°. The compd. not volatile with steam, m 81° (decolorate in 57%), 2,4-dinitrophenylhydrazon, dark red, m 117° (decompos.). The yields were 25-50%. The prepn. of 3,4-dihydroxypropionophenone (from pyrocatechol) and several of its derivs. is described, also o hydroxyphenyl a-methylaminoethyl ketone, HO C<sub>6</sub>H<sub>4</sub>COCH<sub>2</sub>(NHMe)<sub>2</sub>. Me. I. J. Gilson.

**The mechanism of the Perkin Oghaloro synthesis** M. Babin. *Rend. accad. sci. (Napoli)* [1] 2, 20 (1933). B gave credit to Oghaloro for the modification of the Perkin synthesis usually credited to Fittig. Intermediate compds. recently isolated in study of the reaction are iddin compd. between the salt and the acid or anhydride. The bond seems to be between the car-

III with EtOH-KOH gives the K salt, crystals with 1.5 mols. H<sub>2</sub>O, of  $\beta$ , $\beta$ -dimethoxy- $\gamma$ -hydroxybutyric acid, m. 129° (decompn.); after 1 crvstn. from aq. MeOH about 50% was converted to III. I and Me<sub>2</sub>SO<sub>4</sub> in 20% NaOH gives  $\alpha$ , $\gamma$ -diphenyl- $\alpha$ , $\beta$ -dihydroxy- $\gamma$ -methoxybutyric acid, m. 201°, and a small amt. of a di-MeO acid, m. 148 9°.

C. J. West

**General method for the preparation of di- and tri-arylacetonitriles.** J. Hoch. *Compt. rend.* 197, 770 2 (1933); cf. C. A. 27, 3028.—The reaction of PhCHBrCN with C<sub>6</sub>H<sub>6</sub>, PhMe, *p*-xylene, PhOMe and C<sub>10</sub>H<sub>18</sub>; *p*-MeC<sub>6</sub>H<sub>4</sub>CHBrCN with PhMe and *p*-xylene; 1-C<sub>10</sub>H<sub>7</sub>CHBrCN with C<sub>6</sub>H<sub>6</sub> and 2-C<sub>10</sub>H<sub>7</sub>CHBrCN with *p*-xylene in the presence of AlCl<sub>3</sub> gave the following corresponding compds. (% yields in parentheses): Ph<sub>2</sub>CHCN, m. 76° (75%);  $\alpha$ -phenyl- $\alpha$ -(*p*-tolyl)acetoneitrile, m. 62° (59%);  $\alpha$ -phenyl- $\alpha$ -(2,5-dimethylphenyl)acetoneitrile, m. 52° (55%);  $\alpha$ -phenyl- $\alpha$ -(*p*-amyl)acetoneitrile, m. 127° (35%);  $\alpha$ -phenyl- $\alpha$ -(1-naphthyl)acetoneitrile, m. 98° (67%); di-*p*-tolylacetoneitrile, b<sub>18</sub> 212° (62%);  $\alpha$ -*p*-tolyl- $\alpha$ -(2,5-dimethylphenyl)acetoneitrile, b<sub>18</sub> 212° (62%);  $\alpha$ -phenyl- $\alpha$ -(1-naphthyl)acetoneitrile, m. 90° (35%); and  $\alpha$ -2,5-dimethylphenyl- $\alpha$ -(2-naphthyl)acetoneitrile, m. 106° (40%). PhCBrCN with C<sub>6</sub>H<sub>6</sub> and PhMe gave, resp., Ph<sub>2</sub>CCN, m. 128° (15% yield), and  $\alpha$ -phenyl- $\alpha$ , $\alpha$ -di-*p*-tolylacetoneitrile, m. 134° (33% yield). Ph<sub>2</sub>CBrCN likewise treated with C<sub>6</sub>H<sub>6</sub> and PhMe gave, resp., Ph<sub>2</sub>CCN, m. 128° (60% yield), and  $\alpha$ , $\alpha$ -diphenyl- $\alpha$ -(*p*-tolyl)acetoneitrile, m. 111° (62% yield).  $\alpha$ -Phenyl- $\alpha$ -(*p*-tolyl)- $\alpha$ -bromoacetoneitrile condensed with *p*-xylene gave  $\alpha$ -phenyl- $\alpha$ -(*p*-tolyl)- $\alpha$ -(2,5-dimethylphenyl)acetoneitrile, m. 148° (45% yield).  $\alpha$ -Phenyl- $\alpha$ -(2,5-dimethylphenyl)- $\alpha$ -bromoacetoneitrile with C<sub>6</sub>H<sub>5</sub>OMe gave  $\alpha$ -phenyl- $\alpha$ -(2,5-dimethylphenyl)- $\alpha$ -(*p*-amyl)acetoneitrile, m. 164° (45% yield). J. W.

**Course of the reaction in amalgam hydrogenations;  $\beta$ -phenylsorbic acid.** Richard Kuhn and Max Hoffer. *Ber.* 66B, 1263 73 (1933). The sym. diphenylpolyenes and carotenoid carboxylic acids which with Na and Al amalgams give  $\omega$ , $\omega'$ -dihydro compds. have pronouncedly "neg." substituents (Ph, CO<sub>2</sub>H) only at the ends of the polyene chains. Aliphatic polyenemonocarboxylic acids also undergo predominantly  $\omega$ , $\omega'$ -addn. What will happen with unsymmetrically situated "neg." substituents cannot be foretold, however. Burton and Ingold predicted that butadienes with 2 "neg." substituents in the 1,2-position would add H at the 1,2-position (C. A. 24, 39), but K. and Deutsch (C. A. 26, 4012) found that PhCH=C(CH<sub>3</sub>:CH<sub>2</sub>)CO<sub>2</sub>H adds H almost exclusively at the 1,4-position to form PhCH<sub>2</sub>C(CH<sub>3</sub>:CHMe):CO<sub>2</sub>H instead of PhCH<sub>2</sub>CH(CH<sub>3</sub>:CH<sub>2</sub>)CO<sub>2</sub>H. As, however, the latter acid is unknown and may be even more unstable than PhCH<sub>2</sub>CHCH<sub>2</sub>CO<sub>2</sub>H, which readily changes into MeC<sub>2</sub>H:CHCO<sub>2</sub>H,  $\beta$ -phenylsorbic acid, MeCH:CHCH:CH:CO<sub>2</sub>H (I), was carefully reduced with Na-Hg. Oxidative degradation of the product with KMnO<sub>4</sub> gave 27.5% HO<sub>2</sub>CCH<sub>2</sub>CHPhCO<sub>2</sub>H, 68.2% Br<sub>2</sub>OH, 29.0% AcOH and 70.0% EtCO<sub>2</sub>H. I therefore undergoes 70% 1,4- and only 30% 1,2-addn.; the 2 dihydro acids are so stable that a secondary formation of the  $\Delta^2$ - from the  $\Delta^1$  acid is improbable. K. and H. believe the 1st stage in the reduction is the addn. of 1 Na or H atom on a C atom adjacent to the "neg." substituents and that the relative extents of 1,2- and 1,4 addn. depend on the stability relationships of the tautomeric monohydro compds. In comparative expts. on sorbic acid with very carefully purified Na-Hg and ordinary Na-Hg prepd. in an Fe dish and handled with metal knives, no appreciable difference in the extent of 1,2-addn. was noted (40.2-3.0% with ordinary, 44.2-6.5% with purified Na-Hg). I was synthesized by condensing MeC<sub>2</sub>H:CHCO<sub>2</sub>Ph with BrCH<sub>2</sub>CO<sub>2</sub>Me in the presence of Zn to the Me ester (yield, 70%) of  $\beta$ -phenyl- $\beta$ -hydroxy-sorbic acid (II); this ester on listn. *in vacuo* with a few drops POCl<sub>3</sub> gave 40% of the Me ester of I. The free II smoothly splits off CO<sub>2</sub> and H<sub>2</sub>O above its m. p., and if the decompn. is carefully carried out *in vacuo* there is obtained 2-phenyl-1,3-pentadiene (III), which readily polymerizes to a clear viscous rubber. With Br in CHCl<sub>3</sub>, II simultaneously loses HBr and H<sub>2</sub>O,

forming a lactone C<sub>13</sub>H<sub>11</sub>O<sub>2</sub>Br (presumably IV) which is reduced by Zn dust and AcOH to the Br-free lactone C<sub>13</sub>H<sub>13</sub>O<sub>2</sub> (V). With alc. HCl, about half of V is converted into the Me ester of I and 1/4 of it rearranges into an isomer (presumably VI). The absorption spectra of the 2 lactones indicate clearly that the Ph and CO<sub>2</sub>O groups are in conjugation in VI but not in V. V is most simply obtained by treating II or its Me ester with AcOH-HCl. The Me ester, m. 58°, of II gives with Br in CS<sub>2</sub> a mono-Br deriv. m. 178-80° (m. ps. cor., Berl black). II m. 121-2°. IV, m. 110-0.3°, is sol. in dil. NaOH only after boiling some time. III, b<sub>18</sub> 85 6°, d<sub>4</sub><sup>20</sup> 0.915, n<sub>D</sub><sup>20</sup> 1.5500. Me ester of I, b<sub>18</sub> 154-6°, d<sub>4</sub><sup>20</sup> 1.049, n<sub>D</sub><sup>20</sup> 1.5040, I m. 133 4°. V m. 99-100°. VI, m. 63°, hardly decolorizes Br in CS<sub>2</sub> but reduces KMnO<sub>4</sub> in cold Na<sub>2</sub>CO<sub>3</sub>.

C. A. R.

**Addition reactions of unsaturated  $\alpha$ -ketonic acids. III.** Marie Reimer and Helen H. Kamerling. *J. Am. Chem. Soc.* 55, 4643 8 (1933); cf. C. A. 22, 3885. *m*-MeOC<sub>6</sub>H<sub>4</sub>CHO and AcCO<sub>2</sub>H give 90% of the K salt of *m*-methoxybenzalpyruvic acid (I), yellow, m. 116 7°; H<sub>2</sub>O<sub>2</sub> gives 96% of *m*-MeOC<sub>6</sub>H<sub>4</sub>CH:CHCO<sub>2</sub>H; Me ester, m. 57°; if the MeOH-HCl soln. is heated to boiling there results the di-Me acetal of the Me ester, m. 72°; this is not formed from the ester itself; Et ester, bright yellow oil. I and Br<sub>2</sub> in CHCl<sub>3</sub> give the dibromide, which could not be purified; shaken with cold H<sub>2</sub>O, it gives the  $\beta$ -Br deriv. (II), m. 166 7°; Me ester, m. 95°; oxidation gives  $\alpha$ -bromo-*m*-methoxycinnamic acid, m. 122°, in 81% yield; Me ester, pale yellow oil; 1 mol. Br<sub>2</sub> gives  $\alpha$ -bromo-*ti*-bromo-3-methoxycinnamic acid, cream, m. 167 9°; Me ester, m. 79°. I and excess Br give  $\alpha$ -bromo-*ti*-bromo-3-methoxystyrene, pale yellow, m. 90°. II and Br in CHCl<sub>3</sub> give  $\beta$ -bromo-6-bromo-3-methoxybenzalpyruvic acid, m. 137 9°, readily decomp. on standing in soln.; Me ester, m. 143°.

C. J. West

**Synthesis of cinnamic acids.** Julius v. Braun and Johannes Nelles. *Ber.* 66B, 1464-70 (1933).—*iso*-AmCH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> is instantly brominated in ether to the  $\alpha$  Br acid, decomp. 132°, which when heated several hrs. with 10-12 mols. concd. KOH gives *iso*amyltartronic acid, m. 134 6° (decompn.), and this is readily decarboxylated *in vacuo* to  $\alpha$ -hydroxyisocanthic acid, b<sub>18</sub> 150°, m. 60°. Bromohexahydrobenzylmalonic acid, m. 146° (decompn.), similarly obtained, yields hexahydrobenzyltartronic acid, decomp. 138 40°, decarboxylated to the oily acid C<sub>6</sub>H<sub>5</sub>CO<sub>2</sub>H, b<sub>18</sub> 170°, which on slow heating from 120° to 170° gives, in poor yield, cyclohexylacetaldehyde. A whole series of substituted cinnamic acids can be obtained, however, from substituted  $\alpha$ -bromomalononic acids. The latter split off both HBr and CO<sub>2</sub> on mere heating; they can also be treated with alkali first and then decarboxylated, or, as will probably generally be the more practicable way, they can be decarboxylated first and then treated with alkali. The practical significance of this method of synthesizing cinnamic acids is that the starting materials, RCH<sub>2</sub>Cl or RCH<sub>2</sub>Br (R = aryl), are often easily prepd. by halogenating aromatically bound Me groups or by introducing the CH<sub>2</sub>Cl group into aromatic compds. by means of HCHO and HCl. *p*-ClC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>Cl and 1.2 mols. CH<sub>3</sub>(CO<sub>2</sub>Et)<sub>2</sub> give, together with di-Et bis(*p*-chlorobenzyl)-malonate, b<sub>18</sub> 220 30°, m. 99°, 50% di-Et *p*-chlorobenzylmalonate, b<sub>18</sub> 190 2°, rapidly and completely hydrolyzed by alkali to the free acid, m. 149-51° (decompn.), whose thick yellow oily  $\alpha$ -Br deriv. on decarboxylation at 160 70° in the vacuum of a water pump yields  $\alpha$ -bromo-*p*-chlorohydrocinnamic acid, b<sub>18</sub> 190°, m. 99°, this acid heated 2 hrs. with 30% NaOH gives *p*-ClC<sub>6</sub>H<sub>4</sub>CH:CHCO<sub>2</sub>H, m. 241°, which when heated several hrs. at 100° with AcOH-HBr, ddd. with water, filtered and warmed a short time with aq. Na<sub>2</sub>CO<sub>3</sub> yields *p*-chlorostyrene, b<sub>18</sub> 33 5°, d<sub>4</sub><sup>20</sup> 1.1554, n<sub>D</sub><sup>20</sup> 1.5742, polymerizes quite rapidly. Di-Et bis(*p*-bromobenzyl)malonate,

b<sub>0</sub>, 250-60°, m 104°, *Di-Et p-bromobenzylmalonate* (yield, 70%), b<sub>0</sub>, 193-8°, free acid, m 151-3° (decomps), forms an  $\alpha$ -B<sub>1</sub> deriv, m 88-102°, converted at 160° in the vacuum of a water pump in great part into *p*-BrC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>CHCO<sub>2</sub>H (I) (the elimination of HBr is effected quantitatively by treating the decarboxylation product with concd NaOH) which, through the chloride, b<sub>0</sub>, 175-80°, anilide, m 143°, and mucl chloride (Sonn and Muller method, C A 14, 1985), gives 60% *p*-bromo-*Ann*maldehyde, m 81° (semicarbazone, m 240), *phenylhydrazones*, yellow, m 145°  $\beta$ , *p*-*Dibromohydrocinnamic acid*, from I with HBr-AcOH at 100° in a sealed tube, m 182°, converted by short heating with Na<sub>2</sub>CO<sub>3</sub> into *p*-bromostyrene, b<sub>0</sub>, 88°, d<sub>20</sub> 1.100, n<sub>D</sub> 1.5933, which polymerizes quite rapidly (d after 6 days 1.126) and forms a dibromide, m 61° *Di-Et p-phenylbenzylmalonate* (yield, 65%), b<sub>0</sub>, 215°, free acid, m 185° ( $\alpha$ -Br deriv, m 133-5°), *bromohydrocinnamic acid* (II), m 140°, *p*-*phenylcinnamic acid*, m 225° (I ester, m 56°, forms a dihydrazones, m 128°, giving with hot alc KOH *biphenylpropionic acid*, m 165°) (*p*-*Phenylphenylalanine*, from II and concd NH<sub>4</sub>OH in sealed tubes at 100°, m 240) *Di-Et (1,5-dimethylbenzyl)malonate*, b<sub>0</sub>, 115-80°, free acid, m 135°,  $\alpha$ -Br deriv and *bromohydrocinnamic acid*, oils, *cinnamic acid*, m 125°  $\alpha$ -C<sub>10</sub>H<sub>7</sub>CHCl, m 80, obtained in 55% yield from C<sub>10</sub>H<sub>8</sub>, 5 parts concd HCl and 0.8 part formalin treated 10 hrs at 60-70° with HCl gas gives almost 80% C<sub>10</sub>H<sub>7</sub>CH(CO<sub>2</sub>Et)<sub>2</sub>, free acid, m 160°  $\alpha$ -Br deriv, m 155°, C<sub>10</sub>H<sub>7</sub>CH<sub>2</sub>CHCO<sub>2</sub>H, m 200,  $\alpha$ -*naphthacrolein* (precipd in 10% yield through the chloride, b<sub>0</sub>, 140°, and anilide, m 212°, light yellow b<sub>0</sub>, 160-10 m 18° (oxide, m 152° *semicarbazone*, light yellow, m 152° *acetylphenol condensation product* C<sub>10</sub>H<sub>7</sub>CH<sub>2</sub>CH(C<sub>6</sub>H<sub>5</sub>)CH(OH)Ph, deep yellow, m 117°) C A R

**Michael condensation** I Behavior of diethyl phenylmalonate in the Michael condensation Ralph Connor J Am Chem Soc 55, 1597 (1933) PhCH(CO<sub>2</sub>Et)<sub>2</sub> does not undergo the Michael condensation In EtOH EtCO and PhCHCOEt were formed and the latter condensed with  $\alpha,\beta$  unsatd ester or ketones In other media the only product isolated was a small amt of a cyclohexene deriv, C<sub>10</sub>H<sub>10</sub>(O)<sub>2</sub>, m 235, formed in CH<sub>2</sub> by the condensation of PhCHCOEt with 2 mols of benzilacetophenone (II) I was also precipd from Et  $\alpha$  3 diphenyl  $\gamma$  benzoylbutyrate and II with Na in CH<sub>2</sub>Cl  $\alpha$  phenyl  $\beta$  methylglutarate, b<sub>0</sub>, 130-5°, di-Et  $\alpha$  phenyl  $\beta$  dimethylglutarate, b<sub>0</sub>, 137-9° C J West

Wm H Adolph

**Benzyl compounds of  $\alpha$ -hydroxy acids and their use in synthesis** I Derivatives of glycolic acid Hermann O I Fischer and Bruno Golik Helv Chim Acta 16, 1130 (1933) Attempts to prep ester like compds of HO acids by the aid of carbomethoxylated  $\alpha$  HO acid chlorides failed, in that, even in dil NH<sub>3</sub> solns, the difference between the resistance to hydrolysis of the protecting group and the peptide linkage was not sufficiently great to prevent total cleavage and consequent regeneration of the starting materials By employing the acid chlorides of *O*-benzylated HO acids and by removing the PhCH<sub>2</sub> group by catalytic hydrogenation in the presence of Pd (C A 26, 2704) various esters of glycolic and other HO acids have been precipd which may have biol significance To 20 g Na in 400 cc warm PhCH<sub>2</sub>OH was added gradually 30 g ClCH<sub>2</sub>CO<sub>2</sub>H in 30 cc PhCH<sub>2</sub>OH and the mixt was heated at 150° for 4 hrs After concn, extn with Et<sub>2</sub>O, and acidification with concd HCl the free acid was extd with Et<sub>2</sub>O The dry ether soln was evapd and on fractionation at high vacuum gave 53 g (75%) of *benzylglycolic acid* (I), C<sub>9</sub>H<sub>10</sub>O<sub>3</sub>, b<sub>0</sub>, 136° Treatment of 17 g of I in CHCl<sub>3</sub> with 20.7 g PCl<sub>5</sub> and removal of

the solvent and excess reagent produced a crude product which was distd rapidly at high vacuum and yielded 13 g (78%) of *benzylglycolyl chloride* (II), C<sub>9</sub>H<sub>9</sub>ClO<sub>2</sub>, b<sub>0</sub>, 81°, anilide, C<sub>11</sub>H<sub>11</sub>NO, m 19° Two g glycolic acid in 20 cc dry CHCl<sub>3</sub> was shaken in the cold with 1.1 mols of PhNMe and 1 mol of II and stood for 24 hrs at room temp After washing, drying and removing the CHCl<sub>3</sub>, the neutralized AcMe soln of the product was extd with Et<sub>2</sub>O and acidified with concd HCl The dried ether oil was evapd and on fractionation gave 2.15 g (36%) of *benzylglycolylglycolic acid* (III), C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>, b<sub>0</sub>, 151°, m 79° One g Pd catalyst (C A 14, 1358) suspended in 10 cc glacial AcOH contained in a laking duck was satd with H and 1.68 g of III in 30 cc glacial AcOH was introduced The material absorbed 182.2 cc of H (calcd for II, 185.3 cc) at 761 mm and 15° The reduced material was filtered, freed from AcOH and yielded 0.8 g (80%) of thick prisms of *glycolylglycolic acid*, C<sub>4</sub>H<sub>6</sub>O<sub>4</sub>, m 97.9° (Ann 312, 146 (1900)) A similar catalytic reduction of 1 g of monobenzylglycolyl  $\beta$ -D-fructofuranose, prepd from II and  $\beta$ -D-fructofuranose (C 1 24, 3757), produced 0.6 g (77%) of monoglycolyl  $\beta$ -D-fructofuranose, C<sub>10</sub>H<sub>16</sub>O<sub>8</sub>, m 128° Similarly were produced  $\alpha$ -glycolylglycerol, *triglycolylglycerol*, *triglycolylmonosaccharoneglucose*, *triglycolylglucose* and *pentaglycolylglucose* but only in an oily or amorphous state These compds were estimated either by an alkalimetric detn of the introduced glycolic acid residue or by the formation of definite derivs by the complete acetylation or benzylation of the poly HO combination product C R Addinall

**Lichen substances XXXI Constituents of some Usnea species, with special reference to the compounds of the salazinic acid group** (1) Yashiko Asahina and Iyo taro Fukumoto Ber 66B, 1255-65 (1933), Cf C 1 27, 3318 The thalli are exhausted with boiling ether, the ext is evapd and the residue extd with hot benzene (soln 1 and residue B) The thalli, freed from ether sol constituents, are then extd with hot acetone and the ext is concd, if the lichen contains salazinic acid (I) the product which seps at this point is exhausted with ether, which leaves a residue C Soln 4 on concn usually yields a mixt of ummic acid (II) and atranorin (III), sepd by treatment with alc NaOAc in which only II is sol Residue B on purification gives protoctetraric acid, C<sub>14</sub>H<sub>16</sub>O<sub>6</sub> (IV), having all the properties of ramalinic acid From eq acetone it seps sometimes with, sometimes without, 1 mol H<sub>2</sub>O which is very firmly held and cannot be at once removed at 110°, that it is water of crystn is shown, however, by the formation of an anil C<sub>14</sub>H<sub>16</sub>O<sub>6</sub>NPh, m 225° (decomps) On long boiling with EtOH, IV is converted into cetraric acid, C<sub>12</sub>H<sub>14</sub>O<sub>6</sub> (V), while MeOH gives a protoctetraric acid Me ether (VII), which in all probability is identical with Hesse's methylprotoctetraric acid (J prakt Chem 70, 465) Catalytic hydrogenation gives hypoprotoctetraric acid, C<sub>14</sub>H<sub>18</sub>O<sub>6</sub> Residue C from lichens free from I is a neutral product (VIII), m around 211°, whether it is closely related to or perhaps even identical with Hesse's barbatin (Ann 284, 169) has not yet been detd Residue C from those lichens whose thalli give a red or rust-red color with alkali consists either of I or its Me ether (IX) That I in its reduction to hyposalazinic acid may also give hypoprotoctetraric acid has been confirmed *Usnea montis Fuji* (Motyka), whose thallus gives with KOH a deep yellow color soon becoming blood-red, gave 0.17% III, 0.53% II, IV and 4.2% I *U florida* Hoffm & perplexans Wm, whose marc gives a red KOH reaction, yielded 0.8% II, barbatin $\alpha$  acid (X), 0.27% IV and 3.77% I A species of *Usnea* from Java belonging to the *longissima* group and giving a KOH reaction similar to that of *U montis Fuji* yielded 1.7% II, IV(?) and 6% IX, which decomps 210-20°, is insol in NaHCO<sub>3</sub> sol in alkalis with yellow color changing to red-brown, gives a purple color with alc FeCl<sub>3</sub>, and forms a yellow anil and an acetate, m 227°, which gives no color with alc FeCl<sub>3</sub> *U longissima* Ach from Japan, whose thalli give a neg color reaction with KOH, yielded 1% II, 1% X, and 0.5%

VIII, which gives no color in alk with either  $\text{FeCl}_3$  or bleaching powder.  $\text{L. longissima}$  from Europe gave 3% II, 0.8% X and 0.1% VIII. A species of Japanese *Usnea* stands morphologically between *L. longissima* and *L. montis Fuji* and whose thallus gives a distinctly yellow, but not red, color with KOH yielded 1.2% II, 0.7% X, 0.6% III and 0.3% VIII. The lichen from Jesso which had been designated *L. trichodes* (C A 21, 2262) really belongs to the *longissima* group; its thallus gives only a light yellow color with KOH. This lichen yielded 5.6% II, cvermic acid and VIII. C A R

**Ursolic acid.** II. Oxidation of ursolic acid and its derivatives with chromic acid. S. Kikawa and I. Matsukawa. *J. Pharm. Soc. Japan* 53, 593 (1933), (C A 27, 192). K and M oxidized ursolic acid (I) and its derivs. with  $\text{CrO}_3$  and obtained various ketone compd., through which mutual relations of these compd. are explained. Oxidation of I with  $\text{CrO}_3$  in  $\text{AcOH}$  gave ursonic acid (II), m 251°, monoxime, m 216° semicarbazone, decomp. 209°. A small amt of a neutral compd., probably ursonic lactone, m 228°, was obtained as by-product. I and  $\text{CH}_3\text{N}$  gave 21 ml of Me ester, one (III), m 230°, 1 mol of m old AcMe, the other (IV), m 172°, 1 sol in AcMe. On oxidation with  $\text{CrO}_3$  both these compd. gave the same monoketone, Me ursinate (V), m 193.5°, which was previously described by Jacobs and Fleck (C A 25, 468). Oxime, m 211.2°. II and  $\text{CH}_3\text{N}$  also gave V. J considered that the ester m 110.20° and 1 sol in AcMe was the pure compd., while the one m 230° and 1 sol in AcMe was an impure product. Oxidation of III with  $\text{CrO}_3$  equiv. to 3 O, or by Kiliams reagent gave a ketone Me ester,  $\text{C}_{30}\text{H}_{48}\text{O}_2$ , m 190°. J et al. obtained by means of Kiliams reagent a diketone,  $\text{C}_{30}\text{H}_{46}\text{O}_2$ , m 161°. Oxime m 210.11°. The diketone was obtained by K and M as follows. I and AcO gave acetylursolic acid, m 291°, which was oxidized with  $\text{CrO}_3$  equiv. to 1 atom O to ketacetylursolic acid (VII), m 290.7°, monoxime, m 249.500° phenylhydrazine, m 300° semicarbazone, m 284° (decomp.). Sapon of VII with 10% KOH gave ketoursolic acid, decomp. 278.80°, monoxime, m 261.6°. VII and  $\text{CH}_3\text{N}$  gave Me ketacetylursolate (VIII), m 212.4°, monoxime, m 228.30°. VIII was also obtained by oxidation of Me acetylursolate (IX), m 216.7° which was in turn obtained from IV and AcO. Sapon of VIII with 10% KOH gave Me ketoursolate (X), m 162°. Oxidation of X gave Me ketoursolate (XI), m 196.1°, 1 sol in MeOH, 1 sol in  $\text{CHCl}_3$  dioxime m 211.2°. The dioxime of Jacobs diketone m 210.11°. This discrepancy can be explained by assuming that K and M's dioxime exists in anhyd form. To clarify this point, the mono phenylhydrazine, decomp. 231.6°, was obtained from XI. This was reduced by  $\text{Na}$  to the phenylpyrazole deriv., m 24°. From this it is concluded that XI is a  $\beta$  diketone having a  $\text{COCH}_2\text{COMe}$  group. Oxidation of VI with excess  $\text{CrO}_3$  gave ketacetyldehydroursolic acid (XII), decomp. 30°, oxime, decomp. 355°. XII and  $\text{CH}_3\text{N}$  gave Me ketacetyldehydroursolate (XIII), m 239.41°, which was also obtained from IX by oxidation, oxime, m 213°. Sapon of XIII with 10% KOH gave Me ketodehydroursolate (XIV), m about 135°. Sapon of XII gave impure ketodehydrouronic acid which on methylation gave XIV. By a diagram mutual relationships of these compds. are explained. Nao Y et al.

**Preparation of depsides by means of azides.** Rodolfo O. Pepp. *Notas sobre quim. Argentina* 21, 53 (1933) (C A 24, 4295).—Me gallate was prepd. as in Beilstein, Ld. 4, 10, 483. This was converted into the tri Me deriv. as in Ber. 35, 2544. By use of the method of Beilstein, Ld. 4, 10, 484, for other hydrazides, trimethylgalloyl hydrazine was prepd. The latter forms a characteristic ketone deriv. with acetone. By use of the method of J. prakt. Chem. [2] 52, 240 (1895), for other azides, trimethylgalloylazide was prepd. I. M. Symmes.

**Synthesis of dihydroisosthol.** Constitution of osthol. Masataro Yamashita. *Bull. Chem. Soc. Japan* 8, 276-80 (1933).—The condensation of resorcinol with isocyanitrile by the Hoesche reaction yielded a crude reaction

product hydrolyzed to an only substance (I) forming an oxime, 2,4-dihydroxyphenyl isobutyroline,  $\text{C}_{11}\text{H}_{11}\text{NO}_3$ , m 203.5°, identical with that of the corresponding ketone prepd. by Bohme (C A 20, 2320). I was reduced to 2,4-dihydroxyisobutylbenzene, converted by the Pechmann reaction into 6-isobutyl-7-hydroxycoumarin,  $\text{C}_{14}\text{H}_{14}\text{O}_3$ , m 104.10°. Methylation with  $\text{CH}_3\text{N}$  or with MeI and MeOH KOH yielded 6-isobutyl-7-methoxycoumarin (II),  $\text{C}_{15}\text{H}_{14}\text{O}_3$ , m 61.2°. This in p differs by about 20° from that of dihydroosthol. The constitution of dihydroosthol appears therefore to be different from that suggested by Butenandt (C A 26, 3796), a fact supported by the recent work of Spith and Peete (C A 27, 5712). II has been designated dihydroosthol. C A R

**Reaction between some acid chlorides and esters.** I. P. Kyrides and M. N. Dvonikoff. *J. Am. Chem. Soc.* 55, 1630 (1933). I gumol amts of phthalyl chloride and diethyl phthalate react in presence of traces of  $\text{ZnCl}_2$  to give excellent yields of  $\text{C}_6\text{H}_4(\text{CO})\text{O}$  and  $\text{EtCl}$ , other alkyl esters of  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})$  react similarly, except that the yields of the alkyl chlorides are lower because of the formation of larger amts of alkynes. Succinic esters and succinyl chloride react in the same manner.  $\text{BzOEt}$  and  $\text{BzCl}$  react with  $\text{ZnCl}_2$  at higher temps. to give fair yields of  $\text{BzO}$  and  $\text{EtCl}$ .  $\text{BzCl}$  and phthalic ester react to give alkyl chlorides and presumably a mixt. of the anhydrides of the acids is the main reaction product. The same is true of the reaction of phthalyl chloride and  $\text{BzOEt}$ . C J West.

**Tautomerism of phthalyl bromide.** Wm. Davis, Arthur N. Hambley and Geo. S. C. Summers. *J. Chem. Soc.* 1933, 1509-15. Cryst. phthalyl bromide, b 191°, b 134°, m 78.81°, d<sub>4</sub> 1.509, results from  $\text{C}_6\text{H}_4(\text{CO})\text{O}$  and PBr or PBr<sub>3</sub> at 100° for 24 hrs. and then at 100.6° for 36 hr. or from  $\text{C}_6\text{H}_4(\text{COCl})$  and HBr at 150.60° for 2 hrs., a study of its rates of reaction with iso-PrOH shows it to have the cyclic formula. When melted and heated to 90° it exists as the acyclic compd., as is shown by parachor data, and the rate of reaction with iso-PrOH and PhNH<sub>2</sub>. The 2 forms are tautomeric. The iside could not be prepd. C J West.

**Autooxidation of  $\alpha,\beta$  unsaturated ketones.** VII. W. Feib. *Ber.* 66B, 118, 92 (1933) (C A 27, 346). The autooxidation of camphor and piperitone in alk. alk. has been shown to consist in addn. of mol. O to the ketone, cleavage of  $\text{H}_2\text{O}$  from the addn. product, oxidation of unchanged ketone to the keto oxide by this  $\text{H}_2\text{O}_2$ , and rearrangement of the oxide on addn. of alk. at the oxide union under the catalytic influence of the alkali. The study has now been extended to other similar ketones. The oxide (I) of 3-methylcyclohexanone (II), prepd. according to Weitz and Scheller (C A 16, 1252), b 201.2°, d<sub>4</sub> 1.07,  $n_D^{20}$  1.4621, gives with KOH in boiling MeOH an unstable addn. product (III) which immediately loses  $\text{H}_2\text{O}$  to form the ether (IV), b 220°, d 1.040,  $n_D^{20}$  1.4844. The same ether is formed by autooxidation of II. Similarly the oxide, b 212.15°, d<sub>4</sub> 1.07,  $n_D^{20}$  1.4630, of 3,3-dimethylcyclohexanone, forms an ether, b 228.80°, d 1.011,  $n_D^{20}$  1.4798, also obtained by autooxidation of the ketone. Carvotanacetone behave like camphor. The oxide, b 118.20°, d 1.0129,  $n_D^{20}$  1.4355, in part rearranged by KOH in MeOH into the unstable hydroxy-carvotanacetone, m 181°, and in part adds MeOH to form the ketoglycol Me ether,  $\text{C}_{11}\text{H}_{16}\text{O}_3$ , b 143.30°, d<sub>4</sub> 1.052,  $n_D^{20}$  1.4130, both of which are also obtained by autooxidation of the ketone. Carvotanone react just like piperitone. The oxide, b 118.22°, d<sub>4</sub> 1.001,  $n_D^{20}$  1.4811, heated 20 min. with excess of alkali in MeOH, gives the H<sub>2</sub>O acid  $\text{C}_{10}\text{H}_{16}\text{O}_3$ , m 78°, obtained from piperitone, and in iso-meric acid, m 114.15°, which strongly depresses the m p of the acid of the same m p obtained from piperitone, forms no lactone but loses  $\text{H}_2\text{O}$  on short heating with 20%  $\text{H}_2\text{SO}_4$ , giving an unsat. acid  $\text{C}_{10}\text{H}_{14}\text{O}_2$ , b 216.5°, d<sub>4</sub> 1.006,  $n_D^{20}$  1.4735, which, from its const., is closely related to, perhaps identical with, carvonic acid. If an excess of  $\text{H}_2\text{O}$  is used in prepg. the oxide of the autooxidation is carried out in hot soln., the oxide

is further oxidized to the tertiary alc.  $C_9H_{16}O$  which, however, unlike the isomer from piperitone, splits off  $H_2O$  in the alk. soln., giving the yellow hydrocarbon  $C_9H_{14}$ ,  $b_{20}$  50° 5',  $b$  152° 8',  $d_{20}^{20}$  0.840,  $n_D^{20}$  1.4758. Carvone, although it readily absorbs 1 mol.  $O_2$  in alk. alc., is converted by  $H_2O_2$  only with difficulty into the oxide,  $b_{20}$  105–10°,  $d_{20}^{20}$  1.020,  $n_D^{20}$  1.4823, which in boiling alk. MeOH slowly adds MeOH to form the ketoglycol *Me ether*,  $b_{20}$  135–7°,  $d_{20}^{20}$  1.034,  $n_D^{20}$  1.4727. If the ketone in alk. MeOH is treated rapidly and without cooling with 1 mol.  $H_2O_2$  there is obtained a small amt. of a cryst. substance  $C_{20}H_{32}O_3$  (formed in greater yield (up to 15%), together with the above ether, by autooxidation of the ketone), consisting of a mixt. of 2 isomers,  $m$  215° and 217° (mixed  $m$ . p., 180°), sepd. by cautious crystn. from warm dil. MeOH or AcOEt. Each forms a semicarbazone, decomp. 260° and 254°, resp., and is exceedingly stable toward chem. agents ( $KMnO_4$ , Br,  $H$ ). They are probably formed by aldol condensation of the oxide, with elimination of  $H_2O$ , and are possibly cis-trans isomers, differing from each other in the relative positions of the 2 rings united by a double bond. The main product of the autooxidation of the ketone is an alkali-sol brown resin  $C_{20}H_{32}O_3$ . *l*-Verbenone oxide,  $b_{20}$  118–20°,  $d_{20}^{20}$  1.063,  $[\alpha]_D^{20}$  –105.6° (semicarbazone, decomp. 216°), with hot alc. KOH very slowly yields 10.5% of the isomeric hydroxyverbenone,  $m$  119–21° (semicarbazone,  $m$  191°; acetate,  $b_{20}$  158–60°,  $d_{20}^{20}$  1.078,  $n_D^{20}$  1.4875). The HO compd. is very stable in alk. soln., but in solid form or in neutral or acid soln. it is changed extremely rapidly by  $O$ . Alc. cannot be added to the oxide under the influence of alkali. The ketone in alk. alc. readily absorbs 1 mol.  $O_2$ ; a small amt. of the oxide is present in the volatile part of the product. Unlike the other ketones described above, isophorone is difficultly autooxidizable although it is easily and completely converted into the oxide,  $b_{20}$  208–11°,  $d_{20}^{20}$  0.998,  $n_D^{20}$  1.4591 (semicarbazone, decomp. 216°), which with alc. MeOH gives, together with a little of the colorless hydroxyisophorone,  $m$  92–3°, chiefly the *Me ether* of the latter,  $b$  221–3°,  $d_{20}^{20}$  0.971,  $n_D^{20}$  1.4803, which is hydrolyzed to the HO compd. by  $HCl$  AcOH on the water bath, and is formed in the slow and incomplete autooxidation of the ketone. *Pulegone oxide*, formed from the ketone by long continued action of  $H_2O_2$  in the presence of alkali and the min. amt. of water,  $b_{20}$  125–7°,  $m$  40°,  $d_{20}^{20}$  1.008,  $[\alpha]_D^{20}$  6.6°,  $n_D^{20}$  1.4670, is very slowly hydrolyzed by alkali to acids, without adding alc. The ketone autooxidizes slowly and incompletely; the high  $d$ . of the higher-boiling, volatile neutral part of the product and its high  $O$  content point to the formation of the oxide. The addn. of alc. under the influence of alkali, to all the  $\alpha,\beta$ -unsatd. ketone oxides (except those of verbenone and pulegone) thus far studied, always occurs in such a way that the alkoxy group adds to the C atom adjacent to the C=O group. If the newly formed HO group is tertiary,  $H_2O$  at once splits off. One or 2 long side chains (Ph, amyl, cinnamyl) in the 3- and 5-positions do not materially decrease the autooxidizability of the ketones but do make their conversion into the oxides more difficult or impossible. Like piperitone, the ketones which are easily converted into the oxides by alk.  $H_2O_2$  (carvone, isophorone, verbenone) are also slowly converted into the oxides by  $H_2O_2$  in neutral alc. soln. Mineral acids catalyze the action of  $H_2O_2$  somewhat less than alkali, yielding chiefly keto glycols.

Neutral products of oxidation of pinene. II. K. Jawiński and W. Zacharewicz. *Roczniki Chem.* 12,

854–61 (1932); cf. *C. A.* 26, 5933. The fraction,  $b_p$  88–97°, of the neutral oxidation products of pinene yields norpinic acid, originating from pinonaldehyde, and a dibromide,  $C_{10}H_{16}O_2Br_2$  (I),  $m$  116°, on treatment with NaOBr; with NaOH the products are pinonic acid and a keto-alc.,  $C_{10}H_{16}O_3$  (II),  $m$  35°,  $b_p$  98–9° (semicarbazone,  $m$  204°, *l*- and *l*-benzylidene derivs.,  $m$  78–9° and 98°), which is also obtained by eliminating Br from I. Since pinene glycol yields *l*-pinonaldehyde on oxidation with  $K_2Cr_2O_7$  it is concluded that the original neutral fraction consists of pinene glycol, *l*-pinonaldehyde and II. B. C. A.

**Camphenilone and its derivatives.** Pascal Snitter. *Bull. inst. pin* 1933, 178–80, 200–11. Prep'n of camphenilone (I) by Komppa and Hintikka's method (*C. A.* 6, 1594) by oxidation of camphene with  $N_2O$  is long, tedious and expensive, and, contrary to K. and H., who claimed a 90% yield, S. could not obtain more than a 60% yield. The technique was modified by generating the  $N_2O$  by action of  $HNO_3$  and  $O_2$  on  $As_2O_3$  (instead of starch) and dehydrating the gas before passing into a petr. ether soln. of camphene. Almost complete oxidation of 150 g. camphene could thus be readily obtained in 6 hrs. and produced 65% of I,  $m$  (after rectification under vacuum in a Dupont column) 37°,  $b$  192°,  $b_{16}$  81°,  $d_{20}^{20}$  0.980,  $n_D^{20}$  1.469, mol. refraction 39.5 (calcd. 39.5) (semicarbazone  $m$  221°); at 37° it dissolves nitrocellulose to form a homogeneous paste. The structural formula given by Lipp (*C. A.* 7, 3739) was confirmed. Attention is drawn to the advantages of I as a f.-p. solvent; its f.-p. const. is about 600 (as compared with 39 for AcOH). The Raman spectrum is given. Reduction of I by Na and alc. gives camphenylol (II) together with a small amt. of pinacol; attempts to hydrogenate I in presence of Pt black were unsuccessful. II gives with  $PCl_5$  90% of camphenyl chloride,  $m$  54°,  $b_{16}$  70–6°. Camphenylene, obtained in 38% yield by reduction of II by  $EtONa$  at 120°,  $m$  26.5°,  $b$  138–40°, contains no santal (contrary to Meerwein, *C. A.* 8, 3183 and Komppa and Hintikka). The Raman spectra of camphenylene and of apobornylene are given, and show that the camphenylene obtained was practically pure, contg. only about 2.5% apobornylene. A Papineau-Contour.

**Synthetic camphor.** V. I. Tishchenko and G. A. Rudakov. *Lesokh. Prom.* 1, No. 5–6, 24–5 (1932). A review dealing particularly with research carried out in Russia. A. A. Bahtlingk.

**The preparation of camphor by the dehydrogenation of borneol and isoborneol with metallic catalysts.** F. K. Sivov, M. M. Korotueva and M. P. Kochueva. *J. Chem. Ind. (Moscow)* 1933, No. 3, 52–6. Cu and CuO are poor catalysts for this reaction. The best catalyst is Ni, prep'd. by grinding intimately sulfate-free  $Ni(OAc)_2$  and wood charcoal and reducing. Borneol is dissolved in 6% of its wt. of xylene and 250% paraffin, and 1% alkali is added. The mixt. must be free from  $H_2O$ . The catalyst is added in portions at 250–60°, with stirring. The yields are 85% and are somewhat better with isoborneol. H. M. Leicester.

**Optical isomerism and blood-pressure-lowering action.** Julius v. Braum and Anni Jacob. *Ber.* 66B, 1161–4 (1933). *d*-Rotatory fenchone,  $[\alpha]_D^{20}$  53.18° (the optically homogeneous compd. has  $[\alpha]_D^{20}$  65°), was converted with  $NaNH_2$  into the fencholic amide and thence with Br and alkali into the fenchyl isocyanate,  $[\alpha]_D^{20}$  2.5° (pure compd., 3.04°), which with  $Me_3NCH_2CH_2OH$  yielded the carbamate  $C_{10}H_{17}NHCO_2CH_2CH_2NMe_3$ ,  $b_{16}$  168–71°, and this with MeI in a little MeOH gave the choline deriv.  $C_{10}H_{17}NHCO_2CH_2CH_2NMe_3I$  (I),  $m$  74°,  $[\alpha]_D^{20}$  5.18° (MeOH). *l*-Rotatory fenchone was prep'd. from thuja oil and freed from a persistently adhering impurity by treatment with a little  $NaNH_2$  in benzene; it  $m$  5.2°,  $[\alpha]_D^{20}$  –66.8°,  $d_{20}^{20}$  0.9484, and was therefore quite pure. It yielded, like the *d*-rotatory compd., a fencholic amide,  $m$  94°,  $[\alpha]_D^{20}$  –5.85° (MeOH), –6.67° (benzene) (the *l*-fencholic acid prep'd. from this amide  $b_{16}$  144–5°, solidifies 16–18°,  $d_{20}^{20}$  0.9739 (0.9762),  $[\alpha]_D^{20}$  –3.61° to –3.66°; chloride,  $b_{20}$  118–19°,  $d$  1.0050,  $[\alpha]_D^{20}$  4.04°; *Et ester*,  $b_{20}$  115–17°,

d, 0.9115,  $[\alpha]_D^{25} = -3.753^\circ$ ). *Fenchyl isocyanate*,  $b_{12}$  82-3°,  $[\alpha]_D^{25} = -2.96^\circ$  (without solvent). *Choline deriv.* (II) (antipode of I), m. 75°,  $[\alpha]_D^{25} = -6.39^\circ$  (MeOH). Both I and II lower the blood pressure, I less than II. They also increase the peristalsis of the smooth musculature of the earthworm, I at a diln. of 1:50,000 and II only at 1:1000. Moreover, as I was not optically homogeneous and was about 20% racemized, the ratio of the physiol. activity of the 2 pure optical isomers must be even greater than 50:1. C. A. R.

**Stereochemistry of biphenyls.** XXXIV. 2,2',4,4',5,5',6,6'-Octamethylbiphenyl-3,3'-disulfonic acid and biphenyl-3,3'-disulfonic acid. A. E. Knauf and Roger Adams. *J. Am. Chem. Soc.* 55, 4704-9 (1933); cf. C. A. 27, 5734.-2,4,5,6-Me<sub>4</sub>C<sub>6</sub>HBr and Mg give 21% of 2,2',4,4',5,5',6,6'-octamethylbiphenyl (bisoduryl) (I), m. 121.2°; with ClSO<sub>3</sub>H at 0° there results 77% of the 3,3'-disulfonfyl chloride, m. 150-60°; the free acid was resolved by strychnine; the less sol. distrychnine salt m. 248-51° (decompn.),  $[\alpha]_D^{25} = -21.3^\circ$ ; the more sol. salt had  $[\alpha]_D^{25} = -10.3^\circ$ ; the *l*- and *d*-NH<sub>4</sub> salts had  $[\alpha]_D^{25} = -11.4^\circ$  and  $11.2^\circ$ , which showed no change on continued boiling. I and ClCH<sub>2</sub>COCl with AlCl<sub>3</sub> give the 3,3'-dichloroaceto deriv., m. 183-4°; the 3,3'-diaceto deriv. m. 184°; attempts to replace these groups were unsuccessful. Biphenyl-3,3'-disulfonic acid could not be resolved; *brucine salt*, m. 268-70°,  $[\alpha]_D^{25} = -25.3^\circ$ ; *strychnine salt*,  $[\alpha]_D^{25} = -30^\circ$ . C. J. West

**Syntheses in the bi- and terphenyl series.** II. Julius v. Braun, Gerhard Irmsch and Johannes Nelles. *Ber.* 66B, 1471-83 (1933); cf. C. A. 21, 2470.—The attachment of the *p*-PhC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub> group (I) to N and S is strikingly less firm than that of PhCH<sub>2</sub> (C. A. 18, 1830). To determine what influence the lengthening of the chain by another Ph residue to *p*-(*p*-PhC<sub>6</sub>H<sub>4</sub>)C<sub>6</sub>H<sub>4</sub> (II) and hydrogenating 1 or 2 aromatic residues in I and II would have on the firmness of attachment of these groups, the following compds. have been prep'd. (all substituents in the *p*-position): C<sub>6</sub>H<sub>5</sub>Ph (III), C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>X (X = Cl or Br) (IV), PhC<sub>6</sub>H<sub>4</sub>Ph (V), PhC<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>X (VI), C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>Ph (VII), C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>X (VIII), C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>Ph (IX), C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>X (X). *p*-Cyclohexylbenzaldehyde (XI) was obtained in small yield in 3 ways: (1) III, AlCl<sub>3</sub> and CuCl in benzene treated 15 hrs. with CO + HCl gave 14-16% XI,  $b_{12}$  160° (semicarbazone, m. 220°; oxime, m. 88°; aniline condensation product (XII), m. 122°; acetone condensation product, faintly yellow, m. 77°). With alkali (Cannizzaro) XI gives *p*-cyclohexylbenzoic acid, m. 198°, and *p*-cyclohexylbenzyl alc.,  $b_{12}$  162°, m. 41°, also obtained easily from the chloride (IV, below) by treatment with AcOH-KOH and alk. sapon. of the resulting acetate,  $b_{12}$  184°, m. 47°. (2) III with ClCO<sub>2</sub>Et gives 30% of the ester C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Et, thick yellow oil,  $b_{12}$  215-25°; the free acid (48% yield), m. 111°, gives with PhNH<sub>2</sub> 50% XII which yields 6% XI (based on the III used). (3) III (3 mols.) allowed to stand 12 hrs. with 1 mol. anhyd. chloral and 0.25 mol. AlCl<sub>3</sub> gives 23% (based on the chloral) of the addn. product C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>CH(OH)CCl<sub>3</sub>, thick yellow oil,  $b_{12}$  215°, which is quite smoothly converted into XI by boiling satd. K<sub>2</sub>CO<sub>3</sub>. The most striking property of XI is its extraordinarily pleasant citral-like odor, which it loses on acetalization; the *di-Et acetal*  $b_{12}$  181°. Ph<sub>2</sub>, dry trioxymethylene and ZnCl<sub>2</sub>, treated in the cold with HCl gas, give about 20% *p*-PhC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>Cl,  $b_{0.3}$  130°, m. 68°, and 12% 4,4'-bis(chloromethyl)biphenyl, m. 136°,  $b_{12}$  235°; the latter with hot aq. alc. KCN gives the faintly yellowish dicyanide, m. 184°, with BzH the dibenzal deriv., decomp. 256°, and with hot HCl in sealed tubes at 130°, biphenyl-4,4'-diacetic acid, m. 270-3° (*di-Et ester*,  $b_{0.3}$  204-6°, m. 55°). Under the same conditions III gives 50% *p*-chloromethylhexahydrobiphenyl (IV, X = Cl), a viscous liquid oxidized by hot 30% HNO<sub>3</sub> in sealed tubes to *p*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> and converted by short treatment with NHEt<sub>3</sub> into the compd. C<sub>6</sub>H<sub>4</sub>(C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>NEt<sub>3</sub>)<sub>2</sub>,  $b_{0.1}$  125° (methiodide, m. 186°). The mixt. of *cis*- and *trans*-*p*-C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>OH obtained by condensing C<sub>6</sub>H<sub>5</sub>OH with PhOH and hydrogenating the resulting C<sub>6</sub>H<sub>5</sub>C<sub>6</sub>H<sub>4</sub>OH

yields quantitatively with 66% HBr in sealed tubes at 120° a mixt. of the *cis*- and *trans*-bromides,  $b_{12}$  150-5°, which with AlCl<sub>3</sub> in C<sub>6</sub>H<sub>6</sub>-CS<sub>2</sub> yields cyclohexylcyclohexene,  $b_{12}$  110°, a mixt.,  $b_{0.3}$  130-50°, of much *m*-C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>Ph with a little IX (as shown by dehydrogenation with Se at 300° to *m*-C<sub>6</sub>H<sub>4</sub>Ph<sub>2</sub> and 15% V), and a compd. *p*-(*m*-C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>, m. 145°, which gives pure *p*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> with HNO<sub>3</sub> and is dehydrogenated by Se to an isomer, m. 232°, of quinquephenyl. By treating 2 *p*-cyclohexylcyclohexanone in the usual way with PhMgBr, boiling the product with 20% H<sub>2</sub>SO<sub>4</sub>, brominating the resulting decahydroterphenyl (XIII),  $b_{12}$  225-30°, m. 97-8°, and heating the product at 180° under 6 mm. is obtained 70% hexahydroterphenyl (VII), which m. 85° and is dehydrogenated to V by Se. *p*-BrC<sub>6</sub>H<sub>4</sub>Ph is conveniently prep'd. in a similar manner: *p*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub> is treated with Mg activated with I and cyclohexanone and the product is boiled with 20% H<sub>2</sub>SO<sub>4</sub>, giving a little octahydroterphenyl, C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>, m. 110° (which is readily hydrogenated to *p*-C<sub>6</sub>H<sub>4</sub>(C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>, m. 101°), and tetrahydro-*p*-bromobiphenyl, C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>Br,  $b_{12}$  175-80°, m. 73°, which, brominated as above and heated *in vacuo*, yields pure *p*-BrC<sub>6</sub>H<sub>4</sub>Ph, m. 80°. This with Mg and cyclohexanone yields tetrahydroterphenyl which, however, cannot be completely freed of the carbinol even by boiling with H<sub>2</sub>SO<sub>4</sub> and is therefore treated in ether with HCl gas to replace the OH group by Cl, and HCl is split off with pyridine; the hydrocarbon, m. 146-8°, is now nearly pure and with Pd and H gives VII but in such poor yield that the method cannot compete with that described above for prep. VII. With Pd and H in acetone XIII gives a mixt. of dodecahydroterphenyl (IX), m. 86°, and a liquid stereoisomer (XIV)  $b_{0.2}$  144°, which rearranged practically completely into IX when heated 2 hrs. in CS<sub>2</sub> with 0.02 mol. AlCl<sub>3</sub> and, like IX, is smoothly dehydrogenated to V by Se. More energetic hydrogenation of XIII (with Ni and H at 200°) gives octadecahydroterphenyl (XV), also in 2 stereoisomeric forms: crystals m. 162° and 55-7°, resp. (this is also true of all the less highly hydrogenated derivs. of V and even of V itself); neither of the isomers can be rearranged into the other with AlCl<sub>3</sub>, however. Hexadecahydroterphenyl, prep'd. like XIII from *p*-cyclohexylcyclohexanone and C<sub>6</sub>H<sub>5</sub>MgBr,  $b_{12}$  190°, m. 111-13°, gives the 2 isomeric XV with Pd and H. Attempts to introduce the CH<sub>2</sub>Cl group into V were entirely unsuccessful and VII did not give much better results with the isomeric IX and XIV the reaction was more satisfactory; XIV with trioxymethylene, ZnCl<sub>2</sub> and HCl gas and subsequent treatment with NHEt<sub>3</sub> gave the base C<sub>22</sub>H<sub>17</sub>N (less than 10%),  $b_{0.4}$  185-90°. 4,4'-Dibromoterphenyl (85% from V in C<sub>6</sub>H<sub>5</sub>Cl<sub>2</sub> with 4 atoms Br and a little I), m. 312-13°; the mother liquors yield only little of the mono-Br compd. (XVI) which could also not be obtained in any appreciable yield by using only 2 atoms Br. *p*-Cyclohexylcyclohexanone with *p*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub> and Mg yields 45% 4-bromodecahydroterphenyl (XVII),  $b_{0.3}$  180-90°, m. 97-8°, which, treated in the cold with 2 atoms Br and then at 160° with 8 more atoms Br until the evolution of HBr ceases and distd. *in vacuo*, gives pure 4-bromoterphenyl (XVI), m. 230-2°; the mother liquors contain bromohexahydroterphenyl, m. 148°. Along with XVII is formed a little eicosahydroquinquephenyl C<sub>22</sub>H<sub>17</sub>(C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>,  $b_{0.7}$  250°, m. 240-5°. XVI is as resistant as V to HCHO and HCl. 4-Methyldodecahydroterphenyl C<sub>6</sub>H<sub>4</sub>(C<sub>6</sub>H<sub>4</sub>CH<sub>3</sub>)<sub>2</sub> (80% from *p*-MeC<sub>6</sub>H<sub>4</sub>MgBr and *p*-cyclohexylcyclohexanone), m. 108-10°,  $b_{0.7}$  165°, gives on hydrogenation a mixt. of stereoisomeric 4-methyldodecahydroterphenyls, m. 82° and 36-8°, dehydrated by Se to 4-methylterphenyl, m. 206-8° (76% yield), which is oxidized by CrO<sub>3</sub> to terphenyl-1-carboxylic acid, m. 305°, and converted by adding  $\frac{1}{4}$  mol. Br dropwise to the C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> soln. into 4-bromomethylterphenyl (VI, X = Br), m. 210° (70% yield); this with NHEt<sub>3</sub> gives the base PhC<sub>6</sub>H<sub>4</sub>C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>NEt<sub>3</sub>, m. 133°. C. A. R.

**Preparation of *p*-nitrophenetole from *p*-nitrochlorobenzene.** II. Shinjiro Aoyama and Kozo Nanai. *J. Pharm. Soc. Japan* 53, 613-22 (1933).—In the 1st paper (*Bull. Imp. Hyg. Lab.*, Tokyo 42, 235 (1933)) the authors

stated that among many catalysts investigated, the mixt of  $MnO_2$  and  $Co_2O_3$  (I) was the most suitable. This paper deals with the influence of various factors such as concn of alkali or alk on the yield and purity of the product. By the proper use of I the reaction can be so controlled that the side reactions are suppressed and the main reaction is augmented to make the process a tech possibility. I can be used repeatedly. The amt of I to be used depends mainly on the concn of alk and to some degree on the amt of alkali and the vol of alc. If 80% alc is used the concn of alkali ( $NaOH$ ) should be 4% or less; if the alkali is below 2.2 mols, the amt of I should be 10% of the  $p-O_2NC_6H_4Cl$  (II). If the alkali is increased to 2.7 mols, the amt of I is to be raised to 25%. If the concn of alkali is more than 80%, the formation of dichloroxybenzene is rapidly increased and 100% of I is required. The addn of  $Cu$ ,  $Fe$ , glycerol or  $NaOAc$  does not influence the speed of the reaction. If the concn of alkali is greater, the amt of alkali and the heating time can be lessened. I. g., when 95% alc is used, the heating time can be halved and only 80% of alkali is required as compared when 68% alc is used. An increase in the concn of alk increases the yield and purity of  $p-O_2NC_6H_4OH$  (IV), but decreases the yield of  $p-O_2NC_6H_4OH$  (IV), while increase in alkali and length of heating time increase the purity of III and the yield of IV but decrease the yield of III. Example. Heating for 15 hrs 200 g II, 110 g  $NaOH$ , 50% alc, 100 g  $MnO_2$ , 2 g  $Co_2O_3$  gave 92% of 98% pure III and 8% of IV.

**Preparation of nitroanisole from  $\epsilon$ -nitrochlorobenzene** S. Aoyama and J. Morita. *J. Chem. Soc. Japan* 53, 224 (1932). The authors studied the influence of various factors concerned in the prepn of 1,4- $NO_2$  (II) from 1,2- $NO_2$  (I) and  $p-O_2NC_6H_4Cl$  (II). In general the prepn of I is much easier than the prepn of 1,4- $NO_2$  (II) from 1,2- $NO_2$  (I) (see previous abstr.). If the reaction is carried on under ordinary pressure with nitric acid as catalyst, a suitable amt of dichloroxybenzene (III) is produced while the yield of I increases. By the use of the catalyst of  $Cu$  (part 1, 4) ( $CuCl_2$  + glycerol) or of the author's  $MnO_2$  +  $Co_2O_3$ , the formation of III is prevented. The most important factor is the concn of  $NaOH$ . The lowering of the concn of  $NaOH$  tends to retard the formation of  $p-O_2NC_6H_4OH$  (IV) but does not affect the yield and purity of I, the best concn being 8%. If the concn is more than 9%, the formation of III is increased. The amt of alkali ( $NaOH$ ) used should be 1.6 mols for 1 mol of II when the reaction is carried under pressure and 2.2 mol under ordinary pressure. If the amt of alkali is increased, the yield of I decreases but that of IV increases. The purity of I however increases with the increased amt of alkali as well as with the increased heating time up to 20 hrs, but its yield decreases. The heating time should be more than 20 hrs under ordinary pressure but 10 hrs if the reaction is carried under pressure at 70–80° for 3 hrs at 100°. Example A. Under ordinary pressure, 20 g II, 120 cc 95%  $MeOH$ , 11 g  $NaOH$ , 2 g  $MnO_2$  and 0.2 g  $Co_2O_3$  are heated 20 hrs to give 90% of 98% pure I and 10% of IV. Example B. 40 g II, 240 cc 95%  $MeOH$ , 11 g  $NaOH$  are heated at 70° under pressure to give 88% of 98% pure I and 2.5% of IV. N 1.

**Decomposition of basic and phenolic diphenylmethane derivatives and the synthesis of optically active aromatic compounds** II. Julius v. Braun, Ernst Anton, Werner Huesel, Gerhard Imrich, Robert Michaelis and Wilhelm I. uffert. *Ann.* 507, 143 (1933), cf. C. A. 23, 1687. PhAc (1 mol) and 2 mol  $PhOH$  with concd  $HCl$  gives, after 5 days, about 10% of dihydroxytriphenylmethane (I),  $m$  165°,  $b_p$  235–240° heating at normal pressure gives  $PhOH$  and  $p$ -hydroxydiphenylmethane (II) 18–90° ( $Ac$  deriv,  $b_p$  180–2°  $p$ -nitrobenzyl deriv,  $m$  70°), at 240° I absorbs more than 1.2 atoms  $H$ . Tetralone and  $PhOH$ , heated with concd  $HCl$  12 hrs at 100°, give about 10% of the phenol,  $C_{10}H_{10}O$   $b_p$  235–40° (1 g deriv,  $b_p$  240°). The  $Ac$  deriv,  $m$  252°, of the  $Me$ - $C_6H_4NH_2$  condensation product gives with  $HNO_3$ -

$H_2SO_4$  after 0.5 hr at 40° a  $di-NO_2$  compd,  $m$  190°, after 15 min there results a mono  $NO_2$  compd,  $m$  165°. Elimination of the  $Ac$  group gives the diaminodinitro compd (II), brown red,  $m$  214°,  $SnCl_4$  gives the tetra amine,  $m$  148° (phenanthrazine,  $C_{14}H_{10}N_4$ , yellow,  $m$  217° bis(methylbenzimidazol) compd,  $m$  225°). Elimination of the  $NH_2$  groups from II gives the  $m$ - $di-NO_2$  compd of 1,1-diphenylpropane,  $m$  101°  $m$ - $di-NH_2$  deriv,  $m$  125° ( $HCl$  salt,  $m$  150.5°,  $di$   $Ac$  deriv,  $m$  213°) through the diazo reaction there is formed  $m$ -dihydroxydiphenylpropane  $m$  114° ( $di$   $Bz$  compd  $m$  121°). The  $di$   $NO_2$  compd of the  $di$   $Ac$  deriv of the condensation product of  $PhNH_2$  and cyclohexanone  $m$  157° the free dinitrodiamino compd, brown,  $m$  245° reduction gives the tetraamino compd,  $m$  132° (phenanthrazine compd  $C_{14}H_{10}N_4$  yellow,  $m$  217°) removal of the  $NH_2$  groups gives the  $di$   $NO_2$  compd,  $C_{14}H_{10}N_4$ ,  $m$  113° reduced to the diamine,  $m$  147° ( $HCl$  salt,  $m$  150)  $di$   $Ac$  compd  $m$  214°  $Me$   $C(=O)$  and  $o$ - $Me$   $C_6H_4NH_2$  with  $HCl$  heated 10 hrs at 150°, give 40% of a methyl  $p$ -isopropylaniline  $b_p$  216° (monohydrate,  $m$  70.2°,  $HCl$  salt, only  $picrate$ ,  $m$  129°  $di$   $Ac$  compd,  $m$  201°) distn at 1 mm of the base with a very small amt of  $H_2SO_4$  gives  $o$ - $Me$   $C_6H_4NH_2$ , some mono  $m$ -isopropylaniline  $m$  132° ( $N$   $Ac$  deriv,  $m$  132°), and the dimer  $b_p$  233.5° ( $di$   $Ac$  deriv,  $m$  145°),  $di$  hydro deriv  $b_p$  215° ( $Ac$  deriv  $m$  164°)  $Me$   $C(=O)$  and  $o$ - $Cl$   $C_6H_4NH_2$  give 40% of the compd  $C_{14}H_{10}N_4$ ,  $b_p$  21° ( $Ac$  deriv,  $m$  149°) distn with a trace of  $H_2SO_4$  gives the dimer  $C_{18}H_{10}N_4$ ,  $b_p$  250.5° ( $Ac$  deriv  $m$  144°)  $Me$   $C(=O)$  and  $o$ -anisidine give 13% of the compd  $C_{14}H_{10}N_4$ ,  $b_p$  20.2° ( $HCl$  salt,  $m$  183°  $Ac$  compd only) the dimer,  $C_{18}H_{10}N_4$ ,  $b_p$  150.5°  $di$   $100^\circ$   $o$ - $H$   $NC_6H_4Ph$  and  $Me$   $C(=O)$  at 150° give at once the dimer  $C_{18}H_{10}N_4$  ( $Ac$  deriv,  $b_p$  260°)  $d$ -3-methylcyclohexanone and  $o$ -anisidine with 20%  $HCl$  and 1  $HOH$ , heated 200 hrs on the water bath or 8 hrs at 120° in a tube, give 10–20% of  $d$ -3-methylcyclohexenyl anisidine (III)  $b_p$  148.50°,  $m$  146° ( $HCl$  salt,  $m$  224°  $picrate$   $m$  162°  $Ac$  deriv,  $m$  80° dihydro deriv,  $b_p$  117.0°,  $m$  147° ( $Ac$  deriv,  $m$  51.3°  $HCl$  salt  $m$  233°) and 30–40% of dianisyl  $d$ -3-methylcyclohexane (IV),  $b_p$  240° ( $HCl$  salt,  $m$  215.7°) distn of IV with a little  $H_2SO_4$  gives III. Two preps prepd at 100° and 170° showed the following rotations at 20° (1  $HOH$  20.5°) III 12.01, 35.04 IV, 14.47, 10.10 III from IV, 10.01° 36.6° dihydro deriv of III  $b_p$  141.2°  $o$ - $Cl$   $C_6H_4NH_2$  gives 10% of methylcyclohexenyl chloroaniline,  $b_p$  158.60°,  $m$  53.70° ( $HCl$  salt,  $m$  184°  $Ac$  compd,  $m$  126°  $[\alpha]_D^{25}$  46.98° dihydro compd  $m$  17.20°  $[\alpha]_D^{25}$  1.57° ( $Ac$  compd,  $m$  97°  $[\alpha]_D^{25}$  5.99°) and 40% of methylcyclohexenyl chloroaniline  $b_p$  233.60°  $[\alpha]_D^{25}$  11.09°  $d$ -3-methylcyclohexenyl methyl lidine,  $m$  169°,  $[\alpha]_D^{25}$  -15.73° ( $HCl$  salt  $m$  236°  $picrate$   $m$  175°  $Ac$  compd,  $m$  176°)  $N$ -acetylcyclohexenylaniline and  $O_2$  give 50% of the ketoldehyde  $OH(C_6H_4)_2COC_6H_4NH_2$ ,  $m$  89–92° soln in  $Na_2CO_3$  gives the corresponding acid,  $C_{14}H_{10}O_4$   $m$  112° oxidation with  $KMnO_4$  or better with  $CrO_3$  gives the aminobenzo acid,  $C_6H_4O_2N_2$ ,  $m$  167°, giving with  $NaOH$  adipic acid. Reduction of the diazo compd gives the hydrazine,  $C_{14}H_{10}N_4$ ,  $m$  190.2°,  $BzNH_2$  gives the hydrazine  $m$  180°  $Ac$   $C_6H_4NH_2$ ,  $m$  185°. Oxidation of cyclohexenyl  $o$ -chloroaniline gives the acid  $C_{14}H_{10}O_4$ ,  $m$  151°. The compd  $MeC_6H_4C_6H_4NH_2$  on oxidation gives 25% of the  $Ac$  deriv,  $m$  110°, of the acid  $HO_2CCHMeC_6H_4CH_2CH_2CH_2CH_2CH_2NH_2$ ,  $m$  111° alkali fusion gives  $o$ -methyladipic acid. Oxidation of

cyclohexenylacetanilide with  $BzOH$  in  $CHCl_3$  gives the compd V, various fractions  $m$  from 142° to 214°, upon giving the oxide VI,  $m$  109° ( $Ac$  deriv,  $m$  142° quaternary iodide,  $m$  181°,  $picrate$ ,  $m$  167°)  $o$ -3-methyl-

NaOEt gave PhEtCHCH(CO<sub>2</sub>Rt)<sub>2</sub> (I), b<sub>p</sub> 154–6°; free acid (II) of I m. 70–70.6°. II on heating gave PhEt-CHCH<sub>2</sub>CO<sub>2</sub>H (III), b<sub>p</sub> 167 8°. III esterified and then reduced with Na and C<sub>2</sub>H<sub>5</sub>OH gave PhEtCHCH<sub>2</sub>CH<sub>2</sub>OH (IV), b<sub>p</sub> 135–8°. IV gave the bromide, b<sub>p</sub> 130 1°, which on treatment with NaCN gave the nitrile (V), b<sub>p</sub> 148 50°. Hydrolysis of V with concd. HCl gave the acid (VI), b<sub>p</sub> 185°, m. 104.5 5.5°. VI treated with SOCl<sub>2</sub> gave the acid chloride (VII), b<sub>p</sub> 138°. Cyclization of VII gave the tetralone (VIII), b<sub>p</sub> 148 50°; semicarbazone m. 183°. VIII by dehydrogenation with Se gave ethylnaphthol, m. 42°; picrate m. 152.5°. Julius White

**Catalytic dehydration of ionone and the constitution of ionone.** Marston T. Bogert and Victor G. Bourman. *J. Am. Chem. Soc.* 55, 4670 80(1933). Ionone (1,6-trimethyltetralin) (I) is conveniently prep'd. in excellent yield, by distn. of  $\alpha$ - or  $\beta$ -ionone with small amts. of I. Oxidation of I with KMnO<sub>4</sub> gives 43% of  $\beta$ -(2,4-dicarboxyphenyl)isovaleric acid (II), m. 220°, and 28% of  $\alpha$ -(2,4-dicarboxyphenyl)isobutyric acid, m. 217° (tri-Me ester, m. 91°); there is also formed a small amt. of  $\alpha$ -keto- $\beta$ -(2,4-dicarboxyphenyl)isovaleric acid, m. 140 5°, then 206°; these 2 correspond to the ionogenetic carboxylic acid and ionogenetic carboxylic acid of Tiemann and Kruger (*Ber.* 26, 2675, 2663(1893); 31, 808(1898)). I gives a sulfonic acid (the Na salt of which crystallizes with 5 mols. H<sub>2</sub>O), in 50% yield with concd. H<sub>2</sub>SO<sub>4</sub> at 90° for 2 hrs.; *Bz* salt, crystals with 3 mols. H<sub>2</sub>O; sulfonol chloride, m. 89°; sulfonamide, m. 157 8°. I and HNO<sub>3</sub> (d. 1.5) contg. P<sub>2</sub>O<sub>5</sub> give 58% of a dinitro deriv. (II), pale yellow, m. 103; catalytic reduction gives nitroaminonone, m. 171 (HCl salt, decomp. 235 9). *Ac* deriv. m. 158°. Oxidation of I with CrO in concd. H<sub>2</sub>SO<sub>4</sub>-AcOH gives 70% of  $\alpha$ -dinitroionone (III), pale yellow, m. 157 (oxime, m. 188.5°), refluxing III in Ac<sub>2</sub>O with a little H<sub>2</sub>SO<sub>4</sub> gives the  $\beta$  isomer, pale yellow, m. 99°; soln. in concd. H<sub>2</sub>SO<sub>4</sub> and pptn. with H<sub>2</sub>O gives III. Oxidation of II by refluxing the AcOH-H<sub>2</sub>SO<sub>4</sub> mixt. while Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is added, gives  $\alpha$ -(2-carboxydinitrophenyl)isovaleric acid (IV), crystals with 1 mol. H<sub>2</sub>O, yellow, m. 150° and then at 177°, above its m. p., it loses CO<sub>2</sub>, giving  $\beta$ -dinitrophenylisovaleric acid, m. 166.5 8.5°. Oxidation of IV with KMnO<sub>4</sub> in H<sub>2</sub>SO<sub>4</sub> gives 54% of  $\alpha$ -(2-carboxydinitrophenyl)isobutyric acid, m. 170.5°; soly. 13 parts in 100 parts H<sub>2</sub>O at 100°. C. J. West

**Asymmetric syntheses. III. Action of optically active nitrates on  $\alpha$  tetralone.** W. H. Horne and R. L. Shriner. *J. Am. Chem. Soc.* 55, 4652 10(1933), cf. *C. A.* 27, 1330. Treatment of  $\alpha$  tetralone with *p*- and *l*-2-octyl nitrates in the presence of EtOK produces optically inactive salts of  $\beta$ -nitro- $\alpha$ -tetralone, m. 6.2°. C. J. West

**Polycyclic aromatic hydrocarbons. XI. Acetylation of 1,2-benzanthracene.** J. W. Cook and C. I. Hewitt. *J. Chem. Soc.* 1933, 1108 10, cf. *C. A.* 26, 4045. 1,2-Benzanthracene (I) (1 mol.) added to AlCl<sub>3</sub> in PhNO<sub>2</sub>, cooled in ice and kept at 0° for 4 hrs., gives 0.5 g. *p*-*Ac* deriv., pale yellow, m. 117°; *picrate*, orange red, m. 192°; *quinone*, orange, m. 196 7° and 0.3 g. *7-Ac* deriv. (II), pale straw, m. 151 2°; *picrate*, orange, m. 117 8°; *quinone*, orange, m. 219°. If the I was added so that the temp. did not rise above 0° there resulted 12.5 g. of the *picrate*, brick-red, m. 153.5 4.5°, of the *p*- or *10-Ac* deriv. (III), m. 104 5°, oxidation gives 1,2-benzanthraquinone; there also resulted 7 g. of II and a small amt. of a *picrate*, reddish brown, m. 187.5 8°. If the reaction mixt. is cooled in ice during the addn. and kept at room temp. for 4 hrs., there results as the chief product II; some 6-*Ac* deriv., pale yellow, m. 192.5 3.5°, also is formed (*quinone*, golden yellow, m. 197 9°). At 40° III is isomerized to II. The orientation of the 6- and 7-*Ac* derivs. was shown by the oxidation of their quinones to anthraquinone-1,2,6- and 1,2,7-tricarboxylic acids, resp. II and MeMgI give 7 (1,2-benzanthranthyl)dimethylcarbinol, m. 135°; dehydrogenation with concd. HCl in AcOH gives the dimer of  $\alpha$ -isopropenyl-1,2-benzanthracene, m. 218 51°. The poor yields of the *Ac* derivs. preclude their utilization for the synthesis of higher homologs of I. C. J. West

**Preparation of 1,2- and 2,3-diaminoanthraquinones.** P. H. Groggins and H. P. Newton. *Ind. Eng. Chem.* 25, 1030 3(1933).—Crit. studies show that 3',4'-dichloro-2-benzoylbenzoic acid (I) could be obtained in 80% yields by reaction 0.5 mol. phthalic anhydride, 1.1 mol. AlCl<sub>3</sub>, and 3 mol. *o*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> at 90° for 8 hrs. with continuous stirring. I heated at 135° for 7.5 hrs. with 8 parts H<sub>2</sub>SO<sub>4</sub> gave 13% 1,2- and 87% 2,3-dichloroanthraquinone. The isomers could be sep'd. by differences in solv. in EtOH and concd. H<sub>2</sub>SO<sub>4</sub>. Ammonolysis of the pure dihalogen compds. with KClO<sub>4</sub>, CuO or Cu<sub>2</sub>O and NH<sub>4</sub>NO<sub>3</sub> at 200° completely removed the halogen. E. W. Scott

**Occurrence of anthraquinone dyes in the mineral kingdom (graebeite).** Alfred Treibs and Hermann Steinmetz. *Ann.* 506, 171 95(1933). Working with 14 mg. material extd. from a stone found in Ölsnitz numerous spectrographic data are given in an attempt to identify the dye which may be extd. with CHCl<sub>3</sub>; the only definite information found was that it probably is an anthraquinone dye; sublimation appears to give 2 products, termed graebeite a and b; the former analyzes for C<sub>18</sub>H<sub>8</sub>O<sub>4</sub> or C<sub>17</sub>H<sub>6</sub>O<sub>4</sub>. Spectrographic data are given for 1,2,4,5,8-penta-, 1,2,4,5,6,8-, 1,2,4,5,7,8- and 1,2,3,5,6,7-hexahydroxyanthraquinones. C. J. West

**Derivatives of phenanthrene.** Yu. S. Zalkind. *Aukhno-krasochyna Prom.* 2, 5 6, 7 10(1932). Poor yields were obtained in all steps leading to diazo compds. of phenanthrene (I). I was nitrated by introducing it into concd. HNO<sub>3</sub>, the mixt. of isomeric nitro compds. was reduced with H<sub>2</sub>S and aq. NH<sub>3</sub> in 95% alc., the mixt. of NH<sub>2</sub> compds. was diazotized and coupled with 1,4-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> O H, producing a dye which gave red dyeings on wool and silk. The work is being continued. C. B.

**Colored hydrocarbons. A blue hydrocarbon and several colorless hydrocarbons similar to it.** M. Badoche. *Ann. chim.* 20, 200 81(1933); cf. *C. A.* 26, 3250. A description of the hydrocarbons derived from the action of Na upon dehydronobrene, a di-Ph deriv. of dihydrodiphenylenenaphthacene, C<sub>22</sub>H<sub>20</sub>. Spectrophotometric detns. on dehydronobrene and several of its derived hydrocarbons are included. A bibliographic review on the addn. of alkali metals to the unsat'd. hydrocarbons is given.

W. J. Peterson  
**Stereochemistry of bicyclic ring systems. IX. Derivatives of cyclopentanocycloheptane.** Walter Huckel and Ludwig Schmitzspahn. *Ann.* 505, 274 82(1933); cf. *C. A.* 27, 3469.—Cyclopentanocycloheptanone (I or II), b<sub>p</sub> 123°, m. below 18°, d<sub>4</sub><sup>20</sup> 1.0364, n<sub>D</sub><sup>20</sup> 1.52814; *semicarbazone*, m. 195 200°; *oxime*, m. 151° (*Bz* deriv., m. 118°). Catalytic reduction of I gives *cis*-(III) and *trans*-cyclopentanocycloheptanone (IV), b<sub>p</sub> 235°; this is sep'd. through the oximes; III *oxime*, m. 119°; IV *oxime*, m. 140° (*Bz* deriv., m. 88 9°). Na and EtOH give the amines. *cis*-Cyclopentanocycloheptanamine gives 2 *Bz* derivs., m. 191° and 154°, and 2 *Ac* derivs., m. 161° and 151°. The *trans*-amine (V) b<sub>p</sub> 97°; *Bz* deriv., m. 173 1°; *Ac* deriv., m. 114 5°; HNO<sub>3</sub> gives an alc., whose *acid phthalate* m. 132 3°. V (18 g.) yields 20 g. of a quaternary iodide, m. 192°, which yields with Ag<sub>2</sub>O 8 g. cyclopentanocycloheptene (VI), b<sub>p</sub> 63.5°, d<sub>4</sub><sup>20</sup> 0.8996, n<sub>D</sub><sup>20</sup> 1.48711. With OsO<sub>4</sub> VI gives a *keto*ne, whose *semicarbazone* m. 183°. KMnO<sub>4</sub> gives  $\alpha$ -hydromednone

C. J. West  
**New compounds of the furan nucleus.** Al. Mirosescu and G. Ioanid. *Bul. soc. chim. Romania* 15, 40 52(1933). In the reaction between aromatic aldehydes, diketones, and NH<sub>3</sub> one of 3 types of compds. may be formed: an oxazole (I), an imidazole (II), or an open-branched-chain compd. (III). The authors investigated the reaction between C<sub>6</sub>H<sub>5</sub>OCOCOC<sub>6</sub>H<sub>5</sub>, NH<sub>3</sub>, and the following

aldehydes:  $\text{BzH}_2$ , anisaldehyde, furfural and piperonal. In each case a compd. of either type I or III was formed.

W. A. Moore

**Putrefaction of hydroxyproline** Werner Keil and Adolf Gintlya. *Z. physiol. Chem.* 221, 10-12 (1933) A culture medium contg. l-hydroxyproline, glucose, peptone and inorg. salts was inoculated with putril pancreas and incubated 12 days, with frequent neutralization of the acid formed. The bases were then pptd. with phosphotungstic acid and liberated by  $\text{Ba}(\text{OH})_2$ . Aside from a 10% recovery of unaltered hydroxyproline the only substance identified was  $\delta$ -aminovaleric acid which was isolated as the  $\alpha$ - $\text{C}_{10}\text{H}_7\text{NC}$  deriv. Since neither proline nor  $\text{H}_2\text{NCH}_2\text{CH}(\text{OH})(\text{CH}_2)_3\text{CO}_2\text{H}$  could be identified as an intermediate product it is not known whether the opening of the pyrrolidine ring occurs before or after reduction of the OH.

A. W. Dox

**Vegetable fish and insect poisons. VI. Relation of toxicarol to rotenone.** A. Butenandt and G. Hilgtag. *Ann.* 506, 158-74 (1933); cf. *C. A.* 26, 3796. The introduction discusses the tautomeric forms of rotenone (I) and the structure of toxicarol (II). Oxidation of I with  $\text{H}_2\text{O}_2$  in  $\text{EtOH}$ -KOH gives a small yield of toxicaric acid (III). Isorotenone gives an isoxime, m. 194°, which is optically inactive. Reduction of  $\beta$ -dihydrorotenone with Zn and KOH in  $\text{EtOH}$  gives  $\beta$ -dihydrorotenol, m. 110°, which gives a red brown color with  $\text{FeCl}_3$ . II (1 g.) in 40 cc.  $\text{Ac}_2\text{O}$  and 0.75 g.  $\text{AcONa}$ , refluxed 20 min., gives a monoacetate (IV), m. 182.5°, heating with  $\text{Ac}_2\text{O}$  for 2 days gives the diacetate (V). Oxidation of IV with 1 m.  $\text{EtOH}$  gives monoacetyldehydrotoxicarol, m. 235.6°. Dihydrotoxicarol (VI) and  $\text{H}_2\text{O}_2$  give III. VI and I give monomethoxydihydrotoxicarol, yellow, reduced by Zn and  $\text{AcOH}$  to dihydrodehydrotoxicarol (VII), m. 260°, acetate, m. 108.10°, decomps. 250°. V or the diacetate of VI, heated with 1 m.  $\text{EtOH}$  for 2 hrs., is recovered unchanged (85% yield). The hydrate of VI analyzes for  $\text{C}_{20}\text{H}_{20}\text{O}_8$  or  $\text{C}_{21}\text{H}_{20}\text{O}_8$ ; the acetate, m. 192; the benzate, m. 174°; warmed with  $\text{EtOH}$ - $\text{H}_2\text{SO}_4$ , it gives VII.

C. J. West

**New derivatives of 3,3-dimethylindolinones.** II Karl Brunner, et al. *Monatsh.* 62, 373-404 (1931), cf. *C. A.* 26, 724. 3,3-Dimethylindolinone (I) and concd.  $\text{H}_2\text{SO}_4$ , warmed 4-5 hrs., on a boiling water bath, give 97.6% of 3,3-dimethyl-2-thioindolinone-5-sulfonic acid (II), crystals with 2 mols.  $\text{H}_2\text{O}$ , m. 245.7°, purified through the *Ba* salt, crystals with 4 mols.  $\text{H}_2\text{O}$ , the *Ca* salt is anhyd. and the *Na* salt seps. with 2 mols.  $\text{H}_2\text{O}$ . The *Na* salt and  $\text{PCl}_5$ , warmed 0.75 hr. at 130.5°, give the chloride of II, m. 197°; the amide, m. 254.5°. Reduction of the chloride with Sn and  $\text{HCl}$  gives 81.2% of the 5-mercaptan, m. 156.7°, which gives with  $\text{ClCH}_2\text{CO}_2\text{H}$  in alkali the 5-thioglycolic acid (III), m. 193.1° (cor.) (*Na* salt). The 5-position for the  $\text{SO}_3\text{H}$  group is established by the synthesis of III from 5-amino-3,3-dimethylindolinone through the diazo reaction. (With Maria von Mikosch) I in concd.  $\text{H}_2\text{SO}_4$  contg. 30.2%  $\text{SO}_3$  forms a disulfonic acid (IV), crystg. with 1 mol.  $\text{H}_2\text{O}$ , the *Ba* salt seps. with 4 mols.  $\text{H}_2\text{O}$ , the *Na* salt with 3 mols.  $\text{H}_2\text{O}$ , while the *K* salt is anhyd.  $\text{Br}-\text{H}_2\text{O}$  gives the 5,7-Br deriv. and fuming  $\text{HNO}_3$  gives the 5,7-di-NO deriv.  $\text{Na}-\text{Hg}$  appears to split off only 1  $\text{SO}_3\text{H}$  group; 9%  $\text{NH}_4\text{OH}$  at 120° causes no decompos. (With Joseph Riedl.) 1 Methyl-3,3-dimethyl-2-indolinone gives a sulfonic acid, decomps. about 220°, seps. with 2 mols.  $\text{H}_2\text{O}$ ; the *Ba* salt seps. with 4 mols.  $\text{H}_2\text{O}$ , the *K* salt with 1.5 mols.  $\text{H}_2\text{O}$ , the *Na* salt with 0.5 mol.  $\text{H}_2\text{O}$ ; the acid and  $\text{Br}-\text{H}_2\text{O}$  give a di-Br deriv., m. 131°, fuming  $\text{HNO}_3$  also splits off  $\text{H}_2\text{SO}_4$ . 3,3,7-trimethylindolinone (V) also gives a sulfonic acid, whose *Ba* salt is anhyd. and whose *Na* salt seps. with 4.5 mols.  $\text{H}_2\text{O}$ . I and  $\text{P}_2\text{S}_5$  in  $\text{C}_6\text{H}_5\text{MgCl}$  give (92%) of 3,3-dimethyl-2-thioindolinone (VI), m. 108-9°;  $\text{HgCl}_2$  gives the compd.  $\text{C}_{10}\text{H}_{10}\text{NSHgCl}$ , m. 227.8°; the *Ag* salt is egg-yellow and with  $\text{MeI}$  gives the *Me* ether, m. 65°; VI gives a methiodide, m. 165°, which gives the *Me* ether with  $\text{Na}_2\text{CO}_3$ . VI and  $\text{ClCH}_2\text{CO}_2\text{H}$  give the thioglycolic acid, pale yellow, m. 151°. VI and  $\text{Ac}_2\text{O}$  give the *Ac* deriv., m. 39-40°; *Bz* deriv., m. 80°.

V gives a 2-thio deriv. (VII), m. 153-4°; the 2-thioglycolic acid m. 90°. VII is oxidized to a disulfide, m. 127.8°. 3,3,5-Trimethyl-2-thioindolinone, m. 167°; *Ag* salt, yellow; the thioglycolic acid, pale yellow, m. 136°; the disulfide m. 165°. 3,3,6-Trimethylthioindolinone, m. 135-6°.

C. J. West

**New synthesis for alkyl- and aryl-substituted coumarans.** Joseph B. Niederl and Edward A. Storch. *J. Am. Chem. Soc.* 55, 4549-55 (1933); cf. *C. A.* 27, 968. The condensation was carried out by refluxing for 5 hrs. molar quantities of the alc. and phenol in  $\text{AcOH}-\text{H}_2\text{SO}_4$  and distg. the polymer at atm. pressure.  $\text{CH}_3\text{CH}_2\text{OH}$  and  $\text{PhOH}$  give *o*-isopropenylphenol and 2-methylcoumaran, b. 208.12°,  $d^{25}_D$  1.028,  $n^{25}_D$  1.5302; *p*- $\text{MeC}_6\text{H}_4\text{OH}$  gives 4-methyl-2-isopropenylphenol and 2,4-dimethylcoumaran; *m*- $\text{MeC}_6\text{H}_4\text{OH}$  gives the 5-Me and 2,5-di-Me isomers, resp.; *o*- $\text{MeC}_6\text{H}_4\text{OH}$  gives 6-methyl-2-isopropenylphenol (penta-Br deriv., m. 190.1°) and 2,6-dimethylcoumaran, b. 253.8°,  $d^{25}_D$  0.993,  $n^{25}_D$  1.5289.  $\text{PhCH}_2\text{CH}_2\text{OH}$  and  $\text{PhOH}$  give 3-phenyl-2-(2-hydroxyphenyl)-1-propene, b. 193.6°,  $d^{25}_D$  0.953,  $n^{25}_D$  1.5027, and 2-benzylcoumaran, b. 308.11°,  $d$  1.061,  $n$  1.5760. *p*- $\text{MeC}_6\text{H}_4\text{OH}$  gives 3-phenyl-2-(2-hydroxy-5-methylphenyl)-1-propene, b. 208.12°,  $d^{25}_D$  1.000,  $n^{25}_D$  1.5314, and 2-benzyl-4-methylcoumaran, b. 320.5°, m. 198.9°,  $d^{25}_D$  1.017,  $n^{25}_D$  1.5778 (Br gives 2,3,5,6-tetrabromo-*p*-cresol); this differs from 1,4-dimethyl-2-phenylcoumaran, b. 310.4°,  $d^{25}_D$  1.080,  $n^{25}_D$  1.561, which was prepd. for comparison and which yields a penta-Br deriv., m. 249°. *m*- $\text{MeC}_6\text{H}_4\text{OH}$  gives 3-phenyl-2-(2-hydroxy-4-methylphenyl)-1-propene, b. 207.11°,  $d^{25}_D$  1.033,  $n^{25}_D$  1.5290, and 2-benzyl-5-methylcoumaran, b. 322.7°,  $d^{25}_D$  1.080,  $n^{25}_D$  1.5836. *o*- $\text{MeC}_6\text{H}_4\text{OH}$  gives 3-phenyl-2-(2-hydroxy-3-methylphenyl)-1-propene, b. 212.16°,  $d^{25}_D$  0.993,  $n^{25}_D$  1.5352, and 2-benzyl-6-methylcoumaran, b. 318.22°,  $d^{25}_D$  1.017,  $n^{25}_D$  1.5860. The coumarans form 50-65% of the reaction products. A reaction mechanism is discussed.

C. J. West

**Hydrolysis and reduction of hydantoinoxindoles** Harry R. Henze and Charles M. Blau. *J. Am. Chem. Soc.* 55, 4621-5 (1933). —The action of  $\text{Ba}(\text{OH})_2$  on the condensation products of hydantoin with isatin (hydantoin- $\beta'$ -oxindole) and 5-methylisatin (the 5-Me deriv., reddish brown, m. above 310° (I)) completely destroyed the hydantoin nucleus and reduced the isatin to the corresponding oxindole. Hydantoin-5,3-oxindole and its 5-Me homolog (II), m. 306.7°, differ toward  $\text{Ba}(\text{OH})_2$  in that the former gives 2-quinolin-1- $\alpha$ -boxylic acid and the latter 5-methylloxindole. While II is smoothly formed from I with  $\text{HI}$  in  $\text{AcOH}$ , reduction with  $\text{HI}$  and red P gives 2-keto-6-methyl-1,2,3,4-tetrahydroquinolin-4-carboxylic acid.

C. J. West

**Action of chlorine upon the 3-carbethoxy-4-hydroxy-1-nitrophenylpyrazoles.** F. D. Chattaway and D. R. Ashworth. *J. Chem. Soc.* 1933, 1389-93. —3-Carbethoxy-4-hydroxy-1-*p*-nitrophenylpyrazole and  $\text{Cl}$  in  $\text{CHCl}_3$  give 3,5-dichloro-3-carbethoxy-1-*p*-nitrophenyl-4-pyrazolone (I), orange, m. 131°; 1-(2'-chloro-4'-nitrophenyl) deriv., pale yellow, m. 87°; 1-*o*-nitrophenyl deriv., deep yellow, m. 98°; *m*- $\text{NO}_2$  isomer, yellow, m. 135°. I and  $\text{HI}$  (K1 in  $\text{AcOH}$ ) liberate I and give 5-chloro-3-carbethoxy-4-hydroxy-1-*p*-nitrophenylpyrazole, m. 146° (*Ac* deriv., m. 121.5°); 1-(2'-chloro-4'-nitrophenyl) deriv., m. 191°; 1-*o*-nitrophenyl deriv., m. 142°, *m*-isomer, m. 109°. The pyrazole ring in I readily opens when I is boiled with  $\text{EtOH}$  or dissolved in cold dil. alkali, giving *Et* diketosuccinate *p*-nitrophenylhydrazone (II), pale yellow, m. 125°; I and  $\text{MeOH}$  give the 1-Et 2-Me deriv., deep yellow, m. 138°;  $\text{PhOH}$  the 1-Et 2-Pr deriv., pale yellow, m. 92°;  $\text{PhCH}_2\text{OH}$ , the 1-Et 2-benzyl deriv., pale yellow, m. 147°. 1-Ethyl 2-methyl diketosuccinate 1-(2'-chloro-4'-nitrophenylhydrazone), yellow, m. 115°; the 2'-Br deriv., yellow, m. 126°; *Et* diketosuccinate *m*-nitrophenylhydrazone, yellow, m. 84°; 1-ethyl 2-methyl diketosuccinate 1-*o*-nitrophenylhydrazone, yellow, m. 116°; *m*- $\text{NO}_2$  isomer, pale yellow, m. 105°. 3-Carbethoxy-4-hydroxy-1-(2',6'-dichloro-4'-nitrophenyl)pyrazole and  $\text{Cl}$  in  $\text{CHCl}_3$  give the 5-Cl deriv., m. 200°. II and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$  in  $\text{EtOH}$  give *Et* diketosuccinate *p*-nitrophenyl-

osazone, yellow, m. 180°; heating with  $C_6H_5N$  gives *Et 4,5-diketo-1-(4'-nitrophenyl)pyrazolone-3-carboxylate 1-(4'-nitrophenylhydrazonate)*, deep yellow, m. 257° (decompn.); other methods of prepn. are given. II and  $NH_4OH.HCl$  in EtOH give *Et diketosuccinate oximino-p-nitrophenylhydrazonate*, pale yellow, m. 163° (decompn.); AcONa in AcOH gives *3-carbethoxy-4-ketoisooxazolone 4-p-nitrophenylhydrazonate*, yellow, m. 186° (decompn.); this also results from II,  $NH_4OH$  and AcONa in AcOH at 100°. II, Br and AcONa in AcOH give *Et chromoglyoxylate p-nitrophenylhydrazonate*; Cl gives the corresponding  $\alpha$ -Cl deriv. I and dil. NaOH (2 g. NaOH in 500 cc.  $H_2O$ ) give *Et 2-II diketosuccinate p-nitrophenylhydrazonate* (III), yellow, m. 141°; the Et H or di-Et ester, boiled 0.7 hr. with 10 cc. EtOH and 20 cc. concd. HCl, gives *diketosuccinic anhydride p-nitrophenylhydrazonate*, orange, m. 243° (decompn.). III and  $Ac_2O$ , heated to boiling, give *3-carbethoxy-4,5-diketo-1-p-nitrophenylpyrazolone hydrate*, m. 95-105°;  $H_2O$  is lost after 1 week over  $P_2O_5$ ; the hydrate and  $NH_4OH.HCl$  in AcOH give *1-oximino-3-carbethoxy-1-p-nitrophenyl-5-pyrazolone*, yellow, decomp. above 222°.

C. J. West

**Alkylation of pyrazolones.** Adolf Sonn and Wolfgang Litten. *Ber.* 66B, 1582-8(1933).—In a series of ketonol compds. smooth C-alkylation was obtained only with easily dissolved alkyl halides (C. A. 27, 961). Similar phenomena have been encountered with ketimide-enamine tautomers of the phenyl-5-pyrazolone series. The loosely bound allyl and benzyl residues can be introduced into the 4 position of antipyrine (I) but the 4-derivs. could not be detected in the greatly resmified reaction products obtained by heating I with EtI and its homologs. From the oil obtained by heating I and EtI at 130-40° was isolated a small amt. of a cryst. substance m. 256°, perhaps identical with the product formed by condensation of 2 mols. 1-phenyl-3-methylpyrazolone (Mohr, *Ber.* 38, 2578(1905)). "1-ech. pyrazolone" (II) and  $PrBr$  at 130-5° gave only the *N-Pr* deriv. (1-phenyl-2-propyl-2-methylpyrazolone), light yellow, b.p. 220-40°, m. 90-1°, gives with  $FeCl_3$  a red, with nitrite a yellow, with  $K_2Cr_2O_7.H_2SO_4$  a yellow green color changed to green by a drop of water; *pyrate*, m. 155-8°. I reacts with  $PrBr$  only at 190° in sealed tubes; besides unchanged I, only II could be detected. Hexyl bromide reacts with II or I only at 200°; from the resin was isolated in unsatd. hydrocarbon which, from its b. p. (66-8°), was undoubtedly  $\alpha$ -hexene. On the other hand, II and I with allyl bromide at 120° gave 1-phenyl-3-methyl-4,4-diallylpyrazolone; I also gave a very small amt. of a substance, m. 79-81°, giving with  $K_2Cr_2O_7.H_2SO_4$  a green-blue color destroyed by diln. with water and which may therefore have been the 4-allyl compd., none of the 2,1-diallyl deriv. was detected. I boiled or heated in a tube at 180° with twice the calcd. amt. of  $PhCH_2Cl$  yielded a dibenzylpyrazolone, m. 139-40° (III), and (in the tube at 180°) some of the 4-benzyl deriv. II reacted in the same way in a tube at 180°, but if the mixt. was heated directly to boiling, there was formed, with much evolution of HCl, an isomeric etherol. *dibenzylpyrazolone*, m. 91° (IV). Both isomers were obtained from the 4-benzyl compd. with  $PhCH_2Cl$  and NaOH on the water bath (cf. Auwers and Dersch, C. A. 22, 3182, who obtained only III). The 2,4-deriv., m. 152°, was not observed in any of these benzylations. IV is thought to be the 4,4-compd., for with Na and  $AmCl$  it gives the 4-benzylpyrazolone and a small amt. of a product giving with  $FeCl_3$  the color reaction characteristic of hydroxypyrazolones, whereas the reactions of III with  $FeCl_3$  and  $C(NO_2)_4$  and its behavior toward Br point to the 4-benzyl-5-benzoyloxy-pyrazole structure. 1-Phenyl-2-benzyl-3,4-dimethyl-5-pyrazolone, from the dimethylpyrazolone and  $PhCH_2Cl$  (1:2.5 at the b. p. or 1:1 at 120°), m. 128.5-30°, is insol. in NaOH and easily sol. in concd. HCl and does not react with nitrite. 1-Phenyl-2-benzyl-5-methyl-3-pyrazolone, from the methylpyrazolone and  $PhCH_2Cl$  (1:1 at 120° or 1:2 at 180°), m. 103-4°; *pyrate*, m. 106-9°; HCl salt, m. 155-8°. 1-Phenyl-2-benzyl-5-pyrazolone, from the pyrazolone and

$PhCH_2Cl$  (1:1) at 120°, m. 125-6°, sol. in concd. but not in dil. HCl, gives a blood-red color with  $FeCl_3$ . 1-Phenyl-2-benzyl-3-methylpyrazolone (7.9 g.) with  $MeCl$  (1:3) at 150° gives 2.4 g. unchanged pyrazolone, 0.1 g. II, 1.9 g. I; with  $MeCl$  (1:1.5) at 180°, a resmified oil from which is isolated 0.5 g. 1-phenyl-3-methyl-4-benzylpyrazolone.

C. A. R.

**Acid chloride, ester and acid anilide of imidazole-4,5-dicarboxylic acid and their methyl and phenyl homologs.** Y. Tamamushi. *J. Pharm. Soc. Japan* 53, 580-92 (1933); cf. C. A. 23, 1639.—In order to learn the properties of imidazole-4,5-dicarboxylic acid (I), its acid chloride, ester and acid anilide were prepd. Heating of 2-methylimidazole-4,5-dicarboxylic acid (II) with  $PCl_5$  and  $POCl_3$  gave 2-methylimidazole-4,5-dicarboxylic acid 5-chloride (III), plates, m. above 300°, insol. in  $CHCl_3$ , EtOH and  $Et_2O$ . Esterification of II with HCl and EtOH gave the di-Et ester, needles, m. 88°, sol. in  $H_2O$ , EtOH and  $CHCl_3$ . HCl salt of II, m. 187°, sol. in  $H_2O$ , EtOH,  $CHCl_3$ , insol. in  $Et_2O$ . 2-Phenylimidazole-4,5-dicarboxylic acid gave the di-Et ester, needles, sol. in EtOH, difficultly sol. in  $H_2O$  and  $Et_2O$ . The anhyd. ester m. 190°, while the crystals with 1 mol.  $H_2O$  m. 120°. I or II and  $PhNH_2$  gave the corresponding monoanilides, but III and  $PhNH_2$  gave the unexpected dianilide (IV), m. 298°, sol. in  $H_2O$ , EtOH and  $Et_2O$ . It is explained that the  $CO_2H$  group at position 5 of the imidazoledicarboxylic acids cannot form anilide in free condition, but when it is in the form of  $-COCl$ , it easily gives the anilide. Nao Uyei

**Bis-3,3'-benzothiazolylene 1,2-dihydride.** R. Stollé and M. Merkle. *J. prakt. Chem.* 138, 221-4(1933).—The action of  $HNO_3$  upon 10 g. 3-amino-1,2-benzothiazole gives 3.7 g. of bis-3,3'-benzothiazolylene 1,2-dihydride (I), m. 104°; Ag salt. Fuming  $HNO_3$  oxidizes I to  $o$ - $HO_2SC_6H_4CO_2H$ ; red fuming  $HNO_3$  gives a compd., possibly  $(o$ - $HO_2SC_6H_4CO_2H)_2$ , whose  $NH_4$  salt m. 238°.

C. J. West

**Molecular rearrangement of some  $o$ -acyloxyacetophenones and the mechanism of the production of 3-acylchromones.** Wilson Baker. *J. Chem. Soc.* 1933, 1381-9. In an attempt to prep. its  $PhCH_2Cl$  ether, 4- $o$ -benzoylresacetophenone (I), m. 106-7° (Ac deriv., pale cream, m. 82-3°), was heated with 1 mol.  $PhCH_2Cl$  and  $K_2CO_3$ ; the product (20% yield) was  $\omega,1$ -dibenzoylresacetophenone (2-hydroxy-4-benzoyloxydibenzoylmethane) (II), yellow, m. 167°. It is evident that the  $PhCH_2Cl$  had taken no essential part in the formation of II and this is confirmed by its prepn. from I and also from resacetophenone (III) by the action of 1 and 2 mols. of  $BzCl$ , resp., in  $C_6H_6$  in the presence of  $K_2CO_3$  (yields, about 20%); 3 mols.  $BzCl$  and I reacted slowly and the yield was only 8%. The dibenzoate of III, m. 80-1°, heated with  $C_6H_6$  or  $PhMe$  and  $K_2CO_3$ , undergoes intramol. rearrangement, giving II. The migration concerns solely the  $o$ - $BzO$  group, since it occurs neither in I nor in  $p$ - $BzOC_6H_4Ac$  and further, if 2 different aryl radicals esterify the HO groups of III, only the 1 in the  $o$ -position migrates. 2- $O$ -Benzoyl-4- $O$ -acetylresacetophenone, from the  $O$ -Ac deriv. and  $BzCl$ , m. 67°, likewise rearranges in  $PhMe$  to II. Boiling II with AcOH and AcONa for 6 hrs. gives 7-hydroxyflavone; soln. of II in concd.  $H_2SO_4$  gives the same product; heating II with AcOH and a little concd. HCl gives 7-benzoyloxyflavone, m. 157-8°. The dianilide (IV) of III m. 118°; I and anisoyl chloride in  $C_6H_5N$  give 4- $O$ -benzoyl-2- $O$ -anisoylresacetophenone (V), m. 109-10°. Heating III and anisoyl chloride with  $K_2CO_3$  for 20 hrs. gives 7.9 g. of  $\omega,1$ -dianisoylresacetophenone (VI), yellow, m. 170-1°, and 20 g. 4- $O$ -anisoylresacetophenone, m. 151°, best prepd. by shaking an aq. alk. soln. of III with 1 mol. of anisoyl chloride. VI also results by rearrangement of IV or V. VI, AcOH and AcONa give 7-hydroxy-1'-methoxyflavone (*pratol*), m. 263-4°; the Ac deriv., m. 176-7°, is dimorphic (needles and plates). The diveratrate of III, m. 151-2°, gives  $\omega,1$ -diveratroylacetophenone, yellow, m. 159-60°; AcOH and AcONa give 7-hydroxy-3',4'-dimethoxyflavone, m. 265°. Gallacetophenone tribenzoate, m. 118-9°, with  $K_2CO_3$  in  $PhMe$  gives  $\omega,1,4$ -tribenzoylgallacetophenone, yellow, m.

1934, AcOH and AcONa give 7,8-dihydroxyflavone **III**, PhCH<sub>2</sub>CH<sub>2</sub>COCl and PhMe, heated for 8 hrs., give a mixt. of 1-*o*-methoxy-2-acetophenone, yellow, m 131°, and 1-cinnamoyloxy-2-acetylchromone, m 216.7°. 2-Hydroxy-4-benzoyloxyphenyl ketone m 121.2°. Br<sub>2</sub>/C, K<sub>2</sub>CO<sub>3</sub>, and PhMe give 7-hydroxy-2,3-diphenylchromone, m 190.1°, and 2-hydroxy-1-benzoyloxyphenyl benzyl ketone **III** or **II**, Br<sub>2</sub>O and Br<sub>2</sub>ONa, heated 8 hrs. at 20°, give 1-benzoyloxy-2-benzoylphenyl, pale yellow, m 167°. 2,4-AcMeC<sub>6</sub>H<sub>3</sub>OH, EtCOEt and Na give 2-propionylacetyl-4-methylphenol (**VII**), m 75.6°. AcOH and HCl give 6-methyl-2-ethylchromone, m 51. 2-Acetoacetyl-4-methylphenol (**VIII**), m 94.6°, gives 2,6-dimethylchromone, m 10°. **VII**, AcO and AcONa or **VIII**, (EtCO)<sub>2</sub> and EtCOONa give propionyl-2,6-dimethylchromone, m 82. The production of *o*-hydroxydibenzoylmethane by oxidation furnishes an explanation of the formation of the 3-acetylated chromones which are sometimes isolated when *o*-hydroxyacetophenone is heated with the anhydride and the Na salt of a carboxylic acid. The mechanism of the formation of chromone and 3-acetylated chromones is discussed. C. J. West.

**Pyrenium salts XXI. Bifluorenyl oxide.** W. D. H. and W. Hoskins, *J. prakt. Chem.* **138**, 115-58 (1933). Cf. C. A. **27**, 4498. Hydroxyflavonium perchlorate **I**, AcONa and AcO, refluxed 0.5 hr., give 10% of 1,1,1-trifluorene, 3-oxide **II** red, m 232.60 (decompn.) dissolves in dark green, soln. are bleached by sunlight. **II** is obtained in EtOH from **I** with AcONa if the EtOH soln. is heated only 0.5 hr., there results is the principal product, 4-hydroxy-4,4-bifluorene, yellow, m 192.5, crystal with 0.5 mol C<sub>2</sub>H<sub>5</sub>, warming in AcOH gives **II**. The mother liquor of **II** contains 1,1-bifluorenyl oxide **III** and **IV** (decompn.), 1,1-bifluorenyl oxide, from 3,4-dihydroxydibenzoylmethane m 134°, solid dark red, m 238.5, the 7,1-difluorene, dark red, m 226.34 (44%), the 3,1-difluorene, red, m 233.10 (10%), the 7,1-trifluorene, dark red, m 260. C. J. W.

**Decomposition of wogonin with caustic alkali.** formation of isretol. Shunzo Hattori and Kozo Hayashi, *J. Chem. Soc. Japan* **54**, 919-21 (1933). Cf. C. A. **27**, 3431. Heating of 1 g wogonin **I** with 17 g 50% KOH gives 0.5 g isretol (**II**) and 0.2 g PhCOH. Formation of **II** from **I** gives another proof that the structure of **I** is 3,6-dihydroxy-8-methoxyflavone. K. Katsuta.

**β-polyene oxide.** A. Sign and H. Schmid, *J. Pharm. Soc. Japan* **53**, 341-9 (1933). Heating 1 g Me(HO)C<sub>6</sub>H<sub>4</sub> with ZnCl<sub>2</sub> at 2.0-80° gave a compd C<sub>12</sub>H<sub>10</sub>O (I), colorless, m 61, difficultly sol. in H<sub>2</sub>O, sol. in org. solvents. Heating of (o-HOC<sub>6</sub>H<sub>4</sub>)<sub>2</sub> with ZnCl<sub>2</sub> gave biphenylene oxide. Therefore **I** seems to be biphenylene oxide (**II**). But according to the literature, **II** crystallizes in small platelets in 160°, difficultly sol. in Et<sub>2</sub>O. Oxidation of **I** in CrO<sub>3</sub>-AcOH under 50° gave a monobenzene acid (**III**), needles, m above 270°, difficultly sol. in H<sub>2</sub>O, sol. in org. solvents. **III** and CH<sub>3</sub>N gave the di Me ester (**IV**), colorless, m 105°. Oxidation of **IV** gave a dibenzene acid (**V**), needles, m above 270°, difficultly sol. in H<sub>2</sub>O and org. solvents. **V** and CH<sub>3</sub>N gave the di Me ester (**VI**). The tri of **III** in sealed tube at 300° for 4 hrs. gave needle, m 41, which is probably Me ester and Frueger's methylbiphenylene oxide, but on account of the small yield, no further work made. The same operation on **V** gave biphenylene oxide (**VI**), needles, m 81, from the result, it is concluded that **I** is 3,6-dimethylbiphenylene oxide (or β-polyene oxide), **III**, 3-methyl-5-carboxybiphenylene oxide, and **V**, 3,6-dicarboxybiphenylene oxide. Nao Uyei.

**Cannabis indica resin IV. Synthesis of some 2,2-dimethylidibenzopyrans and confirmation of the structure of cannabidiol.** R. S. Cahn, *J. Chem. Soc.* **1933**, 1400-5. Cf. C. A. **26**, 4019. It has been suggested that cannabidiol (I) is a 2-hydroxy-2,5-trimethyl-2,5-methylidibenzopyran. The present work brought no further evidence of structure, synthesis of 2,2-dimethylidibenzopyran and a few simple deriv. was undertaken. *o*-Bromophenyl *o*-bromobenzoate, b.p. 246.7°, m 306, does not react

1 with Mg and only slightly with Cu powder in C<sub>6</sub>H<sub>5</sub>Me<sub>2</sub> at 150°, at 285-305° for 6 hrs. liquids b.p. 200-250° and 260° resulted which did not solidify. Ph anthranilate through the diazo reaction did not give the lactone of *o*-HOC<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>CO<sub>2</sub>H-*o* it results in 2,2', yield from *o*-HOC<sub>6</sub>H<sub>4</sub>N<sub>2</sub>H<sub>5</sub>O<sub>2</sub> (**II**) and PhOH, with MeMgI there results almost quant. 2-hydroxy-2'-hydroxyisopropylbiphenyl, m 147.50, dehydrated to 2,2-dimethylidibenzopyran, b.p. 186.1° (90% yield), by P<sub>2</sub>O<sub>5</sub> in C<sub>6</sub>H<sub>5</sub>Me<sub>2</sub>, 2 ring closure was only partly effected by distg. at 30 min., on by heating at 175° for 45 min. **II** (40 g) and *p*-Me-C<sub>6</sub>H<sub>4</sub>OH (100 g) give 10.1 g of the lactone of 2-hydroxy-2-methylbiphenyl-2-carboxylic acid, m 144.5, MeMgI gives nearly quant. 2-hydroxy-2-methyl-2'-hydroxyisopropylbiphenyl, m 112. 2-*tert*-butyl-2'-hydroxyisopropylbiphenyl, m 127, dehydration of the phenol gives 2,2', 2,2'-trimethylidibenzopyran (**III**), b.p. 201°, m 78. AcO on the water bath gave the same product. **II** and PhOMe give a small yield of the lactone of 2-hydroxy-2-methylbiphenyl-2-carboxylic acid, m 167, MeMgI gives 2-hydroxy-2-methyl-2'-hydroxyisopropylbiphenyl, m 132.1 (118% after drying), P<sub>2</sub>O<sub>5</sub> gives 2-methoxy-2,2-dimethylidibenzopyran, a pale yellow resin. **III** heated 8 hrs. at 200° with a mixt. of 1 part AcOH and 3 parts concd. HCl acid with HCl at 0°, give 2-hydroxy-2-methylbiphenyl m 110.11. Me ether, m 90. *Bz* deriv., m 109.10. HNO<sub>3</sub> gives a compd, m 199-200, which is not the expected nitrobenzoic acid. Application of this acid first to **I** gives a phenol C<sub>12</sub>H<sub>10</sub>O, b.p. 255, m 61.2. It gives only NO<sub>2</sub> deriv., oxidized by hot HNO<sub>3</sub> to 6-nitro-*m*-toluic acid. Although this work does not afford any evidence as to the positions of the substituent in the ring, it is held that, taken in conjunction with the experimental previously reported it proves the structure of **I** in all except the particular. While **I** may be formed from a phenylene oxide during the process of isolation, it is believed that it is not such in the crude resin. C. J. W.

**Piperidine derivatives XIII. Phenyl and phenyl alkyl substituted piperidinopropyl benzoates.** I. A. Walters and S. M. McElvain, *J. Am. Chem. Soc.* **55**, 462, 9 (1933). Cf. C. A. **27**, 149. 2-(*γ*-Phenylpropyl)piperidine, b.p. 132°, d<sub>4</sub><sup>20</sup> 1.0171, n<sub>D</sub><sup>20</sup> 1.511, 20% yield. 2-(*o*-Phenylbutyl) deriv., b.p. 143°, d<sub>4</sub><sup>20</sup> 1.0010, n<sub>D</sub><sup>20</sup> 1.5142. PhCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OPh and NaNH give 2-(*o*-phenyl-*o*-phenylbutyl)cyanide, pale yellow, b.p. 180.5°, d<sub>4</sub><sup>20</sup> 1.0816, n<sub>D</sub><sup>20</sup> 1.5004. Catalytic reduction gave *p*-phenyl-*o*-phenylamylamine, whose HCl salt m 124.8, refluxing the amine with HBr and refluxing the free Br amine in PhMe gives *o*-phenylpiperidine, b.p. 275.5°, d<sub>4</sub><sup>20</sup> 1.0010, n<sub>D</sub><sup>20</sup> 1.5140, 2-(*γ*-phenylpropyl) deriv., b.p. 161.5°, d<sub>4</sub><sup>20</sup> 1.0121, n<sub>D</sub><sup>20</sup> 1.5180. 2-(*o*-phenylbutyl) deriv., b.p. 164.6°, d<sub>4</sub><sup>20</sup> 1.0152, 3-benzyl deriv., b.p. 279.5°, 1-Ph deriv., b.p. 255.8°, the HCl salts of the 1st 3 compds m 194.1, 129.1° and 146.7°, resp. The following piperidinopropylbenzoate HCl salts were prepd. 2-Ph (**I**), m 186.7°, 2-(*γ*-phenylpropyl) (**II**), m 103.5°, 2-(*o*-phenylbutyl) (**III**), m 179.81°, 2-Ph (**IV**), m 180.1°, 3-benzyl (**V**), m 163.1°, 1-Ph (**VI**), m 174.5°. The following figures give the duration of corneal anesthesia in min. and the intravenous toxicity to white rat, M.L.D. in mg/kg: **I**, 15, 26; **II**, 45, 50; **III**, 7, 28; **IV**, 20, 12; **V**, 31; **VI**, 26, 26. It is apparent that the extremely long duration of anesthesia is a fact only with those substances which contain a PhCH<sub>2</sub> or PhCH<sub>2</sub>CH<sub>2</sub> substituent in the 2 position of the piperidine nucleus. Increasing the length of the C chain which seps the Ph group from the N atom to more than 3 C atoms or decreasing it to 1 C atom diminishes very considerably the anesthetic activity of the resulting compds. C. J. West.

**Synthesis of quinoline derivatives.** II. K. Drzewonski, J. Moszcz, G. Dorthenowa and W. Ryzewski, *Roczniki Chem.* **12**, 925-35 (1933). Cf. C. A. **27**, 3937. The *o*-toluid of PhCOMe heated with PhNCS yields 4-anilino-2-phenyl-8-methylquinoline, m 171° (HCl salt, m 191°, *purate*, m 260.1°, NO deriv., m 194°), which on fusion with KOH gives 1-hydroxy-2-phenyl-8-methylquinoline,

(II), m 87–8°, crystals with 1 mol.  $\text{CHCl}_3$ ,  $[\alpha]_D^{25} -45.3^\circ$  (EtOH, c 4.490), from MeOH it seps with 1 mol solvent, m 92.3°,  $[\alpha]_D^{25} -66.7^\circ$  (EtOH, c 2.134), the *HCl salt* seps with 1 mol AcOEt, m 162° and then decomps, 220°, the *HCl salt* seps with 1 mol  $\text{H}_2\text{O}$ , the *methiodide* m 225°, the *di-Ac deriv* m 140°,  $\text{NH}_4\text{OH HCl}$  gives the *mono-Ac deriv*, m 150°. A small amt of dihydrometathetabainone is formed. The so-called *p*-dihydrothetabainone of Kondo is a mixt of II and dihydrometathetabainone (III), the existence of a diastereoisomer of III, which could serve as proof of the Schöpf I formula, has not yet been demonstrated. Catalytic reduction of III gives *dihydrometathetabainol*, m 120°, whose *HCl salt* has  $[\alpha]_D^{25} 16.4^\circ$  (EtOH, c 4.128). I, reduced with  $\text{N}_2\text{H}_4\text{H}_2\text{O}$  and EtONa at 140° for 3 hrs, gives *dihydrodesoxytelacodermine*, b<sub>100</sub> 130.5°, m 72°,  $[\alpha]_D^{25} 9.8^\circ$  (EtOH, c 1.109), III gives *tetrahydrodesoxytelacodermine*, amorphous, whose *HCl salt* has  $[\alpha]_D^{25} 12.5^\circ$  (EtOH, c 1.925). Dehydration of II gives an anhydrometathetabainol of uncertain structure, b<sub>100</sub> 130°, m 106°,  $[\alpha]_D^{25} 20.1^\circ$  (EtOH, c 1.813), *Ac deriv*, m 166°, catalytic reduction gives the *dihydro deriv*, b<sub>100</sub> 130° (C. J. West).

**Specific configurative esterification of secondary alcohols in the presence of brucine or strychnine.** Richard W. Gler *Ann* 506, 718 (1933), cf C. A. 26, 592. The behavior of a series of 16 alcohols with AcO in the presence of brucine and with AcO and  $\text{Bz}_2\text{O}$  in the presence of strychnine is reported. The rotations are given for the acetate or benzoate and for the alk which is not esterified. With the acetate (with brucine) all rotations are (–) except for *N*-But HOH and the unesterified alk has a (–) rotation. All the benzoates are (–) but the unesterified alk vary in rotation. With strychnine all the benzoates are (–) with the exception of *M*-Et HOH (C. J. West).

**Alkaloids of jaborandi leaves. III. Synthesis of pilocarpine and pilocarpidine.** N. A. Probozhenskii, V. I. Vamp, V. A. Probozhenskii and M. N. Shchukin *Izv* 66B, 1336 (1933), cf C. A. 27, 28. The isopropyl acid is heated some hrs at 50–60° with  $\text{SOCl}_2$  allowed to stand overnight, again heated over 1 hr heated from excess of  $\text{SOCl}_2$  in *vacuo* repeatedly washed with dry benzene and the resulting light yellow viscous thick oil treated in ether at 15° with  $\text{CH}_3\text{N}$ . The dark oil with only *dia ketone* is decomposed in ether at 15° with  $\text{HCl}$  gas, giving *chloromethyl d* homopilocypyl ketone (I, yield) m 80.7°,  $[\alpha]_D^{25} 11.3^\circ$  (in  $\text{CHCl}_3$ ) the with  $\text{C}_6\text{H}_5\text{CO}_2\text{N}_3$  in abs alk on the water bath gives 50% of the *phthalimidomethyl ketone*, m 157°,  $[\alpha]_D^{25} 11.1^\circ$  (in  $\text{CHCl}_3$ ), which is hydrolyzed with 10% aq  $\text{HCl}$  to the *amino ketone HCl salt* (I) and the I is converted with aq  $\text{KSCN}$  on the water bath into *m* (recept) 40% of *homopilocypylmido-ole* (pilocarpine thiol) (42.01% yield, based on the phthalimidomethyl deriv), m 207.85° (decompn),  $[\alpha]_D^{25} 122.96^\circ$  (MeOH). With  $\text{HCl}$  in boiling water the thiol gives pilocarpine (II) identical with the natural product and methylated by  $\text{MeI}$  to pilocarpine, which was isolated as the nitrate, 10% yield, based on the thiol, m 175.65°,  $[\alpha]_D^{25} 15.64^\circ$  (EtOH). In some expts the intermediate I and II were isolated. I (44.3% yield, based on the phthalimidomethyl deriv), m 179.81°,  $[\alpha]_D^{25} 90.00^\circ$  (EtOH). II (32.17% yield, based on the thiol), m 132.5–3.1° (evolution),  $[\alpha]_D^{25} 71.78^\circ$  (H<sub>2</sub>O). IV **Diazomethyl isopilocypyl ketone and its transformations.** N. A. Probozhenskii and M. J. Kalachnik *Ibid* 1511.5. From *di* isopilocypyl chloride in ether slowly added to 2.5 mol  $\text{CH}_3\text{N}_2$  in ether at –10° is obtained in good yield the *dia ketone*,  $\text{CH}_2\text{N}_2\text{COCH}_2\text{CH}_2\text{CHCOCHN}$  (I), giving

pours I from solns, especially in the light. *Dibromo-methyl ketone* (20% yield), m 76.5–7.5°. *Aceto-di-homopilocypylalcohol* (I, with  $\text{CH}_3\text{OH}$  instead of  $\text{CH}_3\text{N}_2$ ), from the *diazo ketone* with aq mineral acids, does not crystallize and decomps on distn in *vacuo*, it does not react with  $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$  at low temps and only in part at 110° (in xylene), giving the *p*-nitrobenzoate, m 129.5–30°, also obtained from the chloromethyl ketone with  $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{Na}$  in abs alk on the water bath. *Benzooate*, obtained in the same 2 ways is the  $\text{NO}_2$  deriv, m 71.5–2° (C. A. R.).

**Strychnos alkaloids. XIII. Degradation experiments with isonitrosostrychnine.** Heinrich Wieland and Konrad Kaziro *Ann* 506, 607 (1933), cf C. A. 27, 1331. Reduction of isonitrosostrychnine (I) (C. A. 26, 3508) with  $\text{SnCl}_4$  in concd  $\text{HCl}$  gives the *di HCl salt* (II), does not m 230°, of *L*-aminostrychnine, m 88.6°. Reduction with  $\text{Zn}$ ,  $\text{ZnCl}_2$  and  $\text{HCl}$  gives the *ZnCl salt* of II, decomps 305–12°. II with  $\text{NaN}_3$  and dil  $\text{HCl}$  gives 60–70% of *12* duxostychnine (III), decomps 107–6° (2nd precipn decomps at 129–30° and 1rd, 149–90°). III and  $\text{H}_2\text{SO}_4$  give *L*-hydroxystrychnine, m 205°, catalytically reduced to the *dihydro deriv* (IV), m 282–4°. The *Br deriv* of IV m 290–2°. IV is oxidized by  $\text{KMnO}_4$  in  $\text{Me}_2\text{CO}$ - $\text{AcOH}$  to a *dicarboxylic acid*  $\text{C}_8\text{H}_{10}\text{O}_6\text{N}_2$ , decomps 290°. Isonitrosostrychnine is reduced by  $\text{ZnCl}_2$  and  $\text{HCl}$  to the *amino deriv*, analyzed as  $\text{C}_8\text{H}_{10}\text{O}_6\text{N}_2 \cdot 2\text{HCl} / \text{ZnCl}_2$ , which does not decomps below 300°. The *ZnCl salt* of the nitrosoamine is reduced by  $\text{Zn}$  and  $\text{HCl}$  to isonitrosodihydrobrucinecarboxylic acid, analyzed as  $\text{C}_8\text{H}_{10}\text{O}_6\text{N}_2 \cdot 2\text{HCl} / \text{ZnCl}_2$ . *L*-Dihydrobrucine, yellow, decomps 100–1°. The *HCl salt* of I and  $\text{SOCl}_2$ , with cooling, give 50–70% of the pale yellow *HCl salt*, decomps above 300°, of the *carbamate acid* (V), m 210–3° (decompn), and one of the base (VI) in 2.8–9 and crystals with 1 mol MeOH. V and  $\text{EtOH}$  give the *aldehyde base* (VII), m 217° (crystals with 1 mol  $\text{CHCl}_3$ , m 1–5°), *HCl salt*, decomps 310°. *Methiodide*, does not decomps 300°. *di Ac deriv*, does not decomps 300°. *oxime*, decomps 206–7°. *oxime*, decomps 21°. I and  $\text{SOCl}_2$  give V and the *urea* (VIII), decomps 210–6° (*HCl salt* decomps 270–2°). VIII and 2  $\text{N}$   $\text{NaOH}$  give *norstrychninecarboxylic acid* (IX), m 290–6°. I and  $\text{Me}_2\text{C}_6\text{H}_4\text{SO}_2\text{Cl}$  and  $\text{C}_6\text{H}_5\text{N}$  give the *compd*

$\text{C}_8\text{H}_{10}\text{O}_6\text{N}_2\text{S}$ , decomps above 290°. XIV **Vomicidine.** Heinrich Wieland, Friedrich Holscher and Pratulla K. Bose *Ibid* 507, 69–82. Vomicidine (I) in  $\text{C}_6\text{H}_5\text{N}$  gives an *Ac deriv*, m 229–30° (decompn). Electrolytic reduction of dihydrovomicidine or catalytic reduction of I gives *dihydrovomicidine* (II), decomps 296–8°, crystals with 0.5 mol  $\text{H}_2\text{O}$ ,  $[\alpha]_D^{25} 34.57^\circ$  (for acid sulfate). I,  $\text{MeI}$ , MeOH and 2  $\text{N}$   $\text{NaOH}$ , refluxed 8 hrs, give the *Me ether* (III), pale bluish green, m 205°, this also results with  $\text{Me}_2\text{SO}$  and  $\text{NaOH}$ , both expts were in  $\text{N}$ . I and  $\text{MeI}$  in abs EtOH, refluxed 1 hr, give the *methiodide* of III, m above 300°, this also results from III and  $\text{MeI}$  at 100°. Heating I and  $\text{MeI}$  in EtOH at 100° for 2 hrs gives the *dimethiodide* (IV), gradually darkens

If the reactions of aliphatic diazo compds, cold mineral acids easily decomps it with evolution of  $\text{N}_2$ , I reacts with it so vigorously that in the absence of a solvent a part of the I sublims, but in ether there is obtained I (based on the isopilocypyl acid used as starting material) of the *diisodimethyl ketone*, light yellow, decomps 10–12°, unstable in the dark in the solid form but de-

above 250°, crystals with 2 mols. H<sub>2</sub>O. IV, shaken with AgCl and then catalytically reduced, gives the dimethochloride of II. IV and excess CH<sub>3</sub>N in MeOH give the phenolbaine of I, C<sub>11</sub>H<sub>13</sub>O<sub>2</sub>N, m 140 and then 200°, with HCl it yields the HI salt of the methiodide of I, which also splits off MeCl with CH<sub>3</sub>N. If the HI salt in H<sub>2</sub>O is neutralized with Na<sub>2</sub>CO<sub>3</sub> and the MeOH ext. treated with H<sub>2</sub>, the methiodide of III results. II forms a dimethiodide, m 230 (decomps). CH<sub>3</sub>N gives a phenolbaine, does not m 300°. Oxidation of I with CrO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub> gives an acid, C<sub>11</sub>H<sub>11</sub>O<sub>3</sub>N, m 242 (decomps). I in 0.5 N HCl gives with 6% CrO<sub>3</sub> (isomeric), analyzed as the HCl salt, C<sub>11</sub>H<sub>11</sub>O<sub>3</sub>N<sub>2</sub>HCl, pale yellow, which shows no m p. XV. Desoxyvomincine and isonitroso vomincine. H. Wieland and Georg Vavogli. *Ibid.* 82 (9). Electrolytic reduction of desoxyvomincine (I) gives desoxyvomincine, C<sub>11</sub>H<sub>11</sub>O<sub>2</sub>N, which has not been crystallized. There also results a base C<sub>11</sub>H<sub>11</sub>O<sub>2</sub>N, m 161, catalytic reduction of which gives C<sub>11</sub>H<sub>11</sub>O<sub>2</sub>N (II), m 18, [α]<sub>D</sub><sup>20</sup> (CHCl<sub>3</sub>). Catalytic reduction of I (PbO) gives a mixt. of II the base C<sub>11</sub>H<sub>11</sub>O<sub>2</sub>N, m 211, and the base C<sub>11</sub>H<sub>11</sub>O<sub>2</sub>N, m 220, the yield of II is about 40% of the other 2 bases 10%. Vomincine gives an isonitroso derm (III), yellow, has no m p. the Beckmann rearrangement with SOCl<sub>2</sub> gives a carbamic acid lactone (IV) C<sub>11</sub>H<sub>11</sub>O<sub>2</sub>N, m 218, hydrolysis with NaOH gives a *ner vomincine acid* blacken above 320° the *Me ester* of the *O Me derm* m 194. Catalytic reduction of IV gives a *dihydro compd* m 208. Reduction of III with Zn and HCl gives the ZnCl<sub>2</sub> salt of aminovomincine from which was prepd *iso vomincine*, yellow, darkens at 200°, it resembles chazoy trychnin. C. J. West.

The successive disintegration of  $\alpha$ -isocinchonine (cinchoniline) up to the toxic derivatives. Julius Dubi, Adam Konopnicki and Jerzy Suszko. *Ac. milit. Chem.* 13, 44-72 (1934). Hydrolysis of the enol ether to the hydroxydihydro compd is the mechanism of the present disintegration.  $\alpha$ -Isocinchonine (I) is obtained by heating anhyd  $\alpha$ -isocinchonine acid sulfate (m ab) EtOH and EtO) *in vacuo* to 140° for several hrs. The product purified with III and crystal from dil EtOH on ligron (70-80), m 98-100.  $\alpha$ -Hydroxydihydro cinchonine (II) obtained most readily by heating on dil water bath I with 20 cc 50% HCl in CO<sub>2</sub> 1.5 hr. after alkalinizing and extracting with EtO in EtO crystal from EtOAc at m 124-126.  $\alpha$ -Isocinchonine (III) is stable to strong acid undergoing no change, contrary to former report disintegrates in place on heating with dil acid. A low decomposition temperature arising from III is sensitive to dil acid especially the strong ones. The following derivatives I were prepd: N Ac, N nitroso, bromo N Me, III N Me methiodide bromo N methyl of II brom N Me (IV) N Me methiodide  $\beta$ -nitrophenylhydrazon (V) of IV and perate of V of III the monoxide of III.

C. I. Ichmowski.

Resanols. I.  $\beta$ -Amyrin of *Manilla elemi*. I. & Spring. *J. Chem. Soc.* 1933, 1345.  $\alpha$  and  $\beta$ -Amyrin may be separated by fractional soln. of their insates in CHCl<sub>3</sub>.  $\beta$ -Amyrin acetate is oxidized by H<sub>2</sub>O in AcOH to the acetate m 201.2, of  $\alpha$ - $\beta$ -amyrin, m 201.2, this is a solid oxide since it does not give a color with C(NO) in CHCl<sub>3</sub> and does not absorb Br<sub>2</sub>. In attempting to isomerize  $\beta$ -amyrin could HCO<sub>2</sub>H give the formate m 258. Partial isomerization was achieved by treating the alc. in glycerol AcOH with HCl at 5° for 6 hrs, the product being a mixt. of the acetate and the *isoacetate* m 246. Reduction of  $\beta$ -amyrin with Na and AmOH gives  $\beta$ -myrin m 95, catalytic reduction (Pd black) gives *iso  $\beta$ -amyrene* m 82. C. J. West.

Presence of syringoside (syringin) in the bark of *Phyllaea latifolia* L. and *P. decora* L. A. Krinner. *Bull. soc. chim. Ind.* 15 (64) 50 (1934). *ibid.* 1-27 (934) 1934. Syringoside was isolated from the fresh bark and its formula established a phicol (syringol) phicolide 2,6,4,1 C<sub>11</sub>H<sub>11</sub>(OMe)(CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH)OCH<sub>2</sub>CH<sub>2</sub>O. The prepn and properties of syringoside and phicol are described. I. L. Calton.

The action of heat on resinic acids. M. Fanica. *Bull. inst. chim.* 1933, 151-65, 181-9. Ultimate isomerization of the acids of gum turpentine is as follows: primary (sapinic) acids  $\rightarrow$  sapinabatic  $\rightarrow$  abietic  $\rightarrow$  pyroabietic. By heating Aleppo pine resin in CO<sub>2</sub> for about 100 hrs. at 240  $\pm$  2° or 27° in an electrically heated glass flask, there was obtained a 35-40% yield of *d*- or  $\alpha$ -pyroabietic acid (I), m 172.3°,  $\alpha$ <sub>D</sub><sup>20</sup> 60°,  $\alpha$ <sub>D</sub><sup>25</sup> 68°, consequently isomerization to I was more complete than that obtained by Dupont and Duboué (C. I. 22, 1839). I gives no nitrosocarbonate, nitrosite or Br deriv. Sulfonation by low 0° with 60% Br<sub>2</sub> H<sub>2</sub>SO<sub>4</sub> in yield about 25%, C<sub>19</sub>H<sub>19</sub>O<sub>3</sub>S, m 213.1°, very slightly sol in EtO, insol in CHCl<sub>3</sub> and CCl<sub>4</sub> sol in alc. (from which it can be crystd only by evapn of the solvent), very sol in hot H<sub>2</sub>O, from which it is completely pptd by mineral acids, gives both a di Na and a mono Na salt. Attempts to obtain higher sulfonated deriv. caused considerable decomps and yielded no definite products. I is monobasic, the Na and K salts, prepd in an anhyd solvent, and the NH<sub>4</sub> salt, prepd by passing dry NH<sub>3</sub> through a C<sub>19</sub>H<sub>19</sub>O<sub>3</sub> soln of I, are gelatinous and inactive. The Na, Co, Cu<sup>2+</sup>, Mn<sup>2+</sup>, Fe<sup>3+</sup> and Ba salts prepd by double decomps of the Na salt in presence of EtO and glycerol (to prevent hydrolysis) are very sol in EtO, very sol in CH<sub>3</sub> (Ba salt only slightly), lightly sol in alc, slightly sol in MeCO (Cu salt very sol), and insol in H<sub>2</sub>O. Dehydration of I by action of S by I. M. in Chung's method (C. I. 23, 117) yields 15% of *retene* from the acid and a discussion of the results of Ruzicki and co-workers. I concludes that the structural formula of abietic acid is

By heating of Bordeaux pine resin in m glass at 240° for 100 hrs., followed by distn and repeated fractional crystaln of the solid fraction, there was obtained m 7 or 8% pyroabietic acid (II) m 185.7°, [α]<sub>D</sub><sup>20</sup> 5°, isomorphous with I, probably the same as obtained by Fournier and Gratch (C. I. 23, 520). Heating of  $\alpha$ -pinic acid gave no II. Heating of  $\beta$ -pinic acid gave an I acid which is probably identical with II but which could not be definitely identified as such. It is probably in very intimate mixt. with  $\alpha$ -pinic acid. Heating of alpine acid gave no II. Heating of abietic acid prepd from Bordeaux pine resin gave a mixt. of approx 50% I and 50% of II, m 185.90°, [α]<sub>D</sub><sup>20</sup> 52°, [α]<sub>D</sub><sup>25</sup> 65.4°, fusion of a mixt. of this II and of  $\alpha$ -pinic acid, calcd to have [α]<sub>D</sub><sup>20</sup> -25°, gave crystal m 160.5 and having the same characteristic as those obtained by heating of  $\beta$ -pinic acid. Heating of Aleppo pine resin in Al (instead of m glass) gave an I acid, which is possibly identical with II.

A. Papineau Couture.

Proteins. X. Silk fibroin (2). The action of hypobromite on silk. Stefan Goldschmidt, Karl Martin and Werner Heidinger. *Ann.* 505 25-61 (1933). (C. I. 24, 140). Different kinds of silk behave similarly to wool and K<sub>2</sub>OBr, the only exception being Tuscan silk, which consumes much less K<sub>2</sub>OBr than does Chinese, Japanese or Malay silks. The degradation products contain glycol and alamine in the ratio 1.1% to 1.75%, only in expts in which the reaction time is 8 min or less are other NH<sub>2</sub> acid present (2.4%). XI. Silk fibroin (3). The action of hydrochloric acid on silk. S. Goldschmidt, Gertrud Frey and Kessy Strauss. *Ibid.* 262-73. The action of 5 N HCl upon silk fibroin at 25° dissolves 60% in 80 hrs and only 15% addn in 200 hrs. The hydrolysis of the insol residue (I) gives alanine, glycine, tyrosine in the mol ratio of 13.8:1. I is also de-

oxidized to II; with HCl the soln. of IV becomes browned and then green. In the MeOH-KOH degradation of pheophytin there results many times, in place of I, the pseudo compd. (V); I and V in Et<sub>2</sub>O can be sepd. by extg. V with a buffer of  $pH$  6.8-7.0. The ester of V m. 276° (cor.). V is stable and gives II with HCl-AcOH. In the fractionation of I, there is isolated *alloporphyrin*, acid no. 10, whose *Me ester* m. 269° (cor.); it is unstable and gives with C<sub>6</sub>H<sub>5</sub>N II; after 3 months it appears to give chloroporphyrin *c<sub>6</sub>*. XXXVII Chlorophyll *b*. II. Proof of the isocyclic ring in chlorophyll *b*. H. Fischer, Albert Hendschel and Ludwig Nussler. *Ibid.* 83-106.—Pheophorbide *b* (I) with CH<sub>3</sub>N<sub>2</sub> in MeOH (N atm.) gives 50% of rhodim *g* tri-Me ester (II) and a *chlorin ester* (III), extd. with 7% HCl, m. 191°, which contains 3 MeO groups; hydrolysis with 22% HCl gives a *chlorin*, C<sub>36</sub>H<sub>38</sub>N<sub>4</sub>O<sub>6</sub> (IV), m. 209°, with 1 MeO group; alk. sapon. appears to give the same compd. Degradation of IV with glycol gives a product resembling chloroporphyrin *c<sub>4</sub>*. The mesoreinol melt of IV gives a product resembling chloroporphyrin *c<sub>6</sub>*. I and CH<sub>3</sub>N<sub>2</sub> in EtOH (N atm.) give 70% II. I with HI gives pheoporphyrin *b<sub>6</sub>* (V), with CH<sub>3</sub>N<sub>2</sub> (MeOH, N atm.) it yields a porphyrin resembling pheoporphyrin *a<sub>6</sub>* (VI) but which m. 273°, depressing the m. p. of VI and analyzing for a compd. between C<sub>36</sub>H<sub>38</sub>N<sub>4</sub>O<sub>6</sub> and C<sub>36</sub>H<sub>36</sub>N<sub>4</sub>O<sub>6</sub>. If the action of CH<sub>3</sub>N<sub>2</sub> is continued for 5 days there results a product resembling chloroporphyrin *c<sub>6</sub>* (VII), m. 237°. III and HI give a compd. whose *Me ester*, C<sub>36</sub>H<sub>36</sub>N<sub>4</sub>O<sub>6</sub>, m. 249°, which resembles VII but depresses its m. p. The oxime (VIII) of V, for which a new method of prep. is given, forms a *Me ester*, m. 229°; the same compd. results from the ester of V. VIII, sapon. by 22% HCl, gives a mixt. of products; the principal compd., extd. by 15% HCl, m. 248°. The oxime of pheoporphyrin *b<sub>6</sub>* ester, m. 230°. The hydroxynitile of I, reduced with HI (4 mm. at 45°), gives the same compd. as the methanolysis of V. V and MeOH-KOH or HI-AcOH give *rhodimporphyrin g tri-Me ester*, C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub> (IX), m. 265°, also obtained from rhodim *g* tri-Me ester with HI and PH<sub>3</sub> in AcOH. V gives a di-Me ester, m. 277°. The oxime of IX m. 277°. IX and C<sub>6</sub>H<sub>5</sub>N-Na<sub>2</sub>CO<sub>3</sub> give V. Sapon. of X gives free rhodim *g*, which was not decarboxylated by C<sub>6</sub>H<sub>5</sub>N on heating 1 hr. or on heating in a tube at 135°. XXXVIII. Splitting of chlorophyll *a* and its derivatives by diazo methane. Crystalline allomerized ethylpheophorbide *a*. II. Fischer and Josef Riedmair. *Ibid.* 107-23. Pheophorbide *a* (I) (2 g.) in 2 l. MeOH contg. a little C<sub>6</sub>H<sub>5</sub>N, treated with 8 g. CH<sub>3</sub>N<sub>2</sub> and allowed to stand several days, gives 520 mg. chlorin *c* tri-Me ester (II), 300 mg. of a product nearly identical with dimethylpheopurpurin 7 and 100 mg. dimethylpurpurin, also 50 mg. of a chlorin with an acid no. greater than 16. The yield of II decreased markedly with a decrease in the quantity of MeOH used but appears to be independent of the concn. of CH<sub>3</sub>N<sub>2</sub>. Recrystd. methylpheophorbide *a* (III) (500 mg.) in 25 cc. C<sub>6</sub>H<sub>5</sub>N and 1 l. MeOH with 2.5 g. CH<sub>3</sub>N<sub>2</sub> (N atm.), allowed to stand 24 hrs., gives about 80% of II, a methylpyropheophorbide which yields a phylloerythrin ester with HI, and a chlorin which yields a complex porphyrin mixt. with HI. "Native" I or III with MeOH-CH<sub>3</sub>N<sub>2</sub> in N gives II quant. Allomerized ethylchlorophyllide *a* + *b* (IV) or I does not give II. Native I in PrOH treated with MeMgI decompd. by PrOH and the product degraded by HI gives pheoporphyrin *a<sub>6</sub>* and a trace of phylloerythrin. Methylchlorophyllide *a*, allomerized with quinone in abs. EtOH (N atm.) gives with HI pheoporphyrin *a<sub>6</sub>*. IV (2 g.), allomerized with quinone, gives 0.95 g. 10-ethoxyethylpheophorbide *a*, C<sub>40</sub>H<sub>44</sub>O<sub>6</sub>N<sub>4</sub>, does not m. 280°; HI gives pheoporphyrin *a<sub>6</sub>*. The behavior of various chlorophyll derivs. in EtOH, PrOH and C<sub>6</sub>H<sub>5</sub>N toward O<sub>2</sub> is reported. Methylchlorophyllide *a* + *b* in EtOH absorbs 0.87-1.08 mols. O<sub>2</sub> in 11-18 hrs.; in C<sub>6</sub>H<sub>5</sub>N only a trace of O<sub>2</sub> is absorbed in 120 hrs.; in EtOH with 15% C<sub>6</sub>H<sub>5</sub>N, 1.11 mols. in 24 hrs.; in C<sub>6</sub>H<sub>5</sub>N with 3% EtOH, 0.68 mol. in 120 hrs.; in PrOH, 1.10 mols. in 16 hrs.; addn. of pheophorbide *a* (which does not absorb O<sub>2</sub>) decreases the rate of reaction in EtOH so that

1.06 mols. are absorbed only in 192 hrs. Chlorophyll absorbs 0.96 mol. O<sub>2</sub> in 8 hrs. XXXIX. Catalytic hydrogenation in the chlorophyll series. H. Fischer and Eduard Lakatos. *Ibid.* 123-57.—Pyrroporphyrin (I) in AcOH with PtO<sub>2</sub> absorbs 3 mols. H<sub>2</sub>; oxidation of the reduced product with air for 2 days gives 60% of I. Phylloporphyrin (II) in CHCl<sub>3</sub> absorbs 3 mols. H<sub>2</sub> and in CHCl<sub>3</sub>-petrol. ether, 2 mols.; reoxidation gives 40-8% II. Desoxophyllyerythrin (III) in AcOH absorbs 2.94-3.58 mols. H<sub>2</sub> and gives 51% III on oxidation. Synthetic III in AcOH absorbs 5 mols. H<sub>2</sub>; oxidation gives only a little III. Phylloerythrin (IV) in AcOH also absorbs 3 mols. H<sub>2</sub> but on oxidation gives only 12% of IV. Pheophorphyrin *a<sub>6</sub>* (V) in AcOH absorbs 3 mols. H<sub>2</sub> and gives 24% of V on oxidation. Chlorin *c* in AcOH absorbs 3.24 mols. H<sub>2</sub>; oxidation gives a little II and 21% of chloroporphyrin *c<sub>6</sub>* (VI). The tri-Me ester of VI in AcOH-HI absorbs 3.10 mols. H<sub>2</sub> and on oxidation gives 25% of chloroporphyrin *c<sub>6</sub>* (VII). Pheophorbide *a* (VIII) (Sandoz) in AcOH absorbs 3.82 mols. H<sub>2</sub> and on oxidation gives pheoporphyrin *a<sub>6</sub>* (IX), a little II, VII and pheoporphyrin *a<sub>7</sub>*; native VIII also absorbs 3.88 mols. H<sub>2</sub> and gives the same oxidation products; with Pd as catalyst 2.87 mols. H<sub>2</sub> are absorbed and oxidation gives 55% IX. Pseudo-verdoporphyrin di-Me ester in AcOH absorbs 4 mols. H<sub>2</sub> and on oxidation gives 59% of rhodoporphyrin. VIII and 1 mol. H<sub>2</sub> give 56% dihydrophosphoride *a* (X), C<sub>36</sub>H<sub>38</sub>N<sub>4</sub>O<sub>6</sub>·H<sub>2</sub>O, acid no. 14.5; *Me ester*, m. 218° (cor.), acid no. 16.5. X and KOH, heated 6 days, give 62% II; degradation of X with HI gives 38% IX and a little rhodoporphyrin; HBr-AcOH gives II and III. X absorbs 2.16 mols. H<sub>2</sub> with Pd as catalyst and on oxidation gives 68% IX. The oxime of X (48% yield) seps. with 1 mol. H<sub>2</sub>O and decomps. about 236°; with HI it gives 62% of the oxime of IX. X, heated with C<sub>6</sub>H<sub>5</sub>N for 15 hrs., gives 70% of pyrodihydrophosphoride *a*, acid no. 12. *Me ester*, m. 239°, acid no. 14; it absorbs 2.36 mols. H<sub>2</sub>. X and C<sub>6</sub>H<sub>5</sub>N-KOH, heated 40 sec., give 66% of dihydrochlorin *c* (XI), acid no. 3.5, tri-Me ester (XII), m. 181°, acid no. 5.5; it absorbs 2.11 mols. H<sub>2</sub>. X with CH<sub>3</sub>N in MeOH-C<sub>6</sub>H<sub>5</sub>N gives 76% XII (in N) at 70° (in O). XII in C<sub>6</sub>H<sub>5</sub>N and Na<sub>2</sub>CO<sub>3</sub>, heated 40 hrs., gives 13% X. XI in C<sub>6</sub>H<sub>5</sub>N, boiled 15 hrs., gives 74% of pyrodihydrochlorin *c* (dihydrochlorin *c<sub>1</sub>*), acid no. 4; di-Me ester, m. 151°. C. J. West

Sulfo compounds of chlorophyll-porphyrins, a consideration of the atomic structure of porphyrins. Alfred Froehs. *Ann.* 506, 196-259 (1933) —Phylloporphyrin (I) (g.), added in small portions to 25 cc. ice cold 20% oleum and the soln. after 15 min. added to 0.1 l. of ice and H<sub>2</sub>O, gives 0.6 g. phylloporphyrin sulfone (I), C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub>S, small violet prisms or red-brown-violet rods, no definite m. p., acid no. 10; the *Me ester* (II), prepd. with MeOH-HCl, m. 294°; with CH<sub>3</sub>N<sub>2</sub>, m. 320°; by sulfonation of the *Me ester* of phylloporphyrin, m. 302°. The Cu complex of II, C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub>SCu, red, decomps. 250-80°; the Zn and Fe complexes were also prepd. C<sub>6</sub>H<sub>5</sub>N compd. of I, dark brown, loses the C<sub>6</sub>H<sub>5</sub>N quantitatively over P<sub>2</sub>O<sub>5</sub> at 100° in *vacuo*. The di-K salt of I, blue-violet prisms with 2 mols. MeOH; it is very hygroscopic and takes up 4 mols. H<sub>2</sub>O from the air. I (0.3 g.) in 50 cc. concd. HCl give the Cl compd., C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub>SCl; soln. in 0.1 N KOH apparently gives the K salt of I. The *Me ester*, C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub>SCl, black-blue, decomps. 270-90°, giving phyllo- and pyrroporphyrin esters; soln. in concd. H<sub>2</sub>SO<sub>4</sub> gives II; Cu salt of the ester. I with MeOH-KOH at 150-5° gives phylloporphyrin (III) with a little pyrroporphyrin (IV); the ester of I, heated above the m. p., gives a mixt. of these 2 esters. The Cu salt of I is stable toward AcOH at 150° but suffers total decomp. at 200°. III in H<sub>2</sub>SO<sub>4</sub>·H<sub>2</sub>O gives phylloporphyrinsulfonic acid, whose *Me ester* (V), m. 224° (decompn.), yields a red Cu salt. In the attempt to prep. the Fe complex by heating in CHCl<sub>3</sub>, reduction occurs, the compd. being C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub>SiFeCl<sub>2</sub>; at a lower temp. the trd Fe complex, C<sub>37</sub>H<sub>40</sub>O<sub>6</sub>N<sub>4</sub>SiFeCl<sub>2</sub>, is formed. C<sub>6</sub>H<sub>5</sub>N and V give violet needles, m. 228° (decompn.), which lose 9.4% at 100°. Addn. of MeOH to a CHCl<sub>3</sub> soln. of V gives II. The Me

$C_{25}H_{42}O_6$ , m 215.50° (decompn),  $[\alpha]_D^{20}$  40.8° (*penta-Me ester*, m 165.6). This  $\beta$ -acid is rearranged to the  $\alpha$ -acid by HCl or alkali probably by conversion of a  $\gamma$ - into the more stable  $\delta$ -lactone. A. W. Dole.

**Cholesterol** Hamms *Lettre / physiol Chem* 221, 75, 89(1933). Several hydrocarbons were prepd from cholesterol deriv. with a view to elucidating some of the doubtful points of cholesterol structure. Reduction of the emicarbazono of cholesterol by NaOH converted it into *pseudo cholesterol* (I), m 75.9, and small amts of cholesterol and cholestanol. Oxidation of I in AcOH by CrO gave a *keto acid* (II),  $C_{27}H_{46}O_3$  (*semicarbazone*, m 240, decompn), *oxime*, m 165.6, and a *hydrocarbon* (III),  $C_{27}H_{46}$ , m 80°. Oxidation of I in AcOH followed by oxidation with CrO also gave II which on distn *in vacuo* yielded III. Oxidation of III by O<sub>2</sub>, then by CrO, gave a *keto acid*  $C_{27}H_{46}O_3$  m 161,  $[\alpha]_D^{20}$  32. II was oxidized by KOBr to a *tricarboxylic acid* (IV)  $C_{27}H_{46}O_6$ , which in 16% solution is the anhydride and m 200. Distn of IV at 240/60 and 14 mm gave a *hydrocarbon*,  $C_{27}H_{46}$ , m 85.9. The pyro acid of the dicarboxylic acid from cholesterol was reduced in AcOH by H<sub>2</sub>/Zn and HCl to a *hydrocarbon*,  $C_{27}H_{46}$ , m 85.9,  $[\alpha]_D^{20}$  32. The ketone,  $C_{27}H_{46}O$  obtained by catalytic hydrogenation of the pyroketone from the Diels acid was converted into the *semicarbazone*, m 268.70 (decompn), and the latter reduced by NaOH to a *hydrocarbon*,  $C_{27}H_{46}$ , m 85.9,  $[\alpha]_D^{20}$  32. The same hydrocarbon was obtained by Pd hydrogenation of III. These hydrocarbons and their intermediate acid are discussed in the light of known reactions of various cholesterol deriv. A. W. Dole.

**The chemistry of chlorophyll** Kenneth E. Armstrong *Chemistry and Industry* 1933, 809-16. A review of work on the constitution of chlorophyll, together with brief reference to its function in photosynthesis. I. H.

**Structure of the second nucleus of cholesterol** St. Minovici and M. Vanghelovici *Bul. soc. chim. Roumanie* 15, 944(1933). Starting with cholesterol the authors had previously prepd a  $C_{27}$  dicarboxylic acid (I) m 204 (cf *C* 1 24 2467). I, when treated with AcO and diluted yield an anhydride (II) m 100. When II is dissolved in NaOH and HCl added a ppt is obtained, which, recrystd from AcOH, m 204. Mixed mps indicate it to be identical with I. The formation of the anhydride and not the ketone indicates that the carboxyl groups of I are on adjacent C atom, but the ring may be either 5 or 6 membered. Accepting a bicyclic structure to be present in cholesterol and from analogy between I and diphenic acid the authors conclude that the 2nd ring of the compound is 6 membered. W. A. M.

**Conversion of cholesterol into 6 ketoallocholic acid** O. Stamm *Z. physiol Chem* 200, 348(1933). 6-chlorocholestanol, m 147,  $[\alpha]_D^{20}$  4.1, was obtained in 80% yield by treatment of cholesterol with PCl<sub>5</sub> and oxidized by CrO in AcOH to 6-chloroallocholic acid which without isolation was hydrolyzed by NaOH to 6-hydroxyallocholic acid (I), m 210 (*Me ester* m 101). This is the *epi* form of the acid obtained by Wieland and Dine (cf *C* 1 27, 91) from hydoxycholeic acid. Oxidation of I by CrO gave the same 6 ketoallocholic acid m 101, as that obtained by W. and D. from their isomeric acid. This is evidence that ring II of cholesterol is identical with ring III of the bile acids. A. W. Dole.

**The tetracarboxylic acid  $C_{27}H_{46}O_8$  from cholesterol** A. Windaus and M. Duppe *Ber* 66B, 1567-5(1933). Cholesterol had been degraded to a tetracarboxylic acid  $C_{27}H_{46}O_8$  (I) (*ber* 57, 3609(1901)) and later an intermediate ketodicarboxylic acid  $C_{27}H_{46}O_7$  (II) had been obtained from cholesterol ester chloride (cf *A* 15, 3219). Minovici and Vanghelovici apparently without knowing of the early work, also obtained II in the same manner. They formulated it as a  $\beta$ -ketodicarboxylic acid and state that on further oxidation it yields a tricarboxylic acid and the tetracarboxylic acid which is undoubtedly formed is unstable that it cannot be isolated (cf *A* 24 2467). A repetition of the earlier work has failed to confirm the observations of M. and V., their supposed tricarboxylic acid was presumably a mixt. of unchanged

II with I. The 4th carboxyl in I cannot be titrated sharply with alc. KOH and phenolphthalein, I was therefore converted with MeOH and concd. H<sub>2</sub>SO<sub>4</sub> into the *di-Me ester*, m 165.6, which titrates as a dibasic acid (equiv. wt found 255, calcd 262). The *ultra Me ester* was also prepd and purified by distn in a high vacuum, although amorphous, it gave correct anal results. When heated 30 min at 175°, I loses only 1 mol H<sub>2</sub>O and no CO<sub>2</sub>, but after 1 hr at 230° it splits off 1 mol CO and 2 mols H<sub>2</sub>O. The product, however, is not a tricarboxylic acid but the *anhydride*,  $C_{27}H_{46}O_6$ , m 232.2, of a *ketodicarboxylic acid*, m 161.8, readily obtained from the anhydride by alk sapon. In their paper on the action of CrO<sub>3</sub> on cholesterol acetate and chloride, M. and V. (cf *A* 23, 2121) likewise fail to consider earlier work and propose very improbable structures. C. A. R.

**Cholatrienic acid II** Photochemical alteration of cholatrienic acid and of choladienic acid Ziro *Lettre / physiol Chem* 221, 104(1933), cf *C* 1 26, 3402. Ultra violet irradiation of  $\alpha$ -cholatrienic acid I in CHCl<sub>3</sub> for 9 hr changes the sp rotation from -22.63 to +2.4. The product is a non crystalline in which can be hydrogenated by PtO + H<sub>2</sub> to cholanic acid. The resin therefore contain at least 1 acid isomeric with  $\alpha$ -cholatrienic acid III or IV, which is tentatively designated  $\alpha$ -cholatrienic acid II. It differ from the starting material in most of its color reactions. The  $\beta$ -choladienic acid from desoxycholeic acid is not altered by ultra violet rays. Hence it appears that the point of attack by the ultra violet rays is the B ring in cholatrienic acid where a shifting of the double bond occurs. The failure to react with maleic anhydride show that no conjugated double bond are present. A. W. Dole.

**Sterol group XVIII** An attempt to define the position of the hydroxyl group in ergosterol I. M. Heilbron, K. M. Samant and J. C. I. Simpson *J. Chem. Soc.* 1933, 1110-13, cf *C* 1 27, 2433. Oxidation of chloro-ergostane (I) with CrO<sub>3</sub> in AcOH gives a *chloroallonorcholeic acid* (II), m 213.4 (0.1 g from 15 g I). *Me ester*, m 168.9, which recrystd resulted a dicarboxylic acid,  $C_{27}H_{46}O_6$ , m 219.21 (*Me ester*, m 81), probably identical with the dicarboxylic acid from ergostanol. The mp of an authentic specimen of  $\beta$ -chloroallonorcholeic acid m 218 (and its *Me ester*, m 170), was strongly depressed by II and its *Me ester*, that the 2 acids are isomeric ( $C_{27}H_{46}O_6$ ) is shown by the fact that reduction of their esters with Na and PrOH give the same allonorcholeic acid, m 170.70. These facts indicate that either a cis trans isomeric change has occurred during the chlorination of I or the other of the sterols or that the HO group in ergosterol is attached to a different C atom from that in cholesterol, the latter is believed the more probable. C. J. West.

**Constitution of stigmasterol** I. Fernholz, *Ann* 507, 128-38(1933). Stigmasterol acetate (I) gives a *di-bromide*, m 122.5, O<sub>2</sub> gives Pt(iso Pr)CHClO, the 1st mol Br thus enters the nucleus and not the side chain. I (6 g) in 100 cc CHCl<sub>3</sub>, treated with 2 g Br in CHCl<sub>3</sub> with cooling and then with O<sub>2</sub> during 6 hrs, give the *1-derivative* (II), m 235 (decompn) (*Me ester* (III), m 155.9,  $[\alpha]_D^{20}$  64° (181 mg in 2 cc CHCl<sub>3</sub>)) of *hydroxybismorcholic acid*, m 295.8 (decompn) (*Me ester*, m 140). Catalytic reduction of II gives *hydroxybismorcholic acid* (IV), m 191, sapon gives

the *1-HO deriv* (V), m 270°. Hydrogenation of III gives the *Me ester* of IV, m 132.3°. Oxidation of V gives a *ketobismorcholic acid* (VI), m 244.6°, reduced by

Clampson's method to an acid,  $C_{11}H_{16}O_4$ , in 213.4° (Me ester, in 100°,  $[\alpha]_D^{20}$  8° (14.5 mg in 2 cc  $CHCl_3$ )), this is *isovallocholonic acid* (VII), which is also obtained from norallocholonic acid (Chuang, *C A* 27, 215) by the action of  $CH_3N$ , followed by  $PhMgBr$  and oxidation of the resulting carbinol with  $CrO_3$  in  $AcOH$ , the acid is optically inactive. C. J. West.

**Taurocholic acid** Ioshiyuki Tanaka *Z physiol (chem)* 220, 39 12(1933) Hammersten's method of prep. taurocholic acid from bile yields the Na salt instead of the free acid. This accounts for the discrepancy in phys. properties between Hammersten's prep. and the synthetic acid described by Bomer and Muller. H's acid must have been the Na salt of taurocholic acid, with acid properties due to fatty acid present in cholic acid combination. Na taurocholate, in 180°, when boiled with  $H_2O$  rearrange to an isomeric form, in 230°, without change in soly or sp. rotation. The isomer gradually reverts to the original form when rapidly recryst. several times from cold  $H_2O$  and  $H_2O$ . Hydrolysis by 5%  $KOH$  yields cholic acid and taurine. A. W. Dow.

**Intermediate products in the Hammarsten reaction of cholic acid** Kazumi Yamasaki *Z physiol (chem)* 220, 42 9(1933) The Hammarsten reaction, whereby cholic acid on treatment with concd.  $HCl$  gives a blue violet color, is a dehydration which proceeds through intermediate step. When the reaction is performed in  $AcOH$  soln and in excluded, 3 intermediate products can be isolated. These are apocholic acid, dihydroxycholeonic acid and a new acid is *dihydroxycholeonic acid*, in 198°,  $[\alpha]_D^{20}$  9.2°. The last contains a double linkage which is resistant to catalytic hydrogenation, but unlike apocholic acid it does not form mol. compd. with solvents or other substances. It gives a blue color with dil.  $Br$  in  $AcOH$ . It may be obtained also by treatment of apocholic acid with concd.  $HCl$ , hence is not the 1st intermediate, but a rearrangement product of apocholic acid. Treatment of cholic acid with  $SnCl_4$  as well as with  $ZnCl_2$  yields apocholic and dihydroxycholeonic acids, and on standing, the mixt. take on the blue violet color of the Hammarsten reaction. A. W. Dow.

**3 Phenyl  $\beta$  (9,10 dihydro 10 keto 9 anthryl) propionic acid** Synthesis of 3, 9,10 dihydro 10 keto 9 anthryl  $\alpha$  hydriodone Luckenbach *Natural products* 57, 181 9(1933) *Central lab. sup. chem. univ. (L'aval) Q. B. 1933* No. 2, 0 pp. Diethyl benzylidene malonate (I), b. 184.1°, b. 146.1°, is obtained in 80% yield by condensation of equimol. quantities of  $BzH$  and diethyl malonate via Knoevenagel (*Ber* 21, 285 9, 181 11). Diethyl chlorobenzylidenemalonate (II), m. 80°, b. 182°, is obtained in 8% yield by condensation of chlorobenzaldehyde and diethyl malonate in presence of piperidine. The di Me ester (III), m. 58.9°, b. 141°, is similarly obtained in 65% yield. Diethyl  $\beta$  phenyl  $\beta$  (9,10 dihydro 10 keto 9 anthryl) succinate (IV), m. 101°, sol. in  $C_6H_6$ ,  $MeCO$ ,  $CHCl_3$ ,  $MeOH$ ,  $H_2O$ ,  $H_2O$ .

very lightly sol. in petrole ether, ol. in the cold in  $H_2SO_4$ , giving a greenish yellow soln, is obtained in 30% yield by condensation of anthrone (crystd. from  $C_6H_6$  and free from  $AcOH$ ) with I in presence of piperidine. Diethyl  $\beta$  2 chlorophenyl  $\beta$  (9,10 dihydro 10 keto 9 anthryl) succinate (V), m. 119.20°, sol. in  $H_2O$  and  $MeOH$ , is obtained in 72.6% yield from anthrone and II in presence of piperidine. The di Me ester (VI), m. 118.3°, sol. in  $C_6H_6$ , is similarly obtained in 82.6% yield from III.

$\beta$  Phenyl  $\beta$  (9,10 dihydro 10 keto 9 anthryl) propionic acid (VII), m. 190.7°, is obtained in 82% yield reduced to about 30% on recrystn. from  $AcOH$  by refluxing IV with 7 parts 30%  $H_2SO_4$  + 3 parts glacial  $AcOH$  for 4-6 days, the time for completion of the reaction can be reduced by about 2 days by seeding with pure crystals at the end of 2 days.

$\beta$  (2 Chlorophenyl)  $\beta$  (9,10 dihydro 10 keto 9 anthryl) propionic acid, in 161°, ol. in  $AcOH$ , very sol. in  $H_2O$ , is obtained by saponifying VI with  $AcOH$  and 30%  $H_2SO_4$  and refluxing for 5-6 days.  $\beta$  Phenyl  $\beta$  (9,10 dihydro 10 keto 9 anthryl) propionyl chloride (VIII), m. 116°, sol. in  $CS_2$ , slowly converted into VII on exposure to air, almost quant. con-

verted into VII by boiling with  $AcOH$ , is obtained in 90.4% yield by refluxing VII and  $PCl_5$  in  $C_6H_6$  for about 1 hr, it is also formed with  $PCl_5$  but is difficult to purify owing to the formation of resins. The Me ester of VII, m. 112°, is obtained in 84.6% yield by refluxing VII with  $PCl_5$  in anhyd.  $C_6H_6$ , cooling and gradually adding anhyd.  $MeOH$ . 11 ester (69.5% yield, m. 89°, amide, m. 182°, very sol. in  $C_6H_6$  and  $H_2O$ , insol. in petrole ether, amide, m. 169°.

**10 Keto 9 ( $\alpha$  phenyl  $\beta$  benzoylthyl) 9,10 dihydroanthracene (IX)**, m. 115-16°, is obtained by adding  $AlCl_3$  to a  $C_6H_6$  soln of VIII, stirring for 3 hrs. at 20°, boiling 3 hrs. with turning, cooling, pouring on ice, acidifying with  $HCl$ , steam distg. the  $C_6H_6$ , taking up the residue in as little boiling  $AcOH$  as possible, cooling, filtering, evapg. the filtrate to dryness, and purifying by dissolving in  $EtO$ , washing with  $NH_4OH$ , evapg. the  $EtO$  and recrystg. from  $H_2O$ . The insol. residue filtered out of the  $AcOH$  soln of IX consists of a mixt. of 2 tautomeric forms of (9,10 dihydro 10 keto 9 anthryl)  $\alpha$ -hydriodone (X), which was sep'd by repeated fractional crystallization from  $MeOH$  into large lozenges, m. 161.2° (ketone form) and monoclinic plate in 187.8° (enol form). By carrying out the above Friedel and Crafts reaction in  $CS_2$  instead of  $C_6H_6$  soln, formation of IX is eliminated, the X is obtained practically pure in 75% yield after a single cry. from  $C_6H_6$  and consists almost exclusively of the ketonic form. It is slightly sol. in  $EtO$  and  $CS_2$ , more sol. in  $MeOH$  and  $H_2O$ , very sol. in  $C_6H_6$  and  $CH_2$ , crystallizes from  $H_2O$  in lozenges and from  $CS_2$  and  $C_6H_6$  in needles containing part of the solvent in combination, sol. in cold concd.  $H_2SO_4$  to a greenish yellow soln from which it is pptd. unchanged on diln, in contact with concd. alkalis it acquires a marked reddish brown coloration and partially dissolves. The ketone form only is obtained by dehydrating VII with concd.  $H_2SO_4$  heating for 3 min. at 110°, pouring on ice, filtering, drying and recrystg. from  $C_6H_6$ . Both forms of X give the same mon. bism. deriv., m. 141°, very slightly sol. in hot  $CS_2$  and  $EtO$  and easily sol. in hot  $H_2O$  and  $MeOH$ . The hydrazine hydrate of X in 146° (decomps.), phenyl hydrate in 224°, cryt. from  $C_6H_6$  with 1 mol. solvent semicarbazone in 24°, oxime, crystg. with 1  $C_6H_6$ , m. 181°, very sol. in  $H_2O$  and  $EtO$ , less sol. in  $C_6H_6$  and  $C_7H_8$ . Oxidation of X by  $CrO_3$  via Fiebermann and Rokit (*Ber* 41, 112, 7(1908)) and Hilkey and Matvel (*C A* 27, 67) give almost exclusively anthraquinone. Oxidation by  $HNO_3$  (d. 1.2) via Koenig (*Ann* 275, 541 1(1885)) gives anthraquinone and phthalic acid in amts. proving that the latter is formed from the hydriodone nucleus and not by oxidation of the anthraquinone formed. All yields given are based on theoretical. A. Papirer and Confort.

**Tetrahydroxybufostan, a tetrahydric alcohol  $C_{17}H_{24}O_4$ , from the winter bile of toads** Hiroshi Makino *Z physiol (chem)* 220, 49 54(1933) The winter bile of the toad, *Bufo vulgaris japonica*, contains a pale tetrahydroxybufostan, m. 230°,  $[\alpha]_D^{20}$  57°, which resembles both cholesterol and cholic acid and may be regarded as a transition form between the sterols and the bile acids. The substance does not add  $Br$  and cannot be hydrogenated catalytically. It gives the Pettenkofer and the Hammarsten Yamasaki reaction, but not the Fiebermann-Burckard or the Salkowski reaction. With  $AcO$  it formed a tetraacetate, m. 32°, which could not be obtained cryt. Oxidation in  $AcOH$  by  $CrO_3$  converted the alk into a tritomonocarboxylic acid,  $C_{17}H_{24}O_4$  m. 221.2°,  $[\alpha]_D^{20}$  31° (11 ester, could not be cryt'd). Me ester, m. 198.9°, bisoxime of 11 ester, m. 218°. trioxime of Me ester, m. 214.5°. The alk contains 3 secondary and 1 primary OH, the latter in the side chain. A. W. Dow.

**The viologen indicators** I. Michaels and Edgar S. Hill *J. Gen. Physiol.* 16, 859 75(1933) Viologens, quaternary bases, derived from  $\gamma,\gamma'$ -dipyridyl, are useful oxidation-reduction indicators for biol. purposes. Their p.d. range is very mg., they are colored in the reduced form, and their oxidation-reduction p.d. is independent of the pH.  $\gamma,\gamma'$ -Dipyridyl is prep'd by agitating a mixt. of anhyd. pyridine, 25%  $CCl_4$  and 50 g.  $Zn$  dust

The yellow ppt. is dissolved by heating on a water bath at 90°, the liquid is crystd. in the cold, and the crystals are exposed to the air at 50°. After several days, colorless crystals of the compd. appear in a brown mass. The entire mass is dissolved in boiling water made alk. with NaOH. The filtered soln. is crystd. at low temp. The compd. is recrystd. by dissolving in hot slightly acidified water and pptg. with NaOH. It contains 2 mols. water which are lost at 50°. The m. p. of the anhyd. compd. is 110–112°. To test for  $\gamma, \gamma'$ -dipyridyl, dissolve a small amt. of 50% AcOH and add some solid  $\text{CrCl}_3$ . An intense violet color indicates the presence of the compd. Zn dust may be used in place of  $\text{CrCl}_3$ , but the violet color is transient, reduction proceeding to the colorless state. *N, N'*-Dimethyl- $\gamma, \gamma'$ -dipyridinium dichloride (methylviologen) is prepd. from  $(\text{CH}_3)_2\text{SO}_4$  and  $\gamma, \gamma'$ -dipyridyl by heating the mixt. to boiling, cooling, and again heating in the same way. After removing the excess  $(\text{CH}_3)_2\text{SO}_4$  with  $\text{Et}_2\text{O}$ , the aq. soln. is treated with an excess of feric acid, the picate is washed with acetone and suspended in 100 cc. acetone. A little concd. HCl is then added which gradually changes the picate to the colorless dichloride which is insol. in acetone. The dichloride is recrystd. by dissolving in MeOH and pptg. with a large excess of acetone. The yield, as colorless needles, is almost theoretical. At 50°, the compd. loses the water of crystn. Me viologen, dissolved in water, gives, on the addn. of  $\text{Na}_2\text{S}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  and  $\text{NH}_4\text{OH}$ , a blue to deep violet color.  $\gamma, \gamma'$ -Dipyridyl does not give this test. *N, N'*-Diethyl- $\gamma, \gamma'$ -dipyridinium dichloride (ethyl viologen) is similarly prepd. from  $\gamma, \gamma'$ -dipyridyl and  $(\text{Et})_2\text{SO}_4$ . *N, N'*-Dibenzyl- $\gamma, \gamma'$ -dipyridinium dichloride (benzyl viologen) is similarly prepd. with  $\text{BzCl}$ . Prepn. of the picate is not necessary, and it does not crystallize so easily as the others. *N, N'*-Dibetaine- $\gamma, \gamma'$ -dipyridinium dichloride (betaine viologen) is prepd. by melting  $\text{ClCH}_2\text{COOH}$  in a test tube and adding  $\gamma, \gamma'$ -dipyridyl, bringing the mixt. quickly to boiling, and holding at this temp. a short time. The soln. is then mixed with a large excess of acetone and a few drops of concd. HCl. Betaine viologen crystallizes from this soln., and is recrystd. from MeOH soln. by the addn. of an excess of acetone or  $\text{C}_6\text{H}_6$ . The normal p. ds. of these indicators at 30° referred to the normal H electrode are, within  $\pm 0.002$  v.: Me viologen  $-0.446$  v., Et viologen  $-0.449$  v., betaine viologen  $-0.444$  v. and Bz viologen  $-0.359$  v. If the soln. under test produces a coloration of these indicators to the extent of  $A\%$  of the max. color, the oxidation-reduction p. d. is  $E = E_0 - 0.06 \log A/100-A$ , where  $E_0$  is the normal p. d. of the indicator which is independent of the  $p_{\text{H}}$ . C. H. Richardson.

**Color and structure of oximes and semicarbazones.** Mine. Ramart-Lucas and Marthe Grumez. *Bull. soc. chim.* 53, 753 9 (1933). See C. A. 27, 712. G. G.

**Lignin (Brauns, Hibbert) 23.** Cellulose. XLIX. (2) Methylation of cellulose fibers. I. Diethylglucose from partially ethylated cellulose. LI. Esterification of cellulose with tosyl chloride in the presence of pyridine (Hess, et al.) 23. Behavior of dipeptides contg.  $\alpha$ -amino- $n$ -heptylic acid toward trypsin and crepsin (Abderhalden, Broich) 11A. Raman effect in terpene compds. (Dupont, et al.) 3. Raman effect. XXVI. **Fischer, Emil:** Introduction to the Preparation of Organic Compounds. Translated from the 8th German ed. by R. V. Stanford. New York: D. Van Nostrand Co., Inc. 175 pp. \$2.00.

**Moore, F. J.:** Outlines of Organic Chemistry. 4th ed., revised by William T. Hall. New York: J. Wiley & Sons, Co., Inc. 338 pp. \$2.75.

**Oxygenated organic compounds from carbon monoxide and hydrogen.** I. G. Farbenind. A.-G. (Franz Lappe,

Mathias Pier, Wilhelm Rumpf and Georg Stern, inventors). Ger. 580,695, July 14, 1933. Addn. to 559,802 (C. A. 27, 730) and 490,248 (C. A. 24, 2137). The parts of the app. which come into contact with CO are made of or lined with steel contg. a substantial proportion of Mn.

**Hydrating olefins.** Henry Dreyfus. Brit. 394,375, June 22, 1933. The hydration of olefins with the production of alcs. or ethers is effected by passing olefins and steam in contact with pyrosulfates that are stable under the reaction conditions, especially alkali pyrosulfates. The temp. may be 100–350° or more and pressure up to 25 atm. or more may be used. For the production of  $\text{Et}_2\text{O}$  2 or more vols. of  $\text{C}_2\text{H}_4$  to 1 of steam may be used while for alc. equal vols. are suitable.  $\text{H}_2\text{O}$  may be used instead of steam. In 394,389, June 22, 1933, divided out of 394,674, the mixt. of olefin and steam is led through a phosphoric acid which is initially substantially anhyd. In 394,674, June 22, 1933, the mixt. is passed in contact with a liquid or molten catalyst compn. comprising a phosphate, e. g., an alkali metaphosphate or a mixt. of Na and Li metaphosphates. Other substances may be added to the bath, especially those having a low m. p.

**Catalytic oxidation of organic compounds.** Alphon O. Jaeger (to Selden Co.). U. S. 1,930,716, Oct. 17. Reactions such as the production of phthalic anhydride by oxidation of naphthalene with air are effected at a suitable temp. by use of an oxidation catalyst such as one contg. V together with SiC, Ti carbide or Zr carbide, serving as activators.

**Dehydrating organic liquids.** I. G. Farbenind. A.-G. Brit. 394,080, June 22, 1933. The vapors of the liquids are subjected to the action of anhyd.  $\text{CaSO}_4$  obtained by heating plaster of Paris or gypsum to 160–180° or higher, the anhyd. sulfate being used in such amt. as to be converted to  $\text{CaSO}_4 \cdot 1/2\text{H}_2\text{O}$ . The process is particularly applicable to liquids with b. p. near that of  $\text{H}_2\text{O}$  or forming azeotropic mixts. or decomposing when heated with  $\text{H}_2\text{O}$ , e. g., acetal, AcH, aldehyde-ammonia,  $\text{HCOOH}$ , amylene hydrate, crotonaldehyde, AcOH, iso-BuOH,  $\text{PrOH}$ , iso- $\text{PrOH}$ ,  $\text{EtOH}$ , piperidine, pyridine, chloral, chloroacetone, cyclohexanol. App. is described.

**Catalytic hydrogenation.** The Goodyear Tire & Rubber Co. Brit. 395,231, July 13, 1933. Heterocyclic compds. contg. N in the nucleus are hydrogenated under pressure in the liquid phase in presence of a Ni catalyst prepd. according to Brit. 394,576 (cl. C. A. 28, 270). Pressures of 100–220 atm. and a temp. of 225° may be used. Solid compds. may be dissolved in an inert solvent such as a satd. hydrocarbon. Examples describe the conversion of  $\alpha$ - and  $\beta$ -picolines to  $\alpha$ - and  $\beta$ -pipercolines, quinoline to tetrahydro- and decahydro-quinolines,  $\alpha$ -benzylpyridine to  $\alpha$ -benzylpiperidine, pyrrole to pyrrolidine,  $\alpha$ -pyridylphenylethylene to 2-phenethylpiperidine,  $\gamma$ -pyridylphenylethylene to 4-phenethylpiperidine and pyridine to piperidine. In 395,232, July 13, 1933, primary aromatic amines, e. g.,  $\text{PhNH}_2$ ,  $\gamma$ - and  $\beta$ -naphthylamines, benzidine, toluidines, xylidines, *o*-ethylphenylamine, toluidine, cumidylphenylamines, are similarly hydrogenated.

**Chlorinating arylamines.** Emeric Havas and Henry R. Lee (to E. I. du Pont de Nemours & Co.). U. S. 1,930,754, Oct. 17. For prepg. a *p*-chloroarylamine compd. of the benzene series such as 5-chloro-2-aminotoluene, a chlorinating reagent such as Cl is caused to react upon a formylaminoaryl compd. such as the formyl deriv. of *o*-toluidine in an anhyd. benzenoid solvent which is substantially inert to Cl, and aq. non-oxidizing inorg. acid such as HCl is added to effect hydrolysis of the formyl group, and the resulting pptd. salt of the *p*-chloroarylamine is recovered.

**Alcohols.** Henkel & Cie., G. m. b. H. Brit. 395,198, July 13, 1933. See Fr. 743,358 (C. A. 27, 3721).

**Alcohols.** N. V. de Bataafsche Petroleum Maatschappij. Brit. 395,202, July 13, 1933. In producing alcs. from olefins and  $\text{H}_2\text{SO}_4$ , the alc.- $\text{H}_2\text{O}$  mixt. obtained is completely or substantially dried, e. g., by  $\text{CuSO}_4$ ,  $\text{CaO}$  or  $\text{CaCl}_2$ , or by azeotropic distn. with PhMe, xylene, ethylene chloride, benzene fractions, etc., before the final

distn. which is then effective for sepg. the alc. from unpleasant-smelling polymers. In examples (1) crude aq. isopropyl alc. is concd. to 88% strength by azeotropic distn., dried with anhyd.  $\text{CuSO}_4$ , and fractionally distd. and (2) the same crude alc. is dehydrated by distn. with PhMe, with return of the PhMe layer of the condensate, and is then fractionally distd. Cf. *C. A.* 27, 4022.

**Alcohols, ethers and esters.** Henry Dreyfus. Brit. 394,376, June 22, 1933. See Fr. 746,463 (*C. A.* 27, 4539).

**Alcohols and aluminum sulfate.** Wm. S. Wilson (to Merrimac Chemical Co.). U. S. 1,931,014, Oct. 17. Alcs. such as EtOH are formed by hydrolyzing alkyl sulfate esters such as  $\text{Et}_2\text{SO}_4$  in the presence of bauxite and water.

**Higher alcohols.** I. G. Farbenind. A.-G. (Wilhelm Pungs and Karl Behringer, inventors). Ger. 583,323, Sept. 2, 1933. Higher alcs. are recovered from mixts. with higher acids by fractionally distg. the mixts. under reduced pressure with the aid of steam or the vapor of an org. liquid such as  $\text{C}_6\text{H}_6$  or EtOH. The mixts. to be treated may be those obtained by sapon. waxes, or by reducing higher fatty acid esters, or by oxidizing paraffin wax. Examples are given.

**Halogenated alcohols.** Hans Meerwein and Erich Goth (to Winthrop Chemical Co.). U. S. 1,931,204, Oct. 17. Reduction of halogenated aldehydes to the corresponding halogenated alcs. is effected (suitably in the presence of a non-tertiary alc. such as isopropyl or isobutyl alc., cyclohexanol, Et, Pr or benzyl alc.) with an alcoholate of a metal other than Al (preferably alcoholates such as those of Zr, Ti, Sn and Fe, although alcoholates such as those of B, Li, Pb, Mn, Co and Ni also may be used). Various details, modifications and examples are given.

**Purifying and separating monohydric terpene alcohols and hydroaromatic alcohols.** Howards & Sons Ltd., John W. Blagden and Walter E. Huggett. Brit. 394,979, July 4, 1933. See Fr. 744,175 (*C. A.* 27, 3943). The purification of menthols according to Brit. 376,356 (*C. A.* 27, 3946) is excluded.

**Polyvinyl alcohol derivatives.** I. G. Farbenind. A.-G. (Arthur Voss, inventor). Ger. 526,497, Sept. 25, 1933. Water-sol. polyvinyl alc. prep'd. by sapon. a polyvinyl ester, is converted into water-insol. products by heating, e. g., to 160°, and (or) by treatment with reagents capable of pptg. aluminums, e. g., tannin or  $\text{CH}_3\text{CO}$ . The products may be used for making films or molded articles. Examples are given. Cf. *C. A.* 27, 3483.

**Tertiary alkylarylamines.** Werner Muller (to General Aniline Works). U. S. 1,930,855, Oct. 17. Alkylol-alkylarylamines in nearly theoretical yields are obtained by acting with an alkylene oxide in a closed vessel upon a secondary alkylarylamine at 100–180° (preferably about 140–150° in most instances). Details are given of the production of 1-(phenylethylamino)butane,  $b_{10}$  160°, 1-(phenylpropylamino)butane,  $b_{10}$  158°, 1-(phenylethylamino)-2-methylpropane,  $b_{10}$  153°, 1-(phenylethylamino)-1-methylpropane,  $b_{10}$  152°, 1-(*o*-methylphenylamino)butane,  $b_{10}$  148°, ethylol-ethyl-1-naphthylamine,  $b_{10}$  187.8°, hydroxyethylmethyl-2-naphthylamine,  $m$  37.9°, propylolcyclohexylaniline,  $b_{10}$  176°, butylol-ethylamine,  $b_{10}$  142°, and butylol-*n*-butylamine,  $b_{10}$  160°. These compds. generally may be used as dye intermediates.

**Aromatic hydroxy aldehydes.** F. Hoffmann-La Roche & Co. A.-G. Ger. 580,981, July 19, 1933. Addn. to 578,037 (*C. A.* 27, 4241). Hydroxybenzyl alcs. are oxidized by the process of Ger. 578,037. Examples are given. Cf. *C. A.* 27, 2692.

**Ketones.** Wilhelm Quersfurth (to Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler). U. S. 1,929,331, Oct. 3. A mixt. of ketonizable substances including  $\text{C}_2\text{H}_2$  and EtOAc, EtOH, HOAc or acetaldehyde, and water vapors is passed at a high temp. (suitably about 400–550°) in contact with a heavy metal oxide catalyst such as Fe and Mn oxides in order to form acetone, etc.  $\text{Bq-CO}$ , etc., may also be used with the catalyst.

**Alkyl esters from olefins.** Robert M. Isham (75% to

Wm. B. Pine). U. S. 1,929,870, Oct. 10. Olefins such as those from cracked gasoline or  $\text{C}_4\text{H}_{10}$  are caused to react with a sulfonic acid such as benzenesulfonic acid to produce sulfonic esters and the latter are caused to react with an org. carboxylic acid such as HOAc to produce org. acid esters. The materials are agitated while maintaining the reaction temp. between about 25° and about 100° until the reaction is substantially complete, the sulfonic acid is allowed to settle out of the hydrocarbon materials, the latter are removed, and the esters are recovered by distn.

**Esters of phosphoric acid.** Erik Clemmensen (to Monsanto Chemical Co.). U. S. 1,931,056, Oct. 17. Refining of phosphate esters such as crude triphenyl phosphate is effected by treating the crude ester with a water-sol. permanganate.

**Esters of phosphoric acid.** Erik Clemmensen (to Monsanto Chemical Co.). U. S. 1,931,058, Oct. 17. Esters such as phenyl phosphates, obtained by the condensation of  $\text{POCl}_3$  and a phenol with the elimination of HCl, are refined by treating the crude ester with a water-sol. permanganate. U. S. 1,931,059 relates to a similar refining of neutral esters such as crude tritoly phosphate contg. naphthalenic impurities, the latter being decompd. by use of an aq. permanganate soln. (suitably at a temp. of about 80–100°).

**Sulfuric esters of anthrahydroquinones.** David A. W. Fairweather and John Thomas (to Scottish Dyes, Ltd.). U. S. 1,929,866, Oct. 10. In the esterification of anthrahydroquinone, one of the hydroxyl groups is protected by ester formation (as by introduction of an acetyl or benzoyl group) for the formation of monosulfuric esters. The remaining hydroxyl group may be esterified to form the sulfuric ester by use of pyridine- $\text{SO}_3$  in the presence of a tertiary base, and, if desired, the disulfuric esters formed may be hydrolyzed to form monosulfuric esters. Various details of procedure are given. Cf. *C. A.* 27, 3482.

**Tetrasulfuric acid ester of leuco-1,2,2',1'-anthraquinonazine.** I. G. Farbenind. A.-G. Brit. 394,887, July 6, 1933. Tetrasulfuric acid ester of leuco-1,2,2',1'-anthraquinonazine is prep'd. by reacting a compd. such as the disulfuric acid ester of anthrahydroquinone-2-sulfamic acid, or a salt thereof, with  $\text{PbO}_2$  or a ferriacyanide in a non-acid aq. medium, care being taken that sufficient alkali is present to avoid acid conditions developing during the reaction, e. g., by the addn. of hydroxides or basically reacting salts of  $\text{NH}_4$  or alkali or alk. earth metals. Among examples anthrahydroquinone-2-sulfamic acid 9,10-disulfuric acid ester Na salt is oxidized in presence of  $\text{Na}_2\text{CO}_3$  with  $\text{PbO}_2$  at 60–65°. The product may be used for unregulating fibers from a dye bath or used in a printing paste, acid oxidation yielding the dihydroazine dye.

**Refining crude phenols.** Erik Clemmensen and Roy M. Miller (to Monsanto Chemical Co.). U. S. 1,931,057, Oct. 17. Crude phenols such as phenol or cresols are distd. after adding a relatively small proportion of an inorg. base such as an alkali or alk. earth metal carbonate, bicarbonate, oxide or hydroxide.

**Amides of aromatic acids.** I. G. Farbenind. A.-G. (Heinrich Hopff, inventor). Ger. 584,142, Sept. 15, 1933. Aromatic carboxamides are prep'd. by treating mono- or di-nuclear aromatic hydrocarbons with a cyanate and a H halide in the presence of a catalyst of the kind used in the Friedel-Craft reaction. Thus, benzamide is obtained when a mixt. of benzene,  $\text{KCNO}$  and  $\text{AlCl}_3$  is treated at atm. temp. with HCl gas until  $\text{KCNO}$  cannot be detected in the mixt. Details are given also of the prep'n. of *p*-toluamide and *o*-naphthamide.

**Glucosides.** Burkhardt Helferich. Brit. 394,195, June 22, 1933. Glucosides of aromatic hydroxy compds. are prep'd. by condensing the acetates of reducing sugars with aromatic hydroxy compds. and sapon. the resulting Ac glucosides. The condensation is effected in the presence of an acidic substance and, if desired, a solvent, while the sapon. may be effected with alkali or  $\text{NH}_4$  or catalytically. Among examples  $\beta$ -phenolgalactoside is

prepd. by sapon. the tetraacetyl compd. obtained by condensing PhOH with  $\alpha$ -pentaacetylglucose with the aid of ZnCl<sub>2</sub> and  $\beta$ -thymoglucose by sapon. the tetraacetyl compd. obtained by condensing thymol with  $\beta$ -pentaacetylglucose in presence of  $p$ -toluenesulfonic acid.

**Lactones.** C. H. Boehringer Sohn A.-G. (Georg Schöning and Bruno Walach, inventors). Ger. 584,372, Oct. 18, 1933. Addn. to 575,023 (C. A. 27, 3484). This corresponds to Brit. 378,095 (C. A. 27, 3945), but includes the following addnl. examples: (1)  $p$ -methylcyclohexanone and  $\alpha$ -bromoisovaleric acid Me ester  $\rightarrow$   $\alpha$ -(4-methylcyclohexanol-1)isovaleric Me ester,  $b_{12}$  140.5°,  $\rightarrow$   $\alpha$ -(4-methylcyclohexenyl)isovaleric Me ester,  $b_{12}$  118.23°,  $\rightarrow$   $\alpha$ -(4-methylcyclohexenyl)isovaleric acid,  $b_{12}$  140.2°,  $\rightarrow$   $\alpha$ -(4-methylcyclohexanol-2)isovaleric acid  $\gamma$ -lactone,  $b_{12}$  148.52°; (2) menthone and CH<sub>3</sub>CHBrC(OMe)  $\rightarrow$   $\alpha$ -(2-isopropyl-5-methylcyclohexanol-1)-propionic acid Me ester,  $b_{12}$  142.5°,  $\rightarrow$   $\alpha$ -(2-isopropyl-5-methylcyclohexanol-2)propionic acid  $\gamma$ -lactone,  $b_{10}$  160°.

**Compounds of the "abietene family."** Clyde O. Henke and Malcolm Charlton (to B. I. du Pont de Nemours & Co.). U. S. 1,931,257, Oct. 17. A sulfonic deriv. of abietene, abietine or abietane is condensed with an aldehyde such as formaldehyde or benzaldehyde or a compd. of like reactivity such as paraformaldehyde or benzal chloride to form a product which may be used as a wetting, dispersing or tanning agent.

**Arylaminoanthraquinone compounds.** Walter C. Mealy (to E. I. du Pont de Nemours & Co.). U. S. 1,931,265, Oct. 17. An unsulfonated haloanthraquinone compd. such as 1-amino-2-methyl-4-bromoanthraquinone is condensed with an unsulfonated phenylamine such as  $p$ -toluidine in the presence of an acid-absorbing agent such as NH<sub>4</sub>OAc and an amidation catalyst to produce an arylaminoanthraquinone compd. such as 1-amino-2-methyl-4- $p$ -tolylaminoanthraquinone, the condensation being carried out in aq. suspension. Numerous examples with details of procedure are given.

**Diazo compounds.** I. G. Farbenind. A.-G. Fr. 750,619, Aug. 14, 1933. Diazo compds. of the formula RN.N(SO<sub>2</sub>R')NH<sub>2</sub>x (R is an unsulfonated aryl residue, R' is any cyclic residue, x is the residue of a carboxylic acid, the C of the -C(=O) being joined with the N atom of the imino group, n is 1 or 2, R and R' may be substituted, e. g., by an alkyl, alkoxy or halogen, the R may be substituted by acyl-, alkyl- or phenyl-amino and R' by COOH or SO<sub>2</sub>H) are prepd. from an extremely condensed, soln. contg. the diazotization constituent along with HCl and NaNO<sub>2</sub>, to which a condensed, aq. soln. contg. the aromatic sulfonic acid is added. Examples and a list of components are given.

**Chlorinating cyclic compounds.** F. Raschig G. m. b. H. (Walter Pahl and Wilhelm Mathes, inventors). Ger. 580,512, July 13, 1933. Addn. to 575,765 (C. A. 27, 5082). The process of Ger. 575,765 is carried out at a temp. of at least 300° with catalysts consisting solely of Cu or its compds. Examples are given.

**Fluorine compounds.** I. G. Farbenind. A.-G. Brit. 395,227, July 13, 1933. Aromatic compds. fluorinated in the side chain are made by interaction between practically anhyd. HF and the corresponding compds. chlorinated in the side chain. In examples  $p$ -chlorobenzotrichloride, 1,3-bis(trichloromethyl)benzene, 1,4-bis(trichloromethyl)benzene,  $o$ -chlorobenzotrichloride and 2,1-dichlorobenzotrichloride are thus fluorinated, the products being the corresponding  $\omega$ -trifluoromethyl derivs., with  $p$ -chlorobenzodifluoride-chloride and  $p$ -chlorobenzoic acid as by-products in the first case. The products may be converted by customary methods into nitro- and amino-trifluoromethyl derivs. Cf. C. A. 27, 4414.

**Pyridino compounds.** I. G. Farbenind. A.-G. Brit. 394,416, June 29, 1933. Amines of 1-, 2- or 3-ring aromatic compds., which in the case of 1-ring compds. should be free from OH or alkoxy groups attached to the nucleus and in the case of 3-ring isocyclic aromatic compds. do not contain keto groups in  $\beta$ -position to each other, are quinolized by treating with glycerol in the presence of an oxidizing agent in 40-70% H<sub>2</sub>SO<sub>4</sub>.

When the glycerol is added gradually at practically the same rate as consumed by condensation the concn. of the H<sub>2</sub>SO<sub>4</sub> may be increased to 85%. Suitable oxidizing agents are aromatic NO<sub>2</sub> compds., e. g., PhNO<sub>2</sub>, nitrobenzenesulfonic acid and H<sub>2</sub>AsO<sub>4</sub>. Substances assisting oxidation, e. g., VCl<sub>5</sub>, SeO<sub>2</sub>, may be added. Examples describe the quinolizing of PhNH<sub>2</sub>,  $p$ -toluidine,  $o$ - and  $p$ -chloroaniline, 2,5-dichloroaniline, 3,4,5-trichloroaniline,  $o$ -nitroaniline,  $p$ -aminobenzoic acid,  $p$ -aminoacetanilide (to pseudophenanthroline (I)),  $p,p'$ -diaminobenzophenone,  $\alpha$ -naphthylamine, 2,8-aminohydroxy-naphthalene-6-sulfonic acid, 6-aminoquinoline (to I), aminomaphthostyryl, 3,6-diaminoacridine, etc.

**Organic persulfo compounds.** Fleisch-Werke A.-G. Im Gerbstofffabrikation u. Chemische Produkte. Brit. 391,989, June 27, 1933. Org. derivs. of persulfuric acid of the type RSO<sub>3</sub>OOM, where R is an org. radical and

3 M a basic radical, e. g., a metal, are prepd. by the oxidation of aliphatic, aromatic, hydroaromatic and heterocyclic sulfonyl chlorides with peroxides in the presence of org. solvents and in substantial absence of H<sub>2</sub>O. Stabilizers used for H<sub>2</sub>O<sub>2</sub> and in the prepn. of peroxides and per-salts may be added before or during reaction or to the finished product. The products are sol. in H<sub>2</sub>O and slowly give off active O in its presence. Among examples (1) toluenesulfonyl chloride in C<sub>6</sub>H<sub>6</sub> is added to a suspension of Na<sub>2</sub>O<sub>2</sub>

4 in alc., intensive cooling with brine being used and (2) CaO, suspended in alc., is treated with a C<sub>6</sub>H<sub>5</sub> soln. of amyl naphthalenesulfonyl chloride. The Ca salt is obtained in flocculent form by diln. with H<sub>2</sub>O contg. a small amt. of size. The compds. may be used alone or with other compds. and have oxidizing, bleaching, emulsifying, wetting, disinfectant and insecticidal actions. In particular (a) persulfo compds. of higher aliphatic hydrocarbons and their derivs. are very effective wetting and emulsifying agents; thus in the degumming of raw silk

5 a soln. of 10 g. Na octadecylpersulfonate per l. of liquor may be used and (b) aromatic and hydroaromatic persulfonic acids and their salts, particularly those having an alkyl, aryl or aralkyl group on the side chain, show good bleaching and oxidizing action and high wetting power, thus unbleached, starch-sized cotton fabric may be de-sized and semibleached by treatment in a bath contg. 3 g.

6 Na diaminonaphthalenepersulfonate and 3 g. calcined soda per l., together with a small amt. of a Mg salt as a stabilizer. A soap powder for use in domestic washing consists of Na tetrahydronaphthalenepersulfonate 40, powd. curd soap 50 and Na<sub>2</sub>PO<sub>4</sub> 10%. For bactericidal and disinfecting purposes compds. derived from phenol or their halogen derivs. are particularly useful.

**Anthraquinone derivatives.** Scottish Dyes Ltd. Ger. 584,111, Sept. 15, 1933. See Brit. 330,215 (C. A. 24, 6031).

**Anthraquinonazine derivatives.** Durand & Huguenin A.-G. Ger. 580,531, July 12, 1933. Addn. to 579,327 (C. A. 27, 4542). Sulfuric esters of reduction products of halo-1,2,2',1'-anthraquinonazines are prepd. by the process of Ger. 579,327. An example is given.

**Halogen derivatives of the benzophenone and anthraquinone series.** I. G. Farbenind. A.-G. Brit. 394,990,

8 June 29, 1933. A halodimethylbenzophenone, where R is a residue of the C<sub>6</sub>H<sub>4</sub> series, which may be substituted but is unsubstituted in 1  $\alpha$ -position to the CO group, is caused to react with halogen under conditions such that the Me-H atoms are (nearly) completely exchanged for halogen atoms and the product is subjected to the action of a sapon. and ring-closing agent to form the corresponding haloanthraquinone-carboxylic acid or -aldehyde. Treatment of the halogenated products with agents having sapon. action

9 only, e. g., NaOH, yields halobenzophenone-carboxylic acid or -aldehyde derivs. and these may be subjected to the action of ring-closing agents to form the corresponding anthraquinone derivs. In examples (1) 2,6-dimethyl-4-chlorobenzophenone (prepd. by condensing 1,4-dimethyl-3-chlorobenzene with BzCl) is chlorinated in trichlorobenzene at 170-180° while being exposed to ultra-violet light from a Hg vapor lamp to give an  $\omega$ -hexachloro deriv.;

treating the product with concd  $H_2SO_4$  yields 2-chloroanthraquinone-3-carboxylic acid, whereas by using  $NaOH$  4-chlorobenzophenone-3,6-dicarboxylic acid is obtained and this can be ring closed as above, the chlorination can be interrupted when the  $\omega$ -protachloro deriv is formed and thus, on ring-closure with  $H_2SO_4$ , yields a mixt of 2-chloroanthraquinone-3-carboxylic acid and aldehyde which are sepd by adding  $Na_2CO_3$  and (2) 2,5,4-trimethyl-4,5-dichlorobenzophenone (prepd by condensing 2-chloro-*p*-xylene with 3-chloro-4-methylbenzoic acid chloride) is chlorinated as in (1) and the product treated with concd  $H_2SO_4$  to give 2,6-dichloroanthraquinone-3,7-dicarboxylic acid.

**Haloanthraquinone derivatives.** I. C. Liebenow & A. G. Brit 394,999, June 29, 1933. Divided on and addn to 391,990 (preceding abstr). Halogen dianthraquinonyl or halogen-diphthaloylnaphthalenes are obtained by nearly or completely halogenating in presence of a diluent and at time light the Me groups of a dihalo 2,2'-dimethyl-10,10'-dibenzophenonyl (obtainable by condensing a 1,4-biphenyldicarboxylic acid halide with a *m* halo toluene) or the Me groups of a 1,5-di(methylhalobenzoyl)naphthalene (obtainable by condensing a 1,5-naphthalenedicarboxylic acid halide with a *m* halotoluene), followed by treatment with a simultaneously saponic and ring-closing agent. In examples (1) the product obtained by condensing 1,4-diphenyldicarboxylic acid dichloride with chloro-1-methylbenzene (I) is completely halogenated in the Me group to give 2,2'-di-a-trichloromethyl-1,1'-dichloro-1,1'-dibenzophenone which is treated with concd  $H_2SO_4$  to give 2,7-dichloro-2,2'-dianthraquinonyl and (2) the product obtained by condensing I with 1,3-naphthalenedicarboxylic acid dichloride which is a mixt of isomeric 1,5-di(methylchlorobenzoyl)naphthalenes is chlorinated in the Me group as above and the product treated with concd  $H_2SO_4$ . Carboxylic acids which may have been formed by the sapon of the products obtained by chlorination of the 2-omer contg Me group in *p* position to the ketone group of the above compound removed with  $Na_2CO_3$ . 3,3'-bichlorodiphthaloylnaphthalene being produced.

**Metalliferous sulfurized phenol derivatives.** Valentin K. Kricheldorf to Chemische Fabrik vorm. J. Lindner (U. S. 1,931,010, Oct 12). Metalliferous sulfurized derivs of phenol which are easily sol in alk. soln and in water which give white-brown to black ppt. on addn of more alk. form difficulty of compd with alk. earth metal and heavy metal salt have mordanting, tanning and coloring properties, serve as insecticides and form lake with basic dyes are obtained by heating a phenol and mixt such as phenol, chlorophenols, phenolsulfonates, phenolcarboxylic acids, resorcinol, naphthol, fluoronaphthol, naphtholcarboxylic acid and sulfonic acid, with Sb in the presence of alkali metal salt of such acid that contain in the acid residue one or two metals (Li,  $NH_4$ ,  $Na$ ,  $HS$  group, such as all alkali metal, ammonium, phosphonium, antimonites, sulfantimonite, pyroantimonites, aluminates, arsenites, arsenates, chromates, plumbites, vanadates, zincates, molybdates, etc., and also O) and S contg complex salts like luto (Na) arsenosulfonate, Na chromomolybdate or dodecyl salts contg As and Sb, As and Bi, etc. Several examples with details of procedure are given.

**Condensation products of 1,5-dihaloanthraquinones.** Paul Nawaasky and Georg Kitzschmar (to General Aniline Works) U. S. 1,929,841, Oct 10. A 1,5-dihaloanthraquinone such as the 1,5-dichloroanthraquinone is condensed with an aminophenyl-carboxylic acid in the presence of a normally liquid salt (e.g. such as  $BuOH$ ) at temps above  $150^\circ$ , in order to form 1,5-dianthraquinoneanthraquinone or the like.

**Polyhydroxyfluorans.** Paul B. Woods, James Oakley and Frederick H. Kranz (to National Aniline & Chemical Co.) U. S. 1,931,049, Oct 17. In the production of a polyhydroxyfluorane such as fluorocum by the condensation of an  $\alpha$ -phthalic anhydride compd such as  $\alpha$ -phthalic anhydride with a polyhydroxybenzene compd contg a

free position ortho to one of the hydroxyl groups, such as resorcinol, the condensation is effected in a reaction mixt contg an inert org substance such as dichlorobenzene which is liquid at the temp of the reaction and serves as an "extender."

**Separating methylamines.** Rohm & Haas Co. Brit 394,475, June 29, 1933. Mixts of methylamines are sepd by first distg off trimethylamine as a const-boiling mixt with  $NH_3$ , the requisite amt of  $NH_3$  being added if not already present, or alternatively by adjusting the amts of mono and tri methylamine so that they come off as a const-boiling mixt and distg. After removal of the tri methylamine the mixt of mono and di-methylamine remaining can be sepd by fractional distn. The process is applicable to mixts contg other less volatile substances, e.g.,  $H_2O$ ,  $MeOH$ ,  $HCOONa$  or morg salts. Examples are given.

**Diketimides of *peri* indandiones and related nitrogen compounds.** Heinrich G. Gunc and Wilhelm Eckert (to General Aniline Works) U. S. 1,930,876, Oct 17. Diketimides of *peri* indandiones which are in general yellow to red compd, with intermediate formation of ketimides of  $\omega$ -cyanocetyl (both suitable for use in the manuf of dyes), are obtained by condensing compds such as malonic acid dinitrile, cyanoacetamide, malonic acid chloride or other compds which can be easily transformed into dicarboxylic acid dinitriles of the type of the malonic acid nitrile (suitably with use of a metal chloride condensing agent) with toluene, naphthalene, acenaphthene, 1-methylnaphthalene, anthracene or  $\alpha$ - or  $\beta$ -naphthol ether. Details of procedure are given for the production of the diketimides of *peri* acenaphthindandione, of *peri* naphthindandione, of 1,9-anthracene-methylindandione, of  $\alpha$ -methylnaphthindandione, of 2-methoxy-1,8-naphthindandione and some related compds.

**Complex metal salts of aliphatic polyhydroxy compounds.** I. C. Liebenow & A. G. Brit 395,005, July 7, 1933. Basic  $H_2O$  insol or difficultly  $H_2O$  sol alk. earth metal salts of complex compounds of aliphatic polyhydroxy compounds with trivalent Fe, Cr or Bi or Al are manufd by reacting upon in alk. reacting aq soln of a polyhydric alk, e.g., 1,1-ciol-cyclitol, xylitol, sorbitol, dulcitol, mannitol, or a polyhydroxy carboxylic acid, e.g., glyceric, tartaric, arabinic, mucic, saccharic, glucosaccharic, mannopentonic, lactobionic, with a salt or hydroxide of trivalent Fe, Cr, Bi or Al and pptg the complex metal compd formed by the addn of an alk. earth metal salt or hydroxide or by further mixing in alk. reacting soln of the polyhydroxy compd with the alk. earth metal salt or hydroxide and then adding the salt or hydroxide of the complex forming metal. Neutral  $H_2O$  sol salts of the metal complex compd are manufd by reacting upon the alk. earth metal salts with the calcd quantity of an alkali metal,  $M_2$ ,  $NH_3$  or amine salt, the mon of which forms alk. earth metal salts insol or sparingly sol in  $H_2O$ , e.g., salts of  $H_2SO_4$ ,  $H_2CO_3$  or oxalic acid such as Na or K sulfate or bisulfate, carbonate or bicarbonate, etc., or, in the case of the salts from polyhydroxy carboxylic acids, with 1 equiv of the free polyhydroxy carboxylic acid. Among examples (1)  $BiCl_3$  soln and  $FeCl_3$  soln are added to a soln of mannitol in aq  $NaOH$  to yield basic Bi ferric mannitol by treating in aq suspension of this with a soln of ethylenediamine sulfate or tetramethyl or tetraethyl ammonium sulfate or bisulfate the corresponding salts are obtained and (2)  $BiCl_3$  and a soln of  $BiCl_3$  are added to a soln of gluconic acid in aq  $NaOH$  to yield Bi gluconate on adding this to a gluconic acid soln a sol compd is obtained. In 395,004, July 7, 1933, divided on 395,005, complex compds of Sb with aliphatic polyhydric alcs are manufd by reacting on the alk. with a salt, oxide or hydroxide of tri- or quinquivalent Sb in the presence of an alkali or alk. earth metal hydroxide. The complex compds may be pptd by heating or by pptn with, e.g., alk. The alk. earth compds may be transformed into the corresponding alkali metal, tetraalkyl ammonium or alkylene diamine salts as described in 395,003. In example Sb $_2$ O $_3$  is added to a soln of sorbitol

in aq. NaOH to produce Na antimonyl sorbitol which is pptd. by addn. of alc. and (2)  $\text{Sb}_2\text{O}_3$  is added to a soln. of mannitol in aq.  $\text{Ba}(\text{OH})_2$  soln. to yield a ppt. of Ba antimonyl mannitol; the  $\text{Na}^+$  salt is obtained therefrom by treatment with  $\text{Na}_2\text{SO}_4$ , a compd. of quinquivalent Sb is obtained by replacing the  $\text{Sb}_2\text{O}_3$  by  $\text{Sb}_2\text{O}_5$ .

**Substituted guanidine salts of fatty acids.** Winfield Scott (to Rubber Service Laboratories Co.). U. S. 1,931,395, Oct. 17. Those members of the fatty acid series contg. from 14 to 20 C atoms which are but weakly acidic in nature, such as myristic, palmitic, stearic, arachidic acids, etc., and those acids derived from the unsatd. hydrocarbons such as oleic, linoleic, ricinoleic acids, etc., may be readily combined with the org. bases particularly the aryl substituted guanidines to produce salts, or org. soaps. Such compds. may be prepd. by mixing together the acid and the base in approx. equimol. proportions and preferably employing not over 6% excess of the fatty acid taken while heating to a temp., preferably slightly above the m. p. of the acid used. Thus, e. g., approx. 300 parts of stearic acid is heated to a temp. of about  $80^\circ$ , and 240 parts of di-*o*-tolylguanidine is added slowly thereto, with stirring. The heat evolved during the reaction is sufficient to maintain the temp. mentioned during this stage of the process. After all the guanidine has been added, the temp. is increased to approx.  $100^\circ$  and maintained thereat, preferably while stirring, for a time sufficient to insure the completion of the reaction. The stearate of di-*o*-tolylguanidine so obtained is a thick, sirup-like compd. when first prepd. On standing for a few hours, it solidifies to a stiff cake resembling stearic acid in consistency but of a darker color and possessing a lower softening point.

**Amine hydrohalides.** Newton Lamb (to Dow Chemical Co.). U. S. 1,929,950, Oct. 10. In forming an amine hydrohalide such as aniline-HCl from a gaseous H halide and an amine dissolved in a volatile org. solvent such as a mixt. of  $\text{C}_6\text{H}_6$  and  $\text{CCl}_4$  2 parts by vol. water, if present, is removed by distg. the solvent from the amine hydrohalide while absorbing uncondensed acid gas and solvent vapors in a fresh quantity of the amine and returning the latter to the process.

**Aliphatic fluoro halides.** Thomas Midgley, Jr., Albert L. Henne and Robert R. McNary (to Frigidaire Corp.). U. S. 1,930,129, Oct. 10. App. and details of operation are described for effecting reactions such as the replacement of Cl by F in  $\text{CCl}_4$  to form  $\text{CCl}_3\text{F}$  with fractionation of the desired product as it is formed.

**Diaryl sulfides.** I. G. Farbrund, A.-G. (Friedrich Muth, inventor). Ger. 583,055, Aug. 28, 1933. Di-(halohydroxyaryl) sulfides are prepd. by treating di- or tri-halophenols with a chloride of S in the presence of  $\text{AlCl}_3$ . Thus, 2,4-dichlorophenol, treated at atm. temp. in  $\text{CS}_2$  or  $\text{CCl}_4$  soln. with  $\text{S}_2\text{Cl}_2$  in the presence of  $\text{AlCl}_3$ , yields a di(dichlorohydroxyphenyl) sulfide m.  $188^\circ$ . Examples are given also of the prepn. of sulfides, m., resp.,  $177^\circ$ ,  $140^\circ$ ,  $285^\circ$ , and  $212^\circ$ , from 2,5- and 2,6-dichlorophenol, 2,4,6-trichlorophenol, and 2,4-dibromophenol.

**Formic acid.** Donald F. Othmer (to Eastman Kodak Co.). U. S. 1,930,146, Oct. 10. Propyl formate is used as a solvent for extg.  $\text{HCOOH}$  from its aq. solns.

**Purifying and decolorizing water-soluble organic acids such as maleic, fumaric, phthalic or naphthalic acids.** Alphons O. Jaeger and Lloyd C. Daniels (to Selden Co.). U. S. 1,930,054, Oct. 10. Acids such as those obtained by vapor phase catalytic oxidation processes are subjected, in aq. soln., to extn. with a plurality of solvents such as cresotic acid and  $\text{C}_6\text{H}_6$  at least one of which is partially dispersible with water and another substantially indispersible with water but miscible with the first solvent. The different solvents are successively applied in the order mentioned and are sepd. from the aq. layer and the purified acid material is recovered from the aq. soln.

**Acrylic acid.** Röhm & Haas A.-G. (Walter Bauer and Paul Weisert, inventors). Ger. 583,242, Aug. 31, 1933. See Fr. 713,261 (C. A. 26, 1622).

**Adenosinephosphoric acid.** Chemische und pharmaz-

eutische Fabrikation Georg Henning. Ger. 583,303, Sept. 1, 1933. Suitable animal organs are boiled with water, and during the boiling the mixt. is acidified with  $\text{AcOH}$ , then made feebly alk. with  $\text{NaOH}$ , and then weakly reacidified with  $\text{AcOH}$ . The filtrate is freed from inorg. phosphates by addn. of an alk. earth hydroxide, and the residue is concd. *in vacuo* to cause crystn. of an alk. earth salt of inosinic acid. Adenosinephosphoric acid is recovered from the mother liquor by crystn. Details are given.

**Apparatus for reactions such as production of benzoic acid from phthalic acid.** Frank A. Canon (to Selden Co.). U. S. 1,929,624, Oct. 10. Reacting materials are heated in a reaction chamber with a double cone-shaped bottom heated by burners and which may be filled with a material such as a Hg-Ph alloy which boils at the reaction temp. and is connected with a reflux condenser. Various structural and operative details are described.

***p*-2-Amylbenzoic acid.** Herman A. Bruson, Jack D. Robinson and Otto Stein (to Resinous Products & Chemical Co.). U. S. 1,930,449, Oct. 10. *p*-2-Amylacetophenone is boiled with  $\text{NaOCl}$  and acidified, to form *p*-2-amybenzoic acid, b. about  $140^\circ$ . Its Pb salt is suitable for use as a siccativ with oils.

**Succinic acid and anhydride.** Alphons O. Jaeger and Franz P. Fiedler (to Selden Co.). U. S. 1,929,381, Oct. 3. For purifying impure succinic acid contg. impurities which are relatively non-volatile, the acid is vaporized at a temp. above its m. p. and below its b. p., into a carrier gas stream such as air or  $\text{CO}_2$  and succinic acid, succinic anhydride or their mixts. is condensed from the carrier stream.

**Aliphatic anhydrides.** Henry Dreyfus. Brit. 304,689, June 30, 1933. Aliphatic anhydrides, e. g., of  $\text{AcOH}$ , propionic and alkoxy fatty acids, are produced by thermal decompn. of the corresponding acids in presence of catalysts comprising a phosphoric acid combined with a plurality of metals at least 1 of which is at least as electro-neg. as Ba. The metals may be present as basic or acid radicals. Among examples (1)  $\text{AcOH}$  vapor is preheated to  $500^\circ$  and passed through molten Na and K chlorides contg. K Ba tetrametaphosphate at  $700^\circ$  and (2) Ni phosphomolybdate, prepd. by heating Ni phosphate with  $\text{MoO}_3$ , is heated to  $200^\circ$  and suspended in glacial  $\text{AcOH}$  which is preheated under 10 atm. pressure at  $200^\circ$  and sprayed into a Cu-lined reaction chamber at  $700^\circ$ .

**Aliphatic acid anhydrides.** C. F. Boehringer & Soehne G. m. b. H. (Richard Müller and Erich Rabald, inventors). Ger. 580,930, July 19, 1933. Addn. to 566,332 (C. A. 27, 1011). Vapors of  $\text{CH}_3\text{CH}(\text{OAc})_2$  and its homologs are led at  $300$ – $350^\circ$  over the catalysts described in Ger. 566,332. Examples are given.

**Tetrachloroethylene and hexachloroethane from carbon tetrachloride.** Charles J. Strosacker and Clarence C. Schwegler (to Dow Chemical Co.). U. S. 1,930,350, Oct. 10.  $\text{CCl}_4$  vapors are contacted with an electrically heated body of resistor material such as granular carbon at a decomp. temp.

**$\alpha$ -Aryl- $\beta$ -aminoethanols.** Gordon A. Allen. U. S. 1,931,123, Oct. 17. For the isolation of compds. of this class (in which the aryl group may be phenyl, 4-methylphenyl, 4-methoxyphenyl, 3,4-dimethoxyphenyl or 3,4-methylenedioxyphenyl), the material is converted into a neutral sulfate by addn. of  $\text{H}_2\text{SO}_4$  and the sulfate is crystd. from a solvent such as water or alc.

**Furfural.** Kemiska Kontrollbyran Aktiebolag. (Bertil Groth and Georg Henning Blomqvist, inventors). Ger. 583,324, Sept. 1, 1933. Materials contg. pentosans are treated at  $100$ – $180^\circ$  with a relatively large amt. of dil. acid under such conditions that the furfural formed remains in the mixt. The liquid is then sepd. and furfural recovered by distn. App. is described. Cf. C. A. 27, 1012.

**Hexamethylenetetramine from methane.** Paul Nashan (to Gutehoffnungshütte A.-G.). U. S. 1,930,210, Oct. 10. A mixt. comprising  $\text{CH}_4$ , N and O is conducted through the visible non-dampened discharges of high-

tension, high-frequency a. c. to produce  $(\text{CH}_3)_3\text{N}_4$  and formaldehyde, followed by washing and heating in a crystg. tray to obtain  $(\text{CH}_3)_3\text{N}_4$  in solid form. An arrangement of app. is described.

**Chlorinating *o*-toluidine.** Emeric Havas and Henry R. Lee (to E. I. du Pont de Nemours & Co.). U. S. 1,930,751, Oct. 17. *o*-Toluidine is caused to react with formic acid to produce formylamino-*o*-toluene, the reaction product is chlorinated in a medium of  $\text{PhCl}$ , an aq.  $\text{HCl}$  soln. is added, and the mass is heated to effect hydrolysis and the resulting hydrochloride is recovered.

**Chlorinating *p*-xylydine.** Emeric Havas and Henry R. Lee (to E. I. du Pont de Nemours & Co.). U. S. 1,930,752, Oct. 17. *p*-Xylydine is converted into formylamino-*p*-xylene and the latter is then chlorinated (suitably by use of  $\text{Cl}$  in toluene soln.) to form derivs. such as 5-chloro-2-amino-1,4-xylene (which may be recovered as its hydrochloride).

**4-Alkyl-*o*-cresols.** Walter G. Christensen and Wm. S. Jones (to E. R. Squibb & Sons). U. S. 1,930,923, Oct. 17. In the production of a 4-alkyl-*o*-cresol such as 4-amylo-*o*-cresol, *o*-methylanisole is successively converted into methylnethoxyvalerophenone, amylo-*o*-methylanisole and amylo-*o*-cresol.

**Chlorinating cresidine.** Emeric Havas and Henry R. Lee (to E. I. du Pont de Nemours & Co.). U. S. 1,930,753, Oct. 17. In prepg. a 5-chloro-2-amino-4-methyl-1-anisole compd., a cresidine is chlorinated in which, as in 2-formylamino-4-methylanisole, the amino group is protected by an org. acyl group.

***peri*-Monooxynaphthalene.** Eugene Ayres (to Gulf Refining Co.). Brit. 394,511, June 29, 1933. *peri*-Monooxynaphthalene (I) is obtained by oxidizing  $\alpha$ -naphthol and extg. with  $\text{CaH}_2$  or by dehydrating 1,8-dihydroxynaphthalene under non-oxidizing conditions and extg. with  $\text{CaH}_2$ . I, its soln. in  $\text{C}_6\text{H}_6$ , the mixt. of I and bi- $\alpha$ -naphthol obtained from the oxidation of  $\alpha$ -naphthol and sublimation of unreacted  $\alpha$ -naphthol or the bi- $\alpha$ -naphthol itself may be added to fuels to inhibit gum formation. Examples are given.

**Synthetic hydrogenation menthol.** John W. Blagden. U. S. 1,930,411, Oct. 10. The menthol is partially converted into a menthol ester of an org. acid such as phthalic acid and the unchanged menthol and ester are sepd. (suitably by saponification and steam distn.) and the ester is saponified and the liberated menthol is recovered, in order to effect purification.

**1-Amino-5-methoxybenzothiazole.** Herbert A. Lubs and Arthur L. Fox (to E. I. du Pont de Nemours & Co.). U. S. 1,931,077, Oct. 17. This compd., white crystals m. about  $161^\circ$  to  $162.5^\circ$ , is formed from *p*-anisylthiourea by the action of halogenating agents such as  $\text{Cl}$ ,  $\text{SOCl}_2$ ,  $\text{S}$  chloride or  $\text{Br}$  and subsequent liberation of the free base by use of an alkali such as  $\text{NaOH}$ .

**2-Carbazyl ketones.** I. G. Farbenind. A.-G. Brit. 395,000, July 7, 1933. Acyl chlorides are caused to react on *N*-acetylcarbazole in presence of  $\text{AlCl}_3$  and  $\text{I}$  as catalyst; the *N*-acetyl group is subsequently saponified. An example of the treatment of *N*-acetylcarbazole with  $\text{AcCl}$  in  $\text{CS}_2$

soln., followed by sapon. to the ketone is given and  $\text{BzCl}$  is also specified.

**3,5-Diiodo-4-pyridones.** I. G. Farbenind. A.-G. Brit. 394,387, June 19, 1933. 3,5-Diiodo-4-pyridone is prepd. either by iodizing 4-pyridone or by iodizing 4-amino-pyridine and diazotizing the product or by decomposing  $\gamma$ -pyridylpyridinium chloride with  $\text{H}_2\text{O}$  and then iodizing. The product is a useful intermediate in the manuf. of x-ray contrast media. An example of each process is given.

**Pyranthrone.** Wm. Dettwyler (to E. I. du Pont de Nemours & Co.). U. S. 1,931,021, Oct. 17. 2,2'-Dimethyl-1,1'-bianthraquinonyl is heated with alc. potash in a closed vessel at a temp. below  $140^\circ$  (suitably about  $125^\circ$ ).

**Benzanthrone.** Alphons O. Jaeger and Lloyd C. Daniels (to Selden Co.). U. S. 1,930,681, Oct. 17. An impure anthraquinone from the catalytic oxidation of anthracene is subjected to condensation with glycerol to form a benzanthrone substance, and the product, without removal of alkali-insol. impurities, may be subjected to caustic alkali fusion in the presence of a reducing agent in order to form dibenzanthrone.

**Aminoanthrones and anthraquinones.** I. G. Farbenind. A.-G. Brit. 395,166, July 13, 1933. See Fr. 740,016 (C. A. 27, 2163).

**Quinizarin green and related compounds.** Walter C. Meuly (to E. I. du Pont de Nemours & Co.). U. S. 1,931,264, Oct. 17. A water-insol. 1,4-dihydroxy-anthraquinone compd. such as quinizarin, chloroquinizarin, purpurin or a corresponding leuco deriv. is condensed with aniline or a homolog to produce an aryl-aminoanthraquinone compd. in the presence of water.

**1,4-Diaminoanthraquinone.** Curt Bamberger and Paul Nawiasky (to General Aniline Works). U. S. 1,930,351, Oct. 10. 1,4-Diamino-2,3-dihydroanthraquinone dissolved in  $\text{H}_2\text{SO}_4$  (which may be of 50% or greater strength) is treated with an oxidizing agent such as  $\text{MnO}_2$  at a temp. (suitably  $10$  to  $15^\circ$ ) not exceeding that at which rearrangement of the 1,4-diamino-2,3-dihydroanthraquinone being formed occurs (the oxidizing agent being used in a quantity not greater than theoretically necessary to oxidize the 1,4-diamino-2,3-dihydroanthraquinone to 1,4-diamino-2,3-dihydroanthraquinone). The soln. is then heated to  $90$  to  $95^\circ$  and the melt is thereafter cooled and water is stirred in at a temp. not exceeding  $50^\circ$ . Colorless needles of 1,4-diaminoanthraquinone sulfate sep. and may be decompd. with water to obtain 1,4-diaminoanthraquinone. Various details and modifications of procedure are described.

**1,4-Aminohydroxyanthraquinone.** Curt Bamberger (to General Aniline Works). U. S. 1,930,352, Oct. 10. 1,4-Diamino-2,3-dihydroanthraquinone in 60-70%  $\text{H}_2\text{SO}_4$  is treated with slightly more than the required amt. of  $\text{MnO}_2$  for removing 2 H atoms from the initial material, at a temp. of  $80$  to  $100^\circ$ , and the reaction mixt. is treated with a reducing agent such as  $\text{SnCl}_2$  in at least sufficient amt. to reduce all of the quinonimine compd. formed to 1-amino-4-hydroxyanthraquinone.

## 11 - BIOLOGICAL CHEMISTRY

PAUL E. HOWE

### A - GENERAL

ARTHUR W. DOX

**Dehydrogenases during lysis of staphylococci.** Method for measuring bacteriolysis. Fernand Chodat and Fernand Wyss-Chodat. *Compt. rend.* 197, 657-60 (1933). Reduction time of methylene blue increases in direct proportion to the extent of the lysis. M. L. C. Bernheim

**Crystalline chlorocruorin.** Jean Roche and H. Munro Fox. *Nature* 132, 516 (1933).—Chlorocruorin, a respiratory pigment closely allied to hemoglobin and occurring only in the blood of certain polychete worms, is ob-

tained in cryst. form by the addn. of  $(\text{NH}_4)_2\text{SO}_4$  to blood at  $0^\circ$ . The crystals are rhombic, from pale yellow-green to dark brown-green in color, and exhibit strong red dichroism. The absorption spectrum of an oxychlorocruorin soln. resembles that for *Spirographis* blood. The percentage compn. of the chlorocruorin is compared with that of hemoglobin. The hematin part of the mol. is detd. to be greater for the former on a basis of the Fe content. Calvin Brous

**Urease activity as influenced by oxidation and reduction.** Leslie Hellefman, Marie E. Perkins and W. Mansfield Clark. *Proc. Nat. Acad. Sci.* 19, 855-60 (1933).—Urease

soln. was completely inactivated by the addn. of  $\text{Cu}_2\text{O}$  and again reactivated to 83% by excess  $\text{H}_2\text{S}$ .  $\text{Ph-CH}_2\text{HgCl}$  completely destroyed the activity which was again restored by excess  $\text{H}_2\text{S}$ . The effect is not due to the adsorption of enzyme on the suspended metallic deriva.  $(\text{ICH}_2)_2\text{Hg}$  caused no significant inactivation.  $\text{Cu}^{++}$  catalytically accelerates oxygenation of urease. Bzzymic activity is completely destroyed when solus. of urease contg.  $\text{Cu}_2\text{SO}_4$  or  $\text{Cu}_2\text{O}$  are aerated 3.5 hrs. The aeration effect is reversed partially by cysteine and completely by  $\text{H}_2\text{S}$ , thioglycolic acid and HS-glutathione.  $\text{I}^0$  but not  $\text{I}^-$  readily inactivates urease. Reactivation in this case is produced by  $\text{H}_2\text{S}$  but not by KCN.

R. Brown

Continued studies on the limits of specificity of protective enzymes. Differentiation of proteins from blood plasma or serum of various blood groups of healthy and diseased subjects and differentiation of homologous tissue proteins. Emil Abderhalden and Severian Budziszewski. *Fermentforschung* 14, 76-103 (1933); cf. *C. A.* 27, 2968. The urine of rabbits which have been injected subcutaneously with protein preps. from human sera representing different blood groups, and pos. and neg. Wassermann reaction, contains enzymes which are highly specific for the protein used. The presence of sarcoma, carcinoma and syphilitic infection alters the plasma proteins so that the Abderhalden reaction becomes specific for proteins of pathol. origin.

A. W. Dux

Further studies on the specificity of protective enzymes. Emil Abderhalden and Georg Eßkemann. *Fermentforschung* 14, 104-114 (1933); cf. *C. A.* 27, 2968. The urine of rabbits which had received subcutaneous injections of proteins and peptones prepd. from various organs of animals of different species (steer, horse, dog) contained enzymes which were specific not only for the organ substrate but also for the species of animal from which it was obtained.

A. W. Dux

The behavior of dipeptides containing  $\alpha$ -amino heptylic acid toward trypsin and erepsin. Emil Abderhalden and Franz Bronch. *Fermentforschung* 14, 115-17 (1933).--*dl*- $\alpha$ -Aminoheptylic acid was coupled with  $\text{BrCH}_2\text{COBr}$  to form bromoacetyl-*dl*- $\alpha$ -aminoheptylic acid, m. 74°, which was aminated to glycyl-*dl*- $\alpha$ -aminoheptylic acid, m. 245°. A similar coupling with  $\text{Me-CH(CH}_3\text{)-CHBrCOBr}$  gave *dl*- $\alpha$ -bromoisocaproyl-*dl*- $\alpha$ -aminoheptylic acid, m. p. not stated, which was aminated to *dl*-leucyl-*dl*- $\alpha$ -aminoheptylic acid, m. above 290°. Both peptides were completely resistant to erepsin and trypsin.

A. W. Dux

Further studies on the provocation of ereptic action in "erepsin-free" solutions prepared according to Waldschmidt-Leitz and Harteneck. V. Emil Abderhalden and Ella v. Ehrenwall. *Fermentforschung* 14, 118-27 (1933); cf. *C. A.* 27, 5758. --Erepsin-free trypsin acquires ereptic activity when heat-inactivated erepsin is added. The substance responsible for this effect is diffusible and thermostable. If the erepsin has been inactivated by  $\text{H}_2\text{S}$  it is no longer able to evoke ereptic activity in trypsin but regains this property on the addn. of L-3,4-dihydroxyphenylalanine.

A. W. Dux

Correction to the paper of Abderhalden and Zumstein on the behavior of polypeptides containing proline toward the erepsin and the trypsin-kinase complex. Emil Abderhalden. *Fermentforschung* 14, 128-9 (1933); cf. *C. A.* 25, 77. --The prepn. of glycyl-L-proline and *dl*-alaninyl-L-proline has been repeated and purer products have been obtained which are hydrolyzed by erepsin.

A. W. Dux

Addendum to the paper on the oxidation of lactic acid and of  $\beta$ -hydroxybutyric acid by the heart muscle. I. Banga, K. Laki and A. Szent-Györgyi. *Z. physiol. Chem.* 220, 278 (1933); cf. *C. A.* 27, 3227. --A repetition of the previous work gave neg. results, showing that the H-donor effect of the  $\text{MeCHOHCH}_2\text{CO}_2\text{H}$  used on that occasion was due to impurities.

A. W. Dux

Carboxylase. I. Wolfgang Langenbeck, Robert Juttemann, Otto Schaefer and Heinz Wrede. *Z. physiol.*

*Chem.* 221, 19 (1933). --The instability of carboxylase solns. during the process of purification can be overcome by adding 0.5 vol. of MeOH to lower the f. p. and operating at a temp. of  $-20^\circ$ . Addn. of MeOH to the yeast maceration juice ppts. the greater part of the proteins, leaving the carboxylase in soln. The remaining proteins are then pptd. by tannin and the excess tannin is removed by hide powder. Further purification is effected by adsorption on  $\text{Al}(\text{OH})_3$  and elution with  $\text{KH}_2\text{PO}_4$ . The best prepn. after dialysis was 1000 times as active in liberating  $\text{CO}_2$  from  $\text{AcCO}_2\text{H}$  as crude maceration juice contg. the same amt. of solids. The purification process removed sucrose, maltase and trypsin, and the product was protein-free.

A. W. Dux

Enzymes of the leucocytes. IX. The amylases of leucocytes. 2. Richard Willstätter and Margarete Rohdewald. *Z. physiol. Chem.* 221, 13-32 (1933); cf. *C. A.* 26, 1303, 4613. --Eight individual amylases are demonstrated: 4 lyo- and 4 desmo-amylases. The distinguishing features of the 4 members of each group are (1) inhibition by glycerol and independence of addnl. phosphate, (2) inhibition by glycerol and requirement of phosphate addn., (3) no inhibition by glycerol and independence of phosphate, (4) no inhibition by glycerol and requirement of phosphate addn. The differences are due to alterations of definite groupings rather than to an infinitely great no. of possible variations of a colloidal carrier. For the characteristic properties of these amylases 3 at. groupings of the mol. are considered responsible: the specifically active group, the group which renders the enzyme independent of phosphate, and the group which detrs. the inhibition by glycerol.

A. W. Dux

Phosphatides. VII. The sphingomyelins of heart muscle. F. Klenk. *Z. physiol. Chem.* 221, 67-72 (1933); cf. *C. A.* 27, 1311. --From 51 kg. of  $\text{Me}_2\text{CO}$ -dried beef hearts about 7 g. of a sphingomyelin prepn. was obtained which on hydrolysis by 0.5 N KOH in MeOH yielded lignoceric acid, stearic acid and sphingosine.

A. W. Dux

Emulsin. XII 1. The cleavage of phenol- $\beta$ -D-isorhamnoside by emulsin. B. Helferich, H. Rohr and E. Gunther. *Z. physiol. Chem.* 221, 90-2 (1933); cf. *C. A.* 27, 2959. Phenol- $\beta$ -D-isorhamnoside, m. 161.2°,  $[\alpha]_D^{20}$  80.8°, was obtained by hydrolysis of the tri-*Ac* deriv., m. 134.5°,  $[\alpha]_D^{20}$  in  $\text{CHCl}_3$  -7.3°, prepd. by Zn reduction of triacetyl-phenol- $\beta$ -D-glucoside-6-bromohydrin. It is hydrolyzed by almond emulsin about twice as rapidly as the corresponding glucoside. The activity of this enzyme is strictly parallel for the 2 substrates, in different stages of enzyme purification and damage by heat or ultra violet rays. There is no occasion to assume the existence of a specific isorhamnosidase. 2. The cleavage of  $\beta$ -D-glucuronides (conjugated glucuronic acids) by emulsin. B. Helferich and G. Sparnberg. *Ibid.* 92-4. --Hydrolysis of Na 1-menthol- $\beta$ -D-glucuronate by almond emulsin in different stages of purification does not parallel that of phenol- $\beta$ -D-glucoside or 1-menthol- $\beta$ -D-glucoside. A specific enzyme may therefore be assumed for the cleavage of glucuronides. 3. Impairment of emulsin by ultra-violet rays. B. Helferich and G. Brieger. *Ibid.* 94-8. --The relative rates at which enzymic activity toward 2 different substrates is destroyed by exposure of the enzyme prepn. to ultra-violet light are suggested as a means of detg. whether or not 2 specific enzymes are involved. The activity of almond emulsin toward phenol- $\beta$ -D-glucoside and phenol- $\beta$ -D-galactoside diminishes at the same rate; hence both substrates are hydrolyzed by the same enzyme. On the other hand, the activity toward phenol- $\beta$ -D-glucoside diminishes twice as rapidly as that toward phenol- $\alpha$ -D-mannoside, and the existence of 2 specific enzymes must be assumed. 4. The influence of formalin on the  $\beta$ -glucosidase and  $\beta$ -galactosidase action of emulsin. B. Helferich and S. Winkler. *Ibid.* 98-100. --The cleavage of methyl- $\beta$ -D-glucoside and phenol- $\beta$ -D-glucoside by almond emulsin occurs in the same ratio after the enzyme has been treated for varying lengths of time with  $\text{CH}_2\text{O}$ . The cleavage ratio, however, between these glucosides

and phenol- $\beta$ -D-galactoside is altered very considerably. This suggests the possible existence of a specific  $\beta$ -galactosidase.

**Emulsin.** XIII. Preparation and enzymic cleavage of glucosides of N-acetylglucosamine and of 2-deoxyglucose. Burkhardt, Helferich and Arndt Iloff. *Z. physiol. Chem.* 221, 252-8 (1933); cf. preceding abstr.—Tetraacetylphenol- $\beta$ -D-glucosaminide, m. 201.5-2.0°,  $[\alpha]_D^{25}$  -10°, was prepd. by acetylation of glucosamine with NaOAc and Ac<sub>2</sub>O and condensation with PhOH in the presence of p-McC<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>H, and hydrolyzed by NaOH to N-acetylphenol- $\beta$ -D-glucosaminide (I), m. 238° (decompn.),  $[\alpha]_D^{25}$  -5.4°. Triacetylphenol- $\alpha$ -D-glucoside-2-bromohydrin, m. 104.6°,  $[\alpha]_D^{25}$  60.7°, was obtained by bromination of triacetylglucal in AcOH and condensation with PhOH, then hydrolyzed by MeOH and a trace of MeONa to phenol- $\alpha$ -D-glucoside-2-bromohydrin, m. 122.4°,  $[\alpha]_D^{25}$  88.2°, and the latter reduced by Na-Hg to phenol-2-deoxy- $\alpha$ -D-glucoside (II), m. 162.3°,  $[\alpha]_D^{25}$  150°. The enzyme which hydrolyzes I is not identical with  $\beta$ -glucosidase since the ratio of the 2 activities is not const. for emulsin in different stages of purification, nor with  $\alpha$ -mannosidase since the activity ratio varies with different degrees of heat inactivation. The cleavage of II is not proportional to that of salicin by emulsin in different stages of purification, but is proportional to that of phenol- $\alpha$ -D-mannoside by emulsin in different degrees of heat inactivation.

**Cytochrome C.** Karl Zeile and Fritz Reuter. *Z. physiol. Chem.* 221, 101-16 (1933).—The cytochrome of yeast is a complex consisting of a hemin, a porphyrin and a colloidal carrier. By treatment with HBr-AcOH the porphyrin component was converted into hematoporphyrin which was obtained crvst. as the HCl salt and as free base and reduced by HCl-AcOH to mesoporphyrin. The porphyrin is therefore a deriv. of etioporphyrin III and contains the same side-chain grouping as the natural blood pigment. An attempt was made to det. the mol. wt. of the cytochrome system. On the basis of hemin content the smallest cytochrome unit would have a mol. wt. of 18,700, but the substance is actually a high mol. aggregate. The size of the aggregate as detd. by diffusion coeffs. varies with the  $p_H$ , the values for mol. wt. then being 185,000 at  $p_H$  5.6 and 89,500 at  $p_H$  9.0.

**Crystalline urinary urobilin, and further studies on stercobilin and copromesobiliviolin.** C. J. Watson. *Z. physiol. Chem.* 221, 145-55 (1933); cf. *C. A.* 26, 4070.—Methods are described by which urobilin was isolated in crvst. form from urine, and a sepn. of copromesobiliviolin and stercobilin effected from an AcOH-Et<sub>2</sub>O ext. of feces. Spectroscopic studies are reported, also reduction to the leuco compds. and prepn. of Cu salts.

**The protamines of some fish species.** M. A. Lisitzin and N. S. Aleksandrovskaya. *Z. physiol. Chem.* 221, 150-61 (1933).—Two protamines were prepd. from fish testes by Kossel's method: *percarine* from *Lucioperca sandra* (sulfate  $[\alpha]_D^{25}$  -67.4°,  $n_D^{20}$  1.3348, free base  $[\alpha]_D^{25}$  -55°,  $n_D^{20}$  1.3350) and *acipenserine* from sturgeon (sulfate  $[\alpha]_D^{25}$  15°,  $n_D^{20}$  1.3350). The former contains arginine and histidine but no lysine, the latter all 3 diamino acids. Both of these protamines combine with casein in the proportions 1:5 to form salts which are insol. in H<sub>2</sub>O and sol. in 10% NaCl, but sol. in alkalies and irreversibly coagulated by addn. of acid. The protamine caseinates may be salted out of soln. by (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, but are not coagulated by heat unless a Ca salt has been added.

**Cell-bound enzymes of tissues and glands.** III. Pancreatic amylase. Richard Willstätter and Margarete Rohdewald. *Z. physiol. Chem.* 221, 202-6 (1933); cf. *C. A.* 27, 3956.—The amylase of hog pancreas is almost completely sol. in 87 or 100% glycerol. Only a few thousandths percent of cell-bound or desmo-amylase are present. Although the lyo-amylase is readily extd. by either 87% or anhyd. glycerol, the anhyd. soln. in contrast to the other rapidly undergoes an irreversible inactivation. Glycerol itself has a slight inhibitory effect

on the enzyme which may be overlooked in pancreatic amylase because of its high concn. compared to that of leucocytes.

**Iron studies.** VIII. Differentiation of the easily cleavable blood iron from hemoglobin iron and from inorganic iron. Georg Barkan. *Z. physiol. Chem.* 221, 241-51 (1933); cf. *C. A.* 27, 2401.—Under suitable conditions of concn. of blood soln. and quantity of adsorbent the "easily cleavable" Fe may be distinguished from hemoglobin and inorg. Fe by its failure to be adsorbed on Al(OH)<sub>3</sub>. The sepn. thus effected disposes of the mutually contradictory views of Lintzel (*C. A.* 20, 213) and Starkenstein (*C. A.* 24, 3542) regarding the nature of this easily cleavable Fe of the blood.

**Influence of the underlying surface on the cataphoretic mobility of adsorbed proteins.** F. P. Bowden and A. Dunnett. *Physik. Z. Sowjetunion* 4, 340-5 (1933) (in English).—The cataphoretic behavior and apparent isoelec. points of oxy- and carbonyl-hemoglobin adsorbed onto quartz, charcoal, Cu, and paraffin oil dispersed in water, are dependent to a marked degree on the nature of the underlying surface. The hemoglobins differ in this respect from gelatin and albumin. Cf. Loeb, *C. A.* 17, 3682, and Freundlich and Abramson, *C. A.* 22, 3331.

**The mercury-reducing substances of normal urine.** B. Gwosdz. *Bull. soc. chim. biol.* 15, 900-81 (1933).—At least 30% of the Hg-reducing power of urine is due to a group of acids contg. N and unoxidized S, formed by the oxidation of protein ("oxy-proteic acids" of Bondzynski). These acids, together with the urinary pigments, were sepd. from the other Hg-reducing compds. of the urine as the mixed Ba salts. They account for a large proportion of the unknown Hg-reducing substances of Pénau and Taurat (*C. A.* 24, 5049). The effect of different protein diets on the excretion and S content of these substances was studied.

**Properties of the phosphorus-rich peptone obtained in the initial stages of tryptic digestion of casein.** P. Grabar. *Compt. rend. soc. biol.* 114, 13-15 (1933); cf. *C. A.* 27, 3726.—Casein yielded about 5% of a peptide contg. N 13.1% and P 2.2%. It formed an insol. Cu compd. The ratio of free amino N to total N was 1:14. Other properties are mentioned.

**Some chemical aspects of life. Food and evolution.** Jerome Alexander. *Scientia* 54, 252-63 (1933). Discussion.

**Norman Urquhart Meldrum (1907-1933).** E. G. H. Biochem. J. 27, 965-6 (1933).—Obituary notice. B. H.

**Mitogenetic radiation by means of a photoelectric counter tube.** Egon Lorenz. *U. S. Pub. Health Repts.* 48, 1311-18 (1933).—Biol. material tested consisted mainly of onion-base pulp and tips of onion roots. Mouse sarcoma 180, mouse embryo tissue and tetanized frog muscle were likewise tested. No mitogenetic radiation could be detected. The exptl. arrangement was of such intensity that it should have been possible to detect very weak intensities. The discrepancy between these expts. and those of others may perhaps be explained by static effects. When L. started his work, pos. effects were found. In all cases it could be shown that these were due to a static effect of the biol. material upon the field in the counter tube. Whenever tube and window were properly shielded against static influences, no pos. effect could be observed.

**Proteins.** XXIII. Fluctuation of the bioproteins (4). Kinsuke Kondo, Masashi Murayama and Hiromu Iwamae. *J. Chem. Soc. Japan* 54, 904-18 (1933); cf. *C. A.* 27, 5761.—The isoelec. point of wheat glutenins prepd. from the same variety of wheat varied from  $p_H$  5.00 to 5.80. This fluctuation can be minimized to  $p_H$  5.24-5.37 if the other factors of estn. are identical.

**Biochemical problems of nitrogen and the synthesis of proteins.** V. Kulikov. *J. Chem. Ind. (Moscow)* 1933, No. 6, 13-17.—Chem. reactions caused by bacteria are discussed with especial reference to protein synthesis.

H. M. Leicester

**The role of proteins in metabolism.** Wm. C. Rose. *Ohio J. Sci.* 33, 372-88 (1933).—The anabolism and metabolism of proteins and their possible relationship to adrenaline and thyroxine are reviewed. Particular attention is paid to the relative importance of individual amino acids composing ingested proteins. Present knowledge indicates that lysine, tryptophan, cystine or methionine, histidine and tyrosine or phenylalanine are indispensable.

I. M. Levine

**The optical rotatory power of heat-denatured egg albumin.** H. Albert Barker. *J. Biol. Chem.* 103, 1-12 (1933). The rotatory power of alk., heat-denatured egg albumin varies in an orderly manner with the time and temp. of heating and approaches a definite limiting value which is primarily a function of the H-ion and protein concns. of the soln. during the actual heating. The optical rotatory power is the only property which at present is known to be suitable for quant. characterizing a denatured protein and one may assume that samples of denatured egg albumin (or other proteins) having the same  $[\alpha]$  are probably identical, whereas those samples possessing markedly different values are certainly distinct chem. entities.

A. P. Lothrop

**Radium emanation and muscle imbibition.** P. Mascherpa and A. Sgro. *Boll. soc. ital. biol. sper.* 8, 479-84 (1933).—Small doses of emanation produce an increase in muscle imbibition during the first 8 hrs. Later, because of changes in the permeability of the muscle membrane, there is a rapid flow of substances from the muscle into the water with a consequent decrease in the wt. of the muscle. There is also an initial increase in elec. cond. of the radioactive water compared with the controls. Large doses of emanation produce from the start a decrease in the wt. of the muscles compared with the controls. The sec. cond. of the water in which the controls are immersed is always greater than that of the radioactive water.

Peter Masucci

**Thoughts and proposals on the nomenclature, classification and quantitative valuation of accessory factors modifying enzymic reactions.** Camillo Artom. *Boll. soc. ital. biol. sper.* 8, 481-8 (1933).—A scheme of classifications including the use of symbols, based essentially on the mechanism of enzyme action.

Peter Masucci

**The esterase of enteric juice.** Lorio Reale. *Boll. soc. ital. biol. sper.* 8, 492-7 (1933); cf. *C. A.* 27, 2195. Thymol, toluene and  $\text{CHCl}_3$  in satd. soln. and 1 hr. in contact with the juice showed inactivations as follows: thymol 8; PhMe 27;  $\text{CHCl}_3$  34%. Enteric juice was very resistant to quinine and atovyl; 0.5 g quinine and 0.25 g. atovyl per l. inactivated the enzyme only 18-20%. Bile, bile salts and Na oleate inhibited the action of the enzyme very markedly (8-70%). Albumin had little influence; glycerol none. Both in an acid and alk. reaction, Willstätter's accelerating system inhibited the action of the enteric esterase. A concn of 0.02 M Na veronal at  $\text{pH}$  7.3 inactivated the esterase (33%).

Peter Masucci

**The viscosity of the blood following the introduction of suspensions and anticoagulants.** Luigi Robuschi. *Boll. soc. ital. biol. sper.* 8, 550-4 (1933). **Variations in the viscosity of the blood after the introduction of suspensions and anticoagulants.** *Ibid.* 555-60. **The action of heat on the viscosity of the plasma and serum.** *Ibid.* 560-4. **The physical state of proteins and plasma and their viscosity in relation to anticoagulants.** *Ibid.* 564-9. The intravenous injection of 8 cc. of a 1.25% soln. of neohirudin per kg. of rabbit slightly increases the viscosity of the plasma. The intravenous injection of 20 cc. of a 5% suspension of India ink per kg. of rabbit markedly decreases the viscosity of the plasma. The injection of the anticoagulant and the suspension does not change the viscosity of the plasma. Heating normal plasma and the plasma contg. the suspension to 60° decreases the viscosity, but heating serum to 60° increases the viscosity; the decrease is marked for plasma contg. the anticoagulant plus the suspension, slight for the normal and that contg. the suspension alone. The effect of diln. on viscosity is much more regular in the anticoagulant plasma +

suspension than in the others. The results are explained by assuming certain changes in the phys. state of the plasma proteins.

Peter Masucci

**The  $\text{pH}$  in electrolytic chromophoresis. Fibrillar formations in the nerve cells.** Giovanni Palma. *Boll. soc. ital. sper.* 8, 591-4 (1933).

Peter Masucci

**The influence of radium emanation on the electric conductivity of egg albumin.** P. Mascherpa. *Boll. soc. ital. biol. sper.* 8, 617-20 (1933).—The elec. cond. of egg albumin solns. is increased by Ra emanation. The increase is proportional to the quantity of emanation used. The elec. cond. at the end of 24 hrs. was: (1) egg albumin in water + Ra emanation (of 509.85 Mache U.)  $0.1185 \times 10^{-4}$ ; in water +  $\text{H}_2$  gas  $0.1000 \times 10^{-4}$ ; (2) in water + 988.80 Mache U.  $0.2486 \times 10^{-4}$ ; in water +  $\text{H}_2$  gas  $0.1585 \times 10^{-4}$ ; (3) in water + 1585.17 Mache U.  $5.1826 \times 10^{-4}$ ; in water +  $\text{H}_2$  gas  $1.3176 \times 10^{-4}$ . With very high doses of Ra emanation as in (3) the protein soln. very rapidly became turbid.

Peter Masucci

**Influence of the coagulation of proteins on the activity of amylase.** A. Oparin, S. Manskaja and M. Magaram. *Biochem. Z.* 265, 21-8 (1933).—The thermolability of amylase is increased by addn. of undialyzed egg albumin but diminished by addn. of dialyzed albumin. Amylase may be inactivated also in the cold in an acid medium. At  $\text{pH}$  6.1 dialyzed, boiled albumin soln. added to the amylase can be pptd. without adsorbing any of the enzyme, but at lower  $\text{pH}$  the pptn. in the cold is accompanied by considerable loss of activity. Peptone can protect amylase against inactivation in the cold but cannot reverse the process if the inactivation has already occurred. However, a considerable portion of the amylase inactivated by the albumin pptn. either by heat or by cold can be reactivated by digesting the protein ppt. with pepsin.

S. Morgulis

**Changes in the elimination of zinc under the influence of radiation.** Kyuhci Nakadate. *Biochem. Z.* 265, 61-3 (1933). Animals were radiated with a variety of lamps but under such conditions that during the 5 min exposure the radiation dose was 20.4 cal. In every instance an increase in the Zn content of tissues was found in the radiated animals showing that its elimination was diminished. The effect of ultra-violet rays was less than that of the longer wave lengths.

S. Morgulis

**Changes in metabolism under the influence of radiation XII Effect of different kinds of radiation on the glutathione content of the organs of radiated animals.** Ludwig Pincussen and S. Takahashi. *Biochem. Z.* 265, 64-8 (1933); cf. *C. A.* 26, 1026; 27, 4836.—The effect of radiation with different parts of the visible, ultra-violet and ultra-red spectra was detd. on the glutathione content of liver, spleen, lung and muscle.

S. M.

**Changes in the pyrophosphate fraction (adenosinetric phosphoric acid and free pyrophosphate) in muscle.** O. Reinschmidt and M. Emitrenko. *Biochem. Z.* 265, 69-75 (1933).—A pentose compd. partly precipitable by Ba appears in the  $\text{CCl}_3\text{CO}_2\text{H}$  ext. from muscle which has been ground in water. At the same time there is a diminution in the pyrophosphate fraction, principally the free pyrophosphate. When muscle is ground in  $\text{CCl}_3\text{CO}_2\text{H}$  there is likewise formation of a pentose compd. but not so great. In autolyzed muscle pulp the pyrophosphate fraction decreases, but since the increase in orthophosphate exceeds this, other phosphate compds. must be involved. On thawing out ground muscle which has been frozen by liquid air, both free and bound pyrophosphate undergo considerable decompn., but the increase in orthophosphate is less than that expected. Apparently an org. P compd. is formed.

S. Morgulis

**Oxidative inhibition of glycolysis and the mechanism of the Pasteur reaction.** Fritz Lipmann. *Biochem. Z.* 265, 133-40 (1933).—Oxidizing reagents ( $\text{I}_2$ , quinone) in small concn. inhibit glycolysis. This is not due to an oxidation of glutathione, because muscle exts. free from SH glycolyze normally, but to an oxidation of the glycolytic enzyme. 2,6-Dichlorophenol-indophenol in proper concn. can reproduce the Pasteur reaction in

muscle ext. Although the glycolysis in muscle ext. is independent of the presence of  $O_2$ , in the presence of the dye, which is reduced in  $N_2$  but oxidized in  $O_2$ , glycolysis is nearly completely inhibited only in  $O_2$ , the inhibition by the dye +  $O_2$  being reversible. In the  $O_2$ -sated cells the inhibition of glycolysis is likewise due to a reversible oxidative inactivation of the glucolytic enzyme system.

S. Morgulis

**Coenzyme activity. VI. The constitution of adenosinetriphosphoric acid.** H. K. Barrenscheen, Karl Braun and Wilhelm Filz. *Biochem. Z.* 265, 141-7 (1933); cf. *C. A.* 27, 112.—Evidence is presented which throws doubt on Lohmann's hypothesis of the inosinepyrophosphoric acid nature of coenzyme. Until evidence to the contrary is forthcoming the constitutional formula for adenosinetriphosphoric acid, with the 2 pyrophosphate groups in an imino linkage with the  $NH_2$  of the adenine should be retained.

S. Morgulis

**The theory of glycolysis.** H. K. Barrenscheen and Hela Beneschovsky. *Biochem. Z.* 265, 159-68 (1933).—According to Nilsson hexosemonophosphate undergoes physiol. decompn. into glyceraldehyde phosphate and a 3-C substance, possibly  $AcCHO$ . According to Embden, on the contrary, hexosediphosphate is the intermediate product which splits into a mol. of glyceraldehyde phosphate and  $OC(CH_2OH)_2$ , which through a Cannizzaro reaction change to phosphoglyceric acid and glycerophosphoric acid, the latter giving rise to lactic acid through the intermediate step of  $AcCO_2H$ . According to Embden  $AcCHO$  plays no part as intermediate substance in glycolysis. Expts. with phosphoglyceric acid show that muscle and, to a slight extent also, liver tissue convert this to  $AcCO_2H$ , leading also to a small increase in lactic acid. Glyceraldehyde phosphate, however, is utilized by all tissues, and in the glycolysis of muscle it gives lactic acid, but when the glycolytic process is suppressed  $AcCHO$  is formed instead. However, only a small portion of the glyceraldehyde phosphate is thus transformed, the largest amt. serving as a step in the formation of hexosediphosphate. The authors, therefore, accept Nilsson's view that the first product in the decompn. into 3-C substances is the appearance of a glyceraldehyde phosphate. Normally, the decompn. would proceed from this to lactic acid through  $AcCHO$  and  $AcCO_2H$ . The formation of phosphoglyceric and of glycerophosphoric acids is a phenomenon of stabilization, as is also that of hexosediphosphate.

S. Morgulis

**Transformation of acetoacetaldehyde by yeast.** Stefan Grzycki. *Biochem. Z.* 265, 195-8 (1933).—Acetoacetic acid is reduced by fermenting yeast to  $d$ - $\beta$ -hydroxybutyric acid. Although the Na salt of  $AcCH_2CHO$  reacts alk. when added to the fermenting sugar, the alk. is neutralized by the evolved  $CO_2$ . The  $AcCH_2CHO$  is reduced to  $d$ - $\beta$ -butylenglycol.

S. Morgulis

**Influence of fluoride on phosphatase activity.** Ernst Auhagen and Stefan Grzycki. *Biochem. Z.* 265, 217-22 (1933).—Kidney phosphatase is unaffected by NaF but yeast phosphatases are very sensitive to this inhibitor. The effect of NaF on taka-glycerophosphatase depends upon the  $pH$ , but not on the alk. A slight inhibition appears on the acid side.

S. Morgulis

**The partial enzymes of myrosinase.** Carl Neuberg and Otto von Schoenebeck. *Biochem. Z.* 265, 223-38 (1933).—See *C. A.* 27, 4823.

S. Morgulis

**Mechanism of enzyme action. XI. Cryolysis, and gas absorption of lyophilic colloids.** 1. Gertrud Weiss and F. F. Nord. *Z. physik. Chem.* A166, 1-15 (1933); cf. *C. A.* 26, 2908.—Besides the cryoscopic expt. previously described (*C. A.* 26, 2103), the absorption of  $C_2H_4$ ,  $C_2H_2$ , and  $N_2O$  on Na oleate, egg albumin, and gelatin was investigated before and after freezing at  $18^\circ$  and  $-79^\circ$ .

G. M. Murphy

**Biological effects of extreme pressures. Action of high pressures on proteins.** J. Bassot, M. Machebeuf and G. Sandor. *Compt. rend.* 197, 796-8 (1933); cf. *C. A.* 27, 3493.—Horse serum was subjected to pressures varying from 3000 to 13,000 atms. for periods up to 30 min.

1 Min. pressure for gelification was 13,000<sup>a</sup> atms. Serum globulin jelled completely at 15,000 while serum albumin remained limpid at all pressures up to 15,000 atms. Studies are being made to det. whether pressure affects the antigenic specificity of proteins.

## B- METHODS AND APPARATUS

STANLEY R. BENEDICT

**A simple method for determining the calcium and phosphorus contents of feces.** A. Lichtenstein. *Nederland. Tijdschr. Geneeskunde* 77, 4336-9 (1933).—Finely grind and mix the feces; weigh 1 g. in a crucible and ash at a temp. not exceeding  $400^\circ$ . Dissolve the ash in dil.  $HNO_3$ . To sep. P, add 4 cc. of a 15% soln. of  $NH_4$  molybdate. Remove the ppt. by centrifuging; one may dissolve it in NaOH to det. P; it is free from Ca. To the supernatant fluid, contg. all the Ca, add NaOH and then  $AcH$ , and ppt. Ca by Na oxalate. Dissolve the pptd. Ca oxalate in  $H_2SO_4$  and titrate with permanganate.

R. Beutner

**Traces of blood in the feces.** L. A. Hulst. *Nederland. Tijdschr. Geneeskunde* 77, 4455-9 (1933).—II. detects blood in the feces of healthy subjects who were on a milk diet, by the benzidine reaction as follows: dissolve 100 mg. benzidine in 8 cc.  $AcH$  and add 2 cc. 3%  $H_2O_2$ . Introduce a lump of feces into this mixture; a greenish or bluish color indicates a pos. reaction. The reaction was, however, neg. and remained so even when a food rich in peroxidases—like beans—was given. For the detection of blood in the feces, it is sufficient, therefore, to prescribe a bloodless diet, and to see that there are no bleeding spots in the nose or throat.

R. Beutner

**A new pycnometer for the calibration of respiration apparatus with alcohol.** Alexander Szakál. *Arbeitsphysiol.* 6, 235-8 (1932).

T. M. Carpenter

**A new method of determining the free water of erythrocytes.** A. Slawinski. *Bull. soc. chim. biol.* 15, 982-91 (1933); cf. *C. A.* 27, 3732.—The free water of the corpuscles is detd. by comparing the relative elec. cond. of 2 samples of blood to which different proportions of Na citrate have been added, and applying the math. formula given. Horse corpuscles contain 51% free water.

L. E. Gilson

**A method for the purification of botulinus toxin.** Shigeru Tani. *Compt. rend. soc. biol.* 114, 237-9 (1933).

L. E. Gilson

**Microdetermination of residual nitrogen and urea in the blood.** Friedrich Rappaport. *Mikrochemie* 14, 49-80 (1933); cf. *C. A.* 27, 5357.—A description of expts. on the applicability of the hypobromite method for the iodometric detn. of  $NH_3$ , of methods for detg. the residual N in blood and in serum and methods for detg. urea in serum and in blood. The analyses were made with 0.2 cc. samples. The hypobromite method consists in treating the sample with  $Br_2$  in a suitably buffered soln., allowing it to stand a few min., adding KI and acid and titrating with  $Na_2S_2O_3$ . In carrying out the method with small quantities of materials it is necessary to take particular precautions with respect to both reagents and procedure.

W. T. H.

**Microdetermination of indican in the blood.** F. Rappaport and H. Engelberg. *Mikrochemie* 14, 74-80 (1933).—By modifying the app. and taking special precautions, it has been found possible to carry out the condensation with thymol or bromothymol and satisfactorily det. the indican content of 0.2 cc. of blood serum or urea.

W. T. H.

**The determination of glycogen.** Melville Sahyun. *J. Biol. Chem.* 103, 203-8 (1933); cf. *C. A.* 26, 751. When charcoal is used to measure complete pptn. of glyco-

gen, not more than 50 mg. should be added as larger amts. (cf. C. A. 27, 2971, 3496) interfere with the subsequent hydrolysis. A small quantity of 20-30 mg. can be easily estd. on the tip of a spatula without weighing. Glycogen is hydrolyzed in 20 min. in 5 N  $\text{H}_2\text{SO}_4$  but the vol. of acid should be kept as small as possible to minimize the quantity of  $\text{Na}_2\text{SO}_4$  formed on neutralization.

A. P. Lothrop

**An apparatus for automatically measuring the respiratory exchange of small animals.** Helen G. Lewis and James M. Luck. *J. Biol. Chem.* 103, 209 (1933). - In the closed-circuit type of app. described for measuring the respiratory exchange of small animals the rate of  $\text{O}_2$  consumption is detd. electrically by the rate at which  $\text{H}_2\text{O}$  must be admitted to maintain a const. pressure in the system and the  $\text{CO}_2$  production by the change in conductivity, automatically recorded, of an absorbing soln. of  $\text{Ba}(\text{OH})_2$ . The basal metabolic rate of male rats, fasted 36 hrs., of 220 g. body wt., and at an environmental temp. of  $28^\circ$ , averaged 744 cal. per day per sq. m. of body surface.

A. P. Lothrop

**A simple photoelectric colorimeter.** G. A. Millikan. *J. Physiol.* 79, 152 (1933). - A colorimeter using a differential Cu-CuO photoelec. cell and color filters is described. It is especially well suited for measuring the degree of oxygenation of hemoglobin solns.

J. F. L.

**A selective staining method for certain fats.** Vincenzo Magri. *Boll. soc. ital. biol. sper.* 8, 569 (1933). - For histological sections the technic is: (1) Fixation in  $\text{HCOH}$ . (2) Sectioning (frozen). (3) Staining for 10 min. in a mixt. of equal parts of freshly prepd. soln. (A) and (B). (A) Heat to boiling 1 g.  $\alpha$ -naphthol in 100 cc. distd. water and add dropwise 0.1 N  $\text{NaOH}$  until the  $\alpha$ -naphthol is completely dissolved. Cool. (B) A 1% aq. soln. of dimethyl-*p*-phenylenediamine. Mix (A) and (B) in equal parts and alkalize strongly. (5) Inclusion in Apathy gum syrup. The fatty drops contg. neutral non-satd. fats appear a bright violet, the oxidase granules a blue and the remainder of the field a yellowish green color. The pos. violet reaction is only given by the glycerides of non-satd. fatty acids.

Peter Masucci

**The nuclear reaction of Feulgen on platelets.** Augusto Corradetti. *Boll. soc. ital. biol. sper.* 8, 603 (1933). Feulgen's test was neg. for blood platelets. These results do not prove conclusively that thymus nucleic acid is absent but may be present in amts. too small to be detected by the test.

Peter Masucci

**The behavior of the specific granulations of white blood corpuscles and bone marrow cells after immersion in a normal solution of hydrochloric acid.** Augusto Corradetti. *Boll. soc. ital. biol. sper.* 8, 606 (1933). Blood and bone marrow smears were treated with Giemsa stain, fixed in 95% alc. and immersed 4 min. in N HCl at  $60^\circ$ . Examn. showed that only the eosinophile and azurophile granulations of the platelets and megakaryocytes remained unchanged.

Peter Masucci

**The behavior of platelets and megakaryocytes after prolonged immersion in normal hydrochloric acid.** Augusto Corradetti. *Boll. soc. ital. biol. sper.* 8, 607 (1933). - Blood and bone marrow smears (newborn human and cat) were fixed in 95% alc. for 24-48 hrs., immersed in N HCl for 45-60 min. at  $60^\circ$  and treated with Giemsa stain for 45-60 min. Examn. reveals that the platelets remain unaltered; their azurophile granules are as colored as normal platelets. Likewise the azurophile granulations of the megakaryocytes of the bone marrow cells remain unaltered.

Peter Masucci

**Analytical studies. XVII. Microdetermination of lead and zinc in organic material.** Ludwig Pincussen and Ernst Brück. *Biochem. Z.* 265, 58 (1933); cf. C. A. 25, 2751; 27, 744. - For the Pb detn. the following reagents are required: Fe-free  $\text{HNO}_3$ , Pb-free  $\text{H}_2\text{SO}_4$  (1:1), perhydrol, 70%  $\text{AcONH}_4$ , 10%  $\text{Na}_2\text{S}$ , gum arabic soln. 1:10, a standard soln. contg. 1 mg. Pb per cc. (made by dissolving 1.6 g.  $\text{Pb}(\text{NO}_3)_2$  ground and dried at  $100^\circ$  in a l. of  $\text{H}_2\text{O}$ ). Procedure: Cover 2 g. dry tissue in a 50 cc. Kjeldahl flask with 2-3 cc.  $\text{H}_2\text{SO}_4$ . Add, drop by drop,

1  $\text{HNO}_3$ , as long as there is any reaction; leave overnight, heat cautiously, add 1 cc. perhydrol until a colorless soln. is obtained. Transfer the ash soln. quantitatively to a centrifuge tube, dil. to about 25 cc. with  $\text{H}_2\text{O}$  and centrifuge, preferably the next day. Wash the residue with a couple of cc. 1%  $\text{H}_2\text{SO}_4$ , then add to it 2 cc.  $\text{AcONH}_4$  soln. and place in a boiling bath for 10 min. Centrifuge and pour off the clear soln. into a 25 cc. flask. Digest the undissolved residue in the same manner 4-5 times, then once with  $\text{H}_2\text{O}$ , and finally dil. the contents of the flask to vol. Prep. a standard with 0.2-0.5 mg. Pb, with the same quantity of  $\text{AcONH}_4$ , and dil. to 25 cc. Add a drop or 2 of  $\text{Na}_2\text{S}$ , and 1 cc. gum arabic to each flask and match the colors at once. The method is sensitive to 0.1 mg. Pb. For the Zn detn. addnl. reagents are required: satd.  $\text{H}_2\text{S}$  soln., 30%  $\text{NaOH}$ , concd.  $\text{AcOH}$ , N HCl, 15%  $\text{AcONH}_4$ , dil. HCl (1 pt. acid + 1.5 pt.  $\text{H}_2\text{O}$ ). Make the standard soln. contg. 1 mg. Zn per cc. by dissolving in 1 l. either 6.79 g.  $\text{K}_2\text{SO}_4 \cdot \text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$  or 4.4 g.  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ . Transfer quantitatively the tissue ash prepd. as before to a quartz dish, evap. to dryness and drive off the excess  $\text{H}_2\text{SO}_4$ . Dissolve the residue in 5 cc. dil. HCl, transfer with plenty of  $\text{H}_2\text{O}$  to a 25 cc. centrifuge tube, centrifuge, and wash the residue with dil. acid and water. Place the combined wash fluids in a 50 cc. Erlenmeyer flask, warm on the water bath, pass in  $\text{H}_2\text{S}$ , stopper and leave overnight. Addn. of a little ether facilitates the pptn. of sulfides; filter them through a hardened paper and wash with satd.  $\text{H}_2\text{S}$  soln. Free the filtrate from  $\text{H}_2\text{S}$ . To free it from Fe add 6 drops  $\text{HNO}_3$ , transfer quantitatively to a 25 cc. centrifuge tube, make alk. with 30%  $\text{NaOH}$ , then acidify with  $\text{AcOH}$  and centrifuge off the ppt. Dissolve the residue in a little dil. HCl, and repeat the treatment with  $\text{NaOH}$  and  $\text{AcOH}$  until a red-brown ppt. is produced. Unite the supernatant fluids in a 50 cc. flask and treat with  $\text{H}_2\text{S}$ . Leave the stoppered flask overnight. Collect the pptd.  $\text{ZnS}$  on a hardened paper, wash with  $\text{H}_2\text{S}$  water acidified with  $\text{AcOH}$ , and ash. Free the ash from further Fe impurities by treating it with 2 cc.  $\text{AcOH}$  in a centrifuge tube and wash repeatedly with acidified  $\text{H}_2\text{O}$ . Use the combined solns. obtained from centrifuging for the nephelometric detn. Use measuring cylinders, 15 or 25 cc., contg. 5 cc.  $\text{H}_2\text{S}$ -water, 1 cc. N HCl and 2 cc.  $\text{AcOH}$ . Add the unknown soln. or an aliquot and the standard soln., then 2 cc.  $\text{AcONH}_4$ , make up both to the same vol., mix and compare in a nephelometer after 15 min. The method is sensitive to 0.03 mg. in 15 cc. S. M.

**Colorimetric determination of calcium as picrolonate.** F. Alten, H. Weiland and E. Knippenberg. *Biochem. Z.* 265, 85 (1933). With 5 cc. of a soln. contg. 0.020-0.150 mg. Ca per cc., neutralize the acidity with 2 N  $\text{NaOH}$  to methyl orange, add a few drops 10% sulfosalicylic acid, dil. to 10 cc. and filter. Place 1-2 cc. of the filtrate in a small centrifuge tube, add 3 vols. of ice-cold 0.01 N picrolonic acid soln. (made by dissolving 2.64 g. in a l.  $\text{H}_2\text{O}$ , warming on the water bath and filtering the next day), and leave in a cold place for 4 hrs. with occasional shaking. Free the silny ppt. from the supernatant liquid by drawing off the latter with the aid of a porcelain filtration rod, washing out the traces of picrolonic acid with small quantities of anhyd. ether. Wash the ppt. and rod with hot water and transfer the soln. of Ca picrolonate to a 50 cc. flask. Heat this on a water bath for 10 min. with 1 cc. satd.  $\text{Br}_2$  water, add 10 cc. alc., cool, and make alk. with 2 cc. 2 N  $\text{NaOH}$ . Keep the colored soln. overnight in a protected place and exam. with the step colorimeter, using the 530 m $\mu$  filter. Mg, K, Na and  $\text{NH}_4$  do not interfere with the detn. S. M.

**Colorimetric determination of phosphoric acid in the presence of arsenate ions. Contribution to the study of induced reactions.** H. K. Barrenscheen, J. Banga and K. Braun. *Biochem. Z.* 265, 148-53 (1933). - A re-exam. of the problem of the colorimetric detn. of P in the presence of arsenate ions by the procedure recommended by Braunstein shows that this completely fails to yield reproducible results. Also, the variation in the result depending upon the relation between the phosphate

and arsenate concns. makes the application of a correction impossible. It was found that this detn. demonstrates Skrabal's induced reactions, the abs. and relative error of the analysis increasing as the abs. or relative concn. of As in the system increases. Attempts to avoid this by means of  $\text{NaHSO}_4$  to reduce the arsenate to arsenite which would not interfere with the reaction of phosphate with the molybdate have not yielded the desired result.

S. Morgulis

**Report on (the determination of) enzymes.** A. K. BALKS. *J. Assoc. Official Agr. Chem.* 16, 479-80 (1933); cf. *C. A.* 26, 5514.—The previously described method will be studied collaboratively. A. Papineau-Couture

**Methods of determining cholesterol. II. Volumetric and gravimetric methods.** A. Santos Ruiz and Isabel Torres. *Anales soc. españ. fis. quim.* 31, 685-94 (1933); cf. *C. A.* 27, 3064.—The volumetric method of Okey (*C. A.* 24, 5780), and as modified by Turner (*C. A.* 25, 6657), and the gravimetric method of Szent-György (*C. A.* 17, 3197), for detn. of cholesterol in normal human serum, were tested. The Okey method, as modified by Turner, is best for detg. plants exts., where a colorimetric method cannot be used. Recovery is 106.6%. The volumetric method of Bang (Micométodos de Pincussen, 1932) is only recommended for simultaneous detns. of neutral fats. Recovery is only 65.8 mg. %. The Szent-György method is best; recovery is 100.2%.

E. M. Symmes

**Local detection and determination of chlorophyll in plant tissues.** S. Ilupert, H. Hofmeier and K. Heidrich. *Ber. Dtsch. Bot. Ges.* 51 (1933), cf. *C. A.* 26, 756.—The green color which develops when chlorophyll-poor plant tissue is treated with  $\text{H}_2\text{SO}_4$  and a Cu salt can be used for detn. of the chlorophyll. For a quant. method, 0.1-0.3 g. of plant material is treated with the reagent, filtered and washed, dried at 50°, and freed from yellow pigment by extn. with 40%  $\text{Me}_2\text{CO}$ . The Cu compd. (probably Cu phaeophytin) is then dissolved in abs.  $\text{Me}_2\text{CO}$  and the absorption of 30 mm thickness of the soln. compared with that of a standard. The absorption of the Cu compd. is about 30% higher than that of K chlorophyllin prepd. by Wiltstätter's method.

## C - BACTERIOLOGY

CHARLES B. MORREY

**Bactericidal power of sodium ricinoleate.** H. Violle. *Compt. rend.* 197, 714-16 (1933). The effect of a 1:1000 soln. of Na ricinoleate on many kinds of bacteria was studied. The common and pathogenic bacteria of the intestinal tract were unaffected. *Streptococci* sp. were killed but *staphylococci* were not.

L. E. Gilson

**Variations in the bactericidal power of gold salts on Koch's bacillus in vitro depending upon the composition of the medium and the number of bacilli introduced.** Paul Courmont, Henri Gardère and P. Pichat. *Compt. rend. soc. biol.* 114, 48-9 (1933); cf. *C. A.* 27, 322.—Relation between the bactericidal action of gold salts on Koch's bacillus in vitro to that in vivo. *Ibid.* 50 1.—Some addnl. expts. with saucocrysin and allocrysin are reported.

L. E. Gilson

**The extraction of a toxic and antigenic complex from Aerttrycke's bacillus.** André Boivin, Ion Mesrobianu and Lydia Mesrobianu. *Compt. rend. soc. biol.* 114, 307-10 (1933).

L. E. Gilson

**Comparison of the enumeration of bacteria by means of solid and liquid media.** C. T. Butterfield. *U. S. Pub. Health Repts.* 48, 1292-7 (1933).—Under the standardized conditions of these tests, the plate colony counts and the most probable nos. computed from the diln. method are in excellent agreement for the detn. of *Es. coli*, and are in fair agreement for *Aerobacter aerogenes*.

J. A. Kennedy

The chemistry of the lipides of tubercle bacilli. XXXV.

**The constitution of phthiocol, the pigment isolated from the human tubercle bacillus.** R. J. Anderson and M. S. Newman. *J. Biol. Chem.* 103, 197-201 (1933); cf. *C. A.* 27, 5364.—The yellow cryst. pigment, phthiocol, isolated from the  $\text{Me}_2\text{CO}$ -sol. fat of the human tubercle bacillus, has been identified as 2-methyl-3-hydroxy-1,4-naphthoquinone. This formula has been confirmed by synthesis.

A. P. Lothrop

**The formation of oxalic acid in *Mycobacterium tuberculosis* microcultures.** M. Bergonzini. *Boll. soc. ital. biol. sper.* 8, 527-8 (1933).—Using Fortner's technic, B. observed crystals of Ca oxalate in 10-15-day-old cultures of *M. tuberculosis*. Similar crystals were observed in cultures of *Aspergillus*, *Penicillium* and *Streptothrix*, but not in cultures of coli, dysentery, cholera or staphylococcus groups.

Peter Masucci

**The dehydrogenase activity of *Es. coli communis* on higher fatty acids.** F. P. Mazza and A. Cimmino. *Boll. soc. ital. biol. sper.* 8, 531-4 (1933).—In the presence of a buffered suspension of *Es. coli*, the higher fatty acids undergo a rapid oxidation; the oxidation does not take place if the bacteria are killed by heat at 100°. The velocity of dehydrogenation is: stearate > oleate > palmitate. During the first 50-60 min. oxidation occurs without production of  $\text{CO}_2$ .

Peter Masucci

**The mechanism of activation of glucose in lactic acid fermentation. II. Cl. Pronageot and J. Roux. *Biochem. Z.* 265, 13-20 (1933); cf. *C. A.* 26, 2209.—Expts. with variable amts. of bacteria (on the basis of dry wt.) show that the velocity of the reaction is proportional to the quantity of bacteria. The rise in the curve of  $\text{CO}_2$  production for a given quantity of bacteria is practically the same with a range of glucose concns. from 0.052 to 2.6%. But the induction, which is unaffected when the glucose concn. varies from 1 to 0.1, becomes considerably greater as the concn. diminishes to 0.04 and 0.02.**

S. Morgulis

**Respiration and fermentation of lactic acid bacteria.** John G. Davis. *Biochem. Z.* 265, 90-104 (1933).—*L. delbrueckii* produces  $\text{H}_2\text{O}_2$  equiv. to the amt. of  $\text{O}_2$  used in the oxidation of the substrate. Methylene blue or *p*-phenylenediamine, which increase the rate of oxidation 100-300%, diminishes the formation of  $\text{H}_2\text{O}_2$  about 25%, thus causing the respiratory quotient to rise. The increase in respiration by methylene blue is due to the oxidation of lactic acid, and is unaffected by poisoning with  $\text{CH}_3\text{CO}_2\text{H}$ , while the oxidation of sugar is inhibited either in the presence or absence of methylene blue. The glucolysis is thus an essential step in the respiration. This is little affected by HCN, but the respiration of a different strain of organisms (*B. cereale*) is suppressed by HCN or  $\text{CO}$ , and no  $\text{H}_2\text{O}_2$  is produced in their oxidative process nor is it influenced by methylene blue. Their respiration is accord. with fermentation, and the pyruvic acid formed is changed partly to  $\text{AcOH}$ , acetoin and alc.

S. Morgulis

Alkyl derivs. of halogen phenols and their bactericidal action (Klarman, et al.) 10.

**Gershensfeld, Louis.** Bacteriology and Sanitary Science for Students in Pharmacy, Chemistry and Allied Sciences. 2nd ed., revised. Philadelphia: Lea & Febiger. 493 pp.

## D - BOTANY

THOMAS G. PHILLIPS

**Physicochemical aspects of sex plants.** W. F. Lockwing. *Proc. Soc. Exptl. Biol. Med.* 30, 1215-20 (1933).—Staminate plants of photoperiodic, long-day spinach and short-day hemp were richer in Fe, Mg, sugar, sol. sap constituents and oxidative activity of tissue fluids than the corresponding pistillate plants. The findings reflect the rapid metabolism necessary for the production of large amts. of pollen, which comprise 10-15% of the dry wt. of the tops.

C. V. Bailey

**The latex of the Jac tree of Cambodia.** Gabriel Bertrand and Georges Brooks. *Compt. rend.* 197, 661-5

(1933).—Cambodge lac, the latex of *Melanorrhoea laccifera*, family Anacardiaceae, was treated with EtOH. A gum contg. laccase was pptd. From the EtOH soln. a new phenol, moreacol (I), somewhat similar to laccol, was sepd. The yield of crude I was 55-80% of the latex. I was readily oxidized by the air to a brown resin. I,  $C_{12}H_8(OH)_2C_{17}H_{31}$  or perhaps  $MeC_{11}H_7(OH)_2C_{16}H_{30}$ , purified by vacuum distn, m. 28°,  $d_{15} = 0.9874$ ,  $n_{20} = 1.5277$ ; I diacetate, liquid,  $d_{20} = 0.9957$ ,  $n_{20} = 1.4958$ . Tetrahydromoreacol, prepd. by hydrogenation of I, m. 95.3°; its diacetate m. 70.5°.

**Assimilation of sulfates by fungi. Euthiotrophy and parathiotrophy.** Michel Volkonsky. *Compt. rend.* 197, 712-14 (1933); cf. *C. A.* 26, 3541.—Not one of the many species from 5 genera of Saprolegniaceae studied was able to grow in a medium contg.  $K_2SO_4$  as the sole source of S, but all grew when a thio compd. (cysteine) was added. Twenty cultures (10 genera) of other parasitic fungi studied were able to use either form of S. Saprolegniaceae are parathiotrophic; the others are euthiotrophic.

**Experiments on the origin and function of berberine in *Berberis darwinii*.** Benjamin Thornton Cromwell. *Biochem. J.* 27, 800-72 (1933).—The alkaloid berberine, present in *Berberis darwinii*, accumulates in tissues which take no part in metabolic activities, and which are made up principally of dead elements. Synthesis of the alkaloid takes place in summer during the period of active growth. It appears that berberine is a product of protein metabolism; its synthesis is brought about by condensation of the products of protein breakdown and sugar residues.

**Transpiration of different modifications of one species *Th. Schmucker* and G. Drude. *Naturwissenschaften* 21, 676 (1933).**—The transpiration of leaves of *Impatiens noli tangere* grown on different soils and with differences in leaf size was found to be appreciably different. Per sq. dm. and mm. large leaves grown on leaf-mold soil evapd. 1.3-1.5 mg.; plants grown on almost pure sand evapd. 8-9 mg. Evidently plants on poor soil tend to work up as much  $H_2O$  as possible to obtain the necessary salts. The chlorophyll content per unit of leaf surface was for plants from heathy soil 2.5 times higher than for those from garden soil.

**A sugary exudation from sorghum.** T. R. Seshadri. *Madras Agr. J.* 21, 394-6 (1933).—From the beginning of the flowering season a sweet fluid exudes from the earheads of certain plants of a variety of sorghum known as *Tella jonna*. Analyses of 3 samples of the fluid, dried for 1 week over concd.  $H_2SO_4$ , gave ash 1.36-1.53, total sugar 79.0-80.6, reducing sugar 14.3-23.5 and sucrose 56.9-64.7%; the acid content was equiv to 7.75-8.60 cc. of  $N$  NaOH per 100 g. material. Starch and dextrin were absent. Fresh samples of the exudate contained yeasts and bacteria but no fungi. A 5% aq. soln. of the fresh exudate had a  $pH$  of 5.5; this decreased to 3.5 after 24 hrs. and to 3.2 after 48 hrs. Acid was the principal product of fermentation, very little alc. being produced.

**The mechanism of the effect of toluene on fermentation by yeast.** W. A. Bultzer. *Biochem. Z.* 265, 5-12 (1933).—The inhibitory effect of toluene on the fermentation of yeast is irreversible and cannot be removed by washing the cells. This is apparently not due to the loss of some substance through a change in permeability. Toluene poisoning generally does not injure the phosphatase of the cells.

**Phosphorylation by lactose yeast.** Eduard Hofmann. *Biochem. Z.* 265, 203-8 (1933).—The lactose yeast, *Saccharomyces fragilis* and lactose yeast Sp. 102, can form  $H_2PO_4$  esters of galactose. Large quantities of hexose-diphosphate, identical with fructose-1,6-diphosphate, were isolated together with small amts. of a monophosphate. The latter, on hydrolysis with taka-diastase, yields a free sugar which gives the Selivanoff keto reaction.

**Lactase in bottom yeast.** Eduard Hofmann. *Bio-*

*chem. Z.* 265, 209-12 (1933).—Bottom yeasts do not ferment lactose because they lack the lactase for splitting the disaccharide. However, if a suspension is digested with lactose soln. it acquires the ability to split lactose-ureide, setting free galactose.

**The chemical composition of the spores of vegetable parasites of cereals.** Silvia Campanile. *Nuovi ann. agric.* 12, 640-8 (1932); *Rev. Applied Mycol.* 12, 584-5.—A parallel may be established between the chem. compn. of cereal seeds and that of the spores of the fungi which attack them; the parasitism of the cereal smuts may be conditioned to some extent by alimentary needs, the specific nature of the attack on a particular host being partly due to the alimentary possibilities of that host. In the seeds,  $P_2O_5$  predominates over K while in the spores the reverse is true. It is thought that the large K content present in the spores of the cereal smuts may account for their tendency to induce cellular multiplication and the virulence shown by the promycelium toward growing tissues.

**Exanthema in pears and its relation to copper deficiency.** J. Oserkowsky and Harold E. Thomas. *Science* 78, 315-16 (1933).—The Cu content of leaves of Bartlett pear trees affected with exanthema was 3.1-5.1 p.p.m., irrespective of whether the appearance of the leaves was healthy or diseased. On the other hand, the Cu content of the leaves from trees free of the disease varied from 5.0 to 20 p.p.m., trees growing in an affected orchard being in general low. Exanthema is thus probably due to a deficiency of Cu. Spraying, or injection into the trunk, of sol. Cu salts gave marked improvement in the affected trees, but Fe, Mn and Zn salts were without effect.

**Chlorophyll (Armstrong) 10. Red sensitizing with chlorophyll (Kogel) 5.**

## E—NUTRITION

PHILIP B. HAWK

**Carotene and vitamin A.** Harry Goldblatt and Harold M. Barnett. *Proc. Soc. Exptl. Biol. Med.* 30, 201-4 (1932).—Biol. tests with albino rats showed that the color in carrot oil when considered as carotene was equal in vitamin A potency to an equiv. amt. of cryst. carotene. Carotene is probably the only growth-promoting factor of the order of vitamin A in carrots. Tests confirmed the findings of Polak and Stokvis (cf. *C. A.* 26, 4306) that 0.0005 mg. (0.5 $\mu$ ) of carotene satisfied the requirement for a Sherman Unit of Vitamin A; this would make 1 International Unit of Vitamin A (1 $\mu$  of pure carotene) the equiv. of 2 Sherman Units.

**The specific action of corn, barley and other grains on bone development.** J. C. de Ruyter de Wiedt and E. Brouwer. *Verlag. landb. Onderzoek. Rijkslandbouwproefsta.* No. 38C, 275-300 (1932).—Seventy-six parts of corn, barley, rye, wheat or oat meal (all made from the whole grains) mixed with 20 parts of gluten meal, 3 parts of  $CaCO_3$  and 1 part of NaCl caused various degrees of rickets in rats. Corn was the worst and barley the best while rye and wheat occupied intermediary positions from the point of view of producing rickets in rats. The effect of oats was uncertain, as the rats made insufficient growth on the oat diet. When the P content of the diets was brought to the same level by addn. of a small amt. of  $Na_2HPO_4$ , there was no appreciable change in bone formation or compn. The so-called "anticalcifying action" of the cereals needs further investigation, as this "action" in addn. to the vitamin D content of the cereals may be responsible for the sp. effect on bone development.

**An appraisal of antirachitosis in terms of rat and clinical units.** Alfred F. Hess and J. M. Lewis. *J. Am. Med. Assoc.* 101, 181-4 (1933).—A clinical test carried out on irradiated milk, "yeast milk," cod-liver oil and viosterol and controlled by biol. assays demonstrated that the antirachitic milks require from 85 to 40 and viosterol 600 to 800 (rat units daily) to confer protection or

effect healing. Irradiated milk is the most desirable antirachitic on a communal scale. The marked distinction between clinical and rat units implies that the present method of rating antirachitics is misleading.

Rachel Brown

A century of progress in the chemistry of nutrition. M. C. Sherman. *Sci. Monthly* 1933, 442-7. — E. H.

Vitamin B(B<sub>1</sub>) and G(G<sub>1</sub>) contents of cottonseed products. May L. Whitsitt. *Ind. Eng. Chem.* 25, 1169-71 (1933). — Cottonseed meal when fed to rats proved to be a good source of both vitamins B(B<sub>1</sub>) and G(G<sub>1</sub>). The oil contained neither. The hulls were rich in vitamin B(B<sub>1</sub>), had no B(B<sub>1</sub>), and showed evidence of a third factor of the vitamin B complex. Amy LeVesconte

Effect of carbon dioxide and sodium benzoate on vitamin C content of orange juice. Agnes F. Morgan, Catherine I. Langston and Anna Field. *Ind. Eng. Chem.* 25, 1174-6 (1933). — Frozen Valencia and navel oranges had the same vitamin C value. Na benzoate had no effect on vitamin C, while CO<sub>2</sub> protected it from oxidation. Amy LeVesconte

Some aspects of citric acid metabolism. Adrian C. Kuyper and H. A. Matill. *J. Biol. Chem.* 103, 51-60 (1933). The serum citrate concn. is increased in rabbits by NaHCO<sub>3</sub> alkalosis and diminished by NH<sub>4</sub>Cl acidosis and markedly by inanition. Analysis of the blood from various parts of the body failed to demonstrate any relation between any particular tissue and the oxidation of citric acid but blood from the renal vein contains less than that from the renal artery. The citric acid content of human urine increases slightly after each meal irrespective of the presence of the acid in the food. It is increased by vigorous exercise and by NH<sub>4</sub>Cl ingestion and increased by alkalosis produced by hyperpnea. The variations following the intake of food cannot be explained solely on the basis of acid-base relationships. When given in doses of 2-20 g., 1.5-2.5% escapes oxidation and is excreted in the urine so that citric acid is rapidly but not completely oxidized by the human organism.

A. P. Lothrop

The gaseous metabolism of pigeons during avitaminosis. G. Surana. *Arch. intern. physiol.* 36, 1-12 (1933). — The basal metabolism of pigeons is quite variable. On a diet of polished rice at a temp. of 29-30° the values are normal but at 12-15° the O<sub>2</sub> consumed is lower. Action of pilocarpine on the gaseous metabolism of pigeons during avitaminosis. *Ibid.* 13-17. — The injection of pilocarpine into pigeons fed polished rice increases the O<sub>2</sub> consumption. A decrease occurs, however, if the vitamin deficiency is marked. If these vitamin-depleted pigeons are injected with pilocarpine while they are being fed yeast there is a marked increase in O<sub>2</sub> consumption.

C. M. McCay

So called hypervitaminosis D. A synthetic critical survey and a personal contribution.\* Pietro Coccheri and Gioacchino Rossi. *Pediatrics* 39, 301-27 (1931); *Chem. Zentr.* 1932, II, 2182; cf. C. A. 27, 1921. — Injuries caused by large doses of vitamin D depend upon (1) unchanged ergosterol, (2) contamination of the ergosterol, and (3) toxic substances formed as the result of excessive irradiation. The degenerative effect is attributed to the unchanged ergosterol. The accompanying toxic substance cause hypercalcemia and heterotropic calcification. Excessive amts. of pure vitamin D produce hyperphosphatemia and excessive calcification of the bones. Therefore pure preps. are required for therapeutics.

M. G. Moore

Vitamins and infection. A. Frank. *Z. Vitaminsforsch.* 1, 51 (1932); *Chem. Zentr.* 1932, II, 396. — On the basis of some expts. and review of the literature the fact is accepted that the danger of infection is decreased by a vitamin-contg. diet and increased in avitaminosis and hypovitaminosis. All vitamins appear to be concerned. The manner in which vitamins function to prevent infection is discussed and left an open question.

M. G. Moore

The true antiscorbutic vitamin content of German foods.\* J. V. Hahn. *Z. Volksernährung Diätetik*

6, 337-41, 364-6, 372-3; 7, 5-6 (1932); *Chem. Zentr.* 1932, I, 1282. — One guinea pig unit (M.U.) was defined as the daily dose of food in g. necessary to keep the pig healthy. Fruit was found to be much poorer in vitamin C than older work had indicated. Black currants showed 200 M.U., strawberries 100, raspberries and gooseberries 50, red currants 33, apples about 10; pears and quinces in winter practically none, oranges and lemons 200, mandarins 50, bananas and pineapples 16, dates and figs little, and haws (after cooking) 100. A large no. of culinary plants were investigated, both raw and cooked, their stage of maturity also being considered. Results showed carrots 10, red cabbage 100, cooked about 15, white cabbage somewhat less, sauerkraut still less, spinach 16, cooked none, turnip 200, cooked about 30. Cabbage salad showed less than 20, endive salad about 20; raw beets, celery and onion were poor in the vitamin. Chives were rich (100), as were parsley (200) and horseradish (200), after cooking 50. Tomatoes showed only 20.

M. G. Moore

Influence of the food and environment of milk-producing animals on the vitamin content of their milk. Martin Schieblich. *Z. Volksernährung Diätetik* 7, 9 (1932); *Chem. Zentr.* 1932, I, 1963 4; cf. C. A. 27, 143, 2707. — The vitamin A stored while the animal is on pasture is so slowly used up that there appears no deficiency of this vitamin in the milk during the period the animal is kept in the stall. Vitamin B is formed in the paunch of the cow. There is a definite relation between the vitamin C content of the food and of the milk produced; silage gives milk rich in this vitamin. Vitamin D content is dependent upon food and environment.

M. G. Moore

Studies in purine metabolism. I. Exogenous purine metabolism in guinea pigs. Kozo Tomita. *Sei-kwaï Med. J.* 51, No. 5, 95-136 (English Abstract 4-5) (1932). — Normal guinea pigs fed on oatmeal or Sherman's vitamin-C-free diet plus fresh radish excrete 0.33-0.35 mg. of urinary uric acid N per day, 0.21-0.25% of total urinary N. Feeding a purine-contg. diet or pure purine does not increase uric acid excretion, although total N is proportionally increased. The av. uricolytic index of the normal guinea pig is 98.8 and the purine coeff. is 309. The end product of purine metabolism in this animal is allantoin, not uric acid. II. Endogenous purine metabolism in guinea pigs. *Ibid.* No. 6, 37-118 (English Abstract 25) (1932). — The end product of endogenous purine metabolism in guinea pigs is also chiefly allantoin, not uric acid, and it is decreased in summer, and increased in winter. The spleen does not take part in this metabolism, but if part of the liver (about 2/3) is removed, not only uric acid formation and decompn. are decreased, but also other purine metabolism is diminished. The endogenous purine metabolism is also diminished when the reticulo-endothelial system is blocked. S. T.

Production in dogs of chronic black tongue with anemia.

C. B. Rhoads and D. K. Miller. *J. Exptl. Med.* 58, 585 (1933). — By feeding a particular diet, apparently lacking a substance closely associated with vitamin B<sub>2</sub> (G), a chronic disease may be produced irregularly in dogs, characterized by atrophic glossitis, diarrhea, loss of wt. and anemia. The disease can be prevented and relieved by materials rich in vitamin B<sub>2</sub> (G). C. J. West

Activated lipoids. Standard Brands, Inc. *Brit.* 394, 408, June 29, 1933. Unsaponifiable lipoids, particularly ergosterol, are rendered antirachitic by treatment with ultra-violet light in soln. in a liquid consisting of, or contg., diethylene dioxide (dioxan). Other compatible liquids may be mixed with the diethylene dioxide, e. g., EtOAc, triethanolamine, C<sub>6</sub>H<sub>6</sub>.

## F—PHYSIOLOGY

HOMER W. SMITH

Effect of prolonged administration of the anterior pituitary-like hormone on pituitary and thyroid. J. B. Collip, H. Selye, D. L. Thomson and J. E. Williamson. *Proc. Soc. Exptl. Biol. Med.* 30, 580-1 (1933); cf. C. A.

- 24, 2781, 5812; 25, 1563, 3700.—In the female rat, the injection of anterior pituitary-like hormone (A. P. L.) caused parallel increases in wt. of the anterior lobe of the pituitary, of the ovaries and of the thyroid gland; in the male, the thyroid and pituitary did not enlarge. A. P. L. had no effect on the thyroids of hypophysectomized male or female rats. Production of exclusively thecal luteinization and continuous estrus with anterior-pituitary-like hormone. H. Selye and J. B. Collip. *Ibid.* 647-9. - A. P. L. injected daily into 30 rats from the 6th to the 26th day of life caused luteinization of the thecal cells, the formation of thecal corpora lutea and continuous estrus; there was no follicular maturation nor formation of normal or atretic corpora lutea. Hypophysectomized rats reacted similarly to the A. P. L.-injected immature rats. Further studies on production of thecal luteinization by means of A. P. L. H. Selye, J. B. Collip and D. L. Thomson. *Ibid.* 780-3. It is thought that the immature pituitary is unable to furnish a complementary substance necessary for the normal action of A. P. L. on the ovary; it becomes able to do so before normal puberty is reached and at this time A. P. L. will produce precocious puberty. Species differences in the reaction to A. P. L. may be due to differences in the ability of the pituitary to furnish the complementary substance. C. V. Bailey
- Further experiments on induction of ovulation in toads. I. A. Wills, G. M. Riley and E. M. Strubbs. *Proc. Soc. Exptl. Biol. Med.* 30, 784 6(1933); cf. *C. A.* 27, 3507, 3530. - Six *Bufo americanus* females were given daily implants of 4 hypophyses from gar pike (*Lepidosteus platystomus* Rafinesque and *L. osseus* L.); ovulation occurred in 5 surviving animals between the 2nd and 6th days; similar results were obtained with a female, *Rana pipiens*. Ovulation was not induced in 2 toads by implants of rat hypophyses. The maturity hormone among lower vertebrates may be non-specific. C. V. Bailey
- Thyroid hypertrophy as a response to the gonad-stimulating hormone of the pituitary. Oscar Riddle, Robert W. Bates and Simon W. Dykshorn. *Proc. Soc. Exptl. Biol. Med.* 30, 794 7(1933) Neither prolactin (cf. *C. A.* 27, 4289) nor the growth principle of the anterior pituitary caused hypertrophy of the thyroid when injected into doves and pigeons. Hyperplasia of the normally developed thyroid following pituitary administration is a specific response to the gonad-stimulating hormone or to another pituitary deriv. of similar soly.; good gonad-stimulating preps. do not invariably induce thyroid hyperplasia in doves and pigeons. C. V. Bailey
- Comparative studies of gonad-stimulating hormones. II. Influence of length of period of administration of certain extracts. C. F. Fluhmann. *Proc. Soc. Exptl. Biol. Med.* 30, 1014 10(1933); cf. *C. A.* 27, 2485. -The administration of a known total dose of ovarian-stimulating pregnancy blood ext. over periods of 10, 15 and 20 days produced a much greater increase in the wts. of the ovary and the uterus of the immature rat than when the same total dose was given in 5 days. Similar results were obtained with untreated human pregnancy blood serum, Antuitrin-S (Parke, Davis & Co.), Collip's A. P. L. (Eli Lilly and Co.) and Folliculin (E. R. Squibb and Sons). Opposite results were obtained with acid exts. of sheep anterior pituitary glands. C. V. Bailey
- Biological characteristics of ovary-stimulating extracts made from blood of pregnant women. C. F. Fluhmann. *Proc. Soc. Exptl. Biol. Med.* 29, 1193 5(1932). - A crude estrin-free ext. was prepd. from blood by a method based on that of Wallen-Lawrence and Van Dyke (cf. *C. A.* 26, 1968) for the extn. of "hebin" from anterior pituitary glands. This ext. readily induced luteinization in the ovaries of immature rats; it did not stimulate the rapid development of graafian follicles nor cause a great increase in ovarian wt. when given in large doses for 5 days. Induction of ovarian growth with an extract made from blood of pregnant women. *Ibid.* 30, 149 50(1933). In immature rats given 2 daily injections of pregnancy blood ext., equiv. to 0.22 cc. of the original blood plasma, over a period of 29 days, the ovaries weighed 84-293 mg.; the ovaries of control animals weighed 15-19 mg. The time factor is an important feature in comparing the effects of this hormone with those of fresh anterior hypophysial implants. C. V. Bailey
- Preparation of prolan, theelin and theelol from the same urine. Philip A. Katzman and Edward A. Doisy. *Proc. Soc. Exptl. Biol. Med.* 30, 1196-7(1933).—Adsorb prolan from the urine on  $\text{BzOH}$  as described by the authors (cf. *C. A.* 27, 702); strongly acidify the filtrate with  $\text{HCl}$ , let stand a few days, ext. the supernatant fluid with  $\text{BuOH}$  in the continuous extn. app. (cf. *C. A.* 24, 4545), distil off the solvent, leach the residue with benzene and remove by distn. Dissolve the residue from 100 gal. of urine in 1500 cc. of 80%  $\text{EtOH}$  contg. 150 cc. concd.  $\text{HCl}$ , boil 4 hrs., distil off the alc. and add solid  $\text{NaOH}$  until the soln. is alk. to phenolphthalein. Ext. the soln. with equal parts of  $\text{BuOH}$  and benzene and continue the process as described by Doisy and Thayer, beginning at step 3 (cf. *C. A.* 25, 5458). Purify theelol as the Na salt (cf. *C. A.* 27, 989). The yield of theelol is 2 5 mg. per gal. of urine. C. V. Bailey
- Female hormone (menformone) and secondary male sexual organs. J. Freud, S. E. de Jongh and E. Laqueur. *Nederland. Tijdschr. Geneeskunde* 77, 1109-17(1933).—The antagonistic influence of the female follicular hormone upon male sexual characters is explained by a checking action on the testicles or on the anterior lobe of the hypophysis. This effect is absent in castrated animals in which, on the contrary, some of the organs, such as the seminal vesicles, increase in size (cf. Loewe, *et al.*, *C. A.* 25, 5699 700). This observation cannot be explained by male hormones, present in the female hormone as an impurity, since even pure cryst. hormone produces such effects. Moreover, the growth of the seminal vesicles produced by cryst. hormone differs qualitatively from that produced by male hormone. R. Beutner
- Urea clearance test in pregnancy. A. Cantarow and G. Ricchiuti. *Arch. Internal Med.* 52, 637-46(1933). - In normal pregnancies urea clearance ranges from 28 to 184%. Clearance diminished toward the end of the period of gestation. It was high early in this period. J. H. Brown
- Mechanism of the inhibition of gastric function by fat. Robert K. S. Lim. *Quart. J. Exptl. Physiol.* 23, 263-8 (1933). -Only one chalone is responsible for the inhibition by fat of both gastric secretion and gastric motility. R. B.
- The minute- and stroke-volumes of the human heart in different positions of the body. I. L. Fisher. *Arbeitsphysiol.* 6, 111-32(1932).—The min.-vol. of the hearts of 5 females averaged 3.63 l. lying and 2.86 l. standing, and the stroke-vol. in the 2 positions averaged 56.2 and 42.9 cc. in the 2 positions. Five men showed similar differences. The sitting position gave values between those of the other 2 positions. T. M. Carpenter
- The respiratory exchange and energy requirement in mental work. D. E. Rosenblum. *Arbeitsphysiol.* 6, 214-34(1932). -In 41 expts. of 40 min. duration with the Douglas-Haldane method, severe mental work resulted in a 5% increase of energy output. T. M. Carpenter
- The choline and acetylcholine contents of animal tissues. Erich Strack, Ernst Neubauer and Heinrich Geissendorfer. *Z. physiol. Chem.* 220, 217-28(1933).—Fresh functioning liver of steers and dogs contains practically no free choline or acetylcholine. The free choline increases rapidly after the blood circulation has been interrupted; hence the physiol. content can be detd. only after very rapid fixation of the tissue. This increase is irregular and is especially noteworthy in the 1st and after the 4th hr.  $\text{EtOH}$  is unsatisfactory as a fixing agent. This accounts for the discrepancies and doubtful findings reported in the literature. Another source of error is a substance, probably a  $\text{H}_2\text{O}$ -sol. sphingomyelin, from which free choline can be formed by too high concn. of mineral acid during the process of isolation. A. W. Dax
- Role of glutathione in the Y reduction. Rawson J. Pickard. *Bull. soc. chim. biol.* 15, 781-9(1933); cf. *C. A.* 26, 4072. -Expts. are described on the detn. of the reducing factor Y of the blood. In normal blood

about half of the Y reduction is due to glutathione and the remainder to unknown substances. In many diseases the proportion of the latter is increased. Glutathione is eliminated by pptg. the corpuscles without laking. Twenty references. L. E. Gilson

Choline in opotheric powders. M. Rondeau Du Noyer and E. Kahane. *Bull. soc. chim. biol.* 15, 938-43 (1933).—Nearly all the powd. gland preps. used in opotheric contain choline, probably derived from lecithin by hydrolysis; hence the Florence  $I_2$ -KI reaction for choline cannot be relied on to identify testicular preps. L. E. Gilson

Physicochemical properties of hemocyanins. III. Jean Roche and Pierre Dubouloz. *Bull. soc. chim. biol.* 15, 954-68 (1933).—See C. A. 27, 3958. L. E. G.

The mineral matter fixed in the seminal cells during spermatogenesis. A. Pollicard. *Compt. rend.* 197, 710-11 (1933).—The ash patterns of incinerated sections of testicular tissue are described. L. E. Gilson

Is the thyroid-stimulating hormone of the anterior hypophysis eliminated by the kidneys and present in urine? Max Aron. *Compt. rend. soc. biol.* 114, 20-3 (1933).—Reply to Krogh and Okkels, C. A. 27, 4287. L. E. Gilson

Potassium content of the voluntary and involuntary striated muscles of young animals. A. Leulier, A. Bernard and G. Bérnard. *Compt. rend. soc. biol.* 114, 58-9 (1933); cf. C. A. 27, 2000. The K of the voluntary muscles of the cat, dog and pigeon increases during the first 10 days after birth as movement becomes more rapid, but in the new born guinea pig, which is able to move about rapidly as soon as born, the K is high at the beginning and does not change. No significant change occurs in the K of the heart muscle of any of the above species. L. F. Gilson

The carbohydrate metabolism of the chick embryo. Constantin Donhoff. *Biochem. J.* 27, 800-17 (1933). With regard to the carbohydrate content of the egg, the water-sol. fraction of the alc. ppt. can be subdivided into (a) not precipitable with phosphotungstic acid (the nature of this fraction is not known); (b) the ovomucoid sugar; and (c) precipitable with trichloroacetic acid and fermentable *in toto*, representing protein sugar. Glycogen is found both in the water-sol. and water-insol. portions. The total carbohydrate content of the egg varies between 272 and 296 mg. Free sugar reaches its lowest level on the 10th day and rises again slightly during the last days of incubation. Reduction in the water-sol. fraction of the alc. fraction of the alc. ppt. decreases in the first and increases in the second half of incubation. The reducing power of the water-insol. fraction of the alc. ppt. decreases from the start to the end of the ppt. Total carbohydrate diminishes till the 9th day. B. H.

The component fatty acids and glycerides of the milk fats of Indian goats and sheep. Das Ram Dhingra. *Biochem. J.* 27, 851-9 (1933). The fatty acids of the milk fats of goats and sheep are similar in compn., but differ from those of cow or buffalo butters in the higher content of the lower fatty acids. The content of the fully satd. glycerides in the 2 fats seems to be a function of the mean unsatn. The general properties and component glycerides of goats and sheep with fats are not very different from those of the cow and buffalo, and there is no reason why they should not be used as substitutes for the latter. Benjamin Harrow

The glycolytic mechanisms of brain. Charles A. Ashford. *Biochem. J.* 27, 903-10 (1933); cf. C. A. 26, 2473. Glucose breakdown to lactic acid by brain tissue is not inhibited by the presence of glycogen. When glucose and hexosemonophosphate or hexosediphosphate are present together, the glycolysis observed is the sum of the glycolyses produced from each substrate separately, showing that the enzyme systems responsible for the 2 effects are independent. When glucose and mannose are present together, the results show that the same enzyme is responsible for their breakdown. B. H.

Distribution of sulfur in goat hair. Dorothy Jordan. Lloyd and Robert H. Marriott. *Biochem. J.* 27, 911-14

(1933).—The cortex is sepd. from the medulla of goat hair by treatment with 4 N NaOH. The percentage content of S in the cortex is 8.60 and in the medulla 0.23. Benjamin Harrow

Calcium and phosphorus metabolism. John P. McGowan. *Biochem. J.* 27, 934-42 (1933).—The most important factor controlling the absorption of Ca and P appears to be the acidity of the gastric juice. The factor which influences the absorption of P is an excess of Ca in the diet, which, having neutralized the HCl, ppts. P as  $Ca_3(PO_4)_2$ . For the optimum utilization of Ca and P after absorption, they should be supplied in the food uncombined with one another. The Ca and P in the blood are prevented from interacting and to be held in soln. by the proteins. Benjamin Harrow

Some factors in the milk of individual cows which modify the growth of lactic streptococci. Hugh R. Whitehead and Geoffrey A. Cox. *Biochem. J.* 27, 951-9 (1933).—Milk contg. nos. of leucocytes in excess of 5 million per cc. gives rise to a rennet curd in which lactic streptococci are not able to develop normal quantities of acid. The influence of the cells is probably due to phagocytosis of the streptococci. The inhibitory action of the cells is eliminated by a heat treatment of the milk at 40-52° for 30 seconds. Benjamin Harrow

Fat metabolism. J. B. Brown. *Ohio J. Sci.* 33, 359-71 (1933). The subjects of hydrolysis of fats, the action occurring for the greater part in the duodenum, resynthesis, passage to the lymph and portal blood, oxidation in the normal and diabetic systems, and the deposition in the tissues and liver are reviewed. The fatty acids of high mol. wt. undergo the same reactions as fats. I. M. Levine

The blood picture of the turtle after complete anoxia. J. M. Johlin and Ferrin B. Moreland. *J. Biol. Chem.* 103, 107-14 (1933).—Turtles are very resistant to asphyxiation and may be kept in pure  $N_2$  for as long as 28 hrs. The blood sugar after such exposure to  $N_2$  may rise from a normal of about 50 mg. to about 1200 mg. and the lactic acid may also rise to almost 1000 mg. %. The turtle expires a larger amt. of  $CO_2$  than it would in the air during a similar period and the total  $CO_2$  output in complete anoxia is greater than could be accounted for by the bicarbonate of an amt. of turtle blood equal to the total wt. of the animal. The  $pH$  of the blood decreased from a normal of 7.9 to 6.8. It was not possible to identify methylglyoxal in the blood after anoxia. A. P. Lothrop

The rate of change of alkali reserve after ingestion of salts of organic compounds. I Normal variations in acid-base balance under basal conditions. Jane Cape and Elmer L. Severinghaus. *J. Biol. Chem.* 103, 257-60 (1933).—The acid-base levels ( $pH$ ,  $CO_2$  content and total base) in blood serums of 7 normal individuals under basal conditions showed no significant variations over a morning period of 5 hrs. Blood samples were taken hourly and the subjects were kept at absolute rest during the observations. A. P. Lothrop

The kinetics of blood pigments: hemocyanin and hemoglobin. G. A. Millikan. *J. Physiol.* 79, 158-79 (1933).—The comparative properties of hemoglobin and hemocyanin are: (1) time for disocn. to reach half completion; hemoglobin = 0.025-0.05 sec.; hemocyanin = 0.025-0.1 sec.; (2) character of disocn.; hemoglobin = monomol.; hemocyanin = monomol.; (3) effect of decreasing  $pH$  on rate of disocn.; hemoglobin = increase; hemocyanin = increase or small change; (4) effect of increasing temp. on rate of disocn.; hemoglobin = great increase;  $Q_{10}$  = 3.8; hemocyanin = probably great increase,  $Q_{10}$  = 2.27-3.8; (5) approx. rate of combination (half completion of assocn. process); hemoglobin = 0.003 sec.; hemocyanin = 0.003 sec. The hemoglobins of pig, man, sheep and frog have different rates of disocn., as do the hemocyanins of *Maia* and *Limulus*. J. F. Lyman

Albuminuria in the normal male rat. Muriel E. Bell. *J. Physiol.* 79, 291-3 (1933).—Urine from normal male

rats contains 0.5-0.8 g. per l. of a heat-coagulable protein. J. F. Lyman

The diffusion of lactate into and from muscle. S. C. Devadatta. *J. Physiol.* 79, 194 (1933).—The amt. of lactate diffusing into and out of resting and fatigued frog muscles indicates an apparent concn. of lactate in the water of the muscle of 20 mg. per 100 g. for rested, and 238 mg. per 100 g. for fatigued, muscle. Conclusion: All the water of muscle is available to dissolve lactate. J. F. Lyman

The influence of the parathyroid on the metabolism of creatine and phosphoric acid. C. G. Imrie and Constance N. Jenkinson. *J. Physiol.* 79, 218 (1933).—In animals whose parathyroids have been removed the concn. of muscle creatine phosphate is less than normal, and its rate of resynthesis following stimulation is much depressed. Treatment with parathyroid hormone restores to normal the rate of resynthesis of creatine phosphate. Feeding creatine along with parathyroid hormone raised the initial creatine phosphate of the muscle to values higher than normal. J. F. Lyman

Histamine in canine gastric tissues. Gertrude Gavin, E. W. McHenry and M. J. Wilson. *J. Physiol.* 79, 224 (1933).—Histamine, in relatively large amts., is present in the mucosa of the dog stomach. Stomach muscle contains lesser amts. Of the total gastric histamine about 80% is found in the fundic mucosa. The secretagog effect of stomach exts. disappears after incubation with histaminase. J. F. Lyman

The combined digestion of starch by the enteric juice and by amylase of different origins. Lorenzo Cioglia. *Boll. soc. ital. biol. sper.* 8, 489 (1933).—The amt. of reducing substances formed by the combined action of saliva and enteric juice is greater than the sum of the reducing substances formed by each acting separately. Hepatic exts. do not accelerate the action of enteric juice on starch when combined. Malt ext. accelerates the action of enteric juice on starch when combined. Peter Masucci

Glutathione under different experimental conditions. I. The influence of the pancreas on the glutathione of the blood and of the organs. R. Ferrari. *Boll. soc. ital. biol. sper.* 8, 508-11 (1933).—In depancreatized dogs, also in dogs subjected to a ligation of the ducts or to a permanent pancreatic fistula, little change in glutathione content of the blood or organs occurs within 1-2 days after the operation. After a longer interval the amt. of glutathione in the blood, liver, kidneys and muscle diminishes markedly; the glutathione of the suprarenals, on the contrary, increases almost 4 times that of the normal. II. The influence of the removal of the liver on the glutathione content of the blood and organs. R. Ferrari and L. Cadeo. *Ibid.* 511-13. —There is a diminution in the glutathione content of the blood and organs after hepatectomy of giant Hungarian frogs. The decrease is greater in the blood and muscles than in the other organs. This takes place immediately after the operation and persists till the death of the animal. Peter Masucci

The experimental hormonal hypercholesterolemia. R. Maurizio and E. Nardelli. *Boll. soc. ital. biol. sper.* 8, 545-9 (1933).—The blood of guinea pigs and rabbits, (males or females, mature or immature) was assayed for cholesterol content before and after the injection of urine from pregnant women. There was an increase of cholesterol of at least 30% and as high as 80% after the injection of the urine. The authors consider a case pos. if the increase of cholesterol is 30% when the cholesterol content of the blood was less than 0.35% before treatment; with values above 0.35%, they regard cases as pos. even with an increase of only 20%. The increase in cholesterol is not proportional to the amt. of anterior pituitary hormone injected along with the urine. P. M.

The action of pancreatic extract. Pietro Allerton and Giuseppe Borgatti. *Boll. soc. ital. biol. sper.* 8, 586 (1933). Peter Masucci

The permeability of the vitelline membrane of hen eggs.

A. Orru. *Boll. soc. ital. biol. sper.* 8, 585-9 (1933).—The vitelline membrane of egg yolk is permeable to glucose, sucrose and raffinose and the permeability is independent of the concn. of these substances present in the external liquid. Peter Masucci

The coagulation-inhibiting action of bile in vitro. II. H. Elbel. *Biochem. Z.* 265, 36-40 (1933); cf. C. A. 27, 1668. —The equil. of the system: protein- $\text{lecithin}-\text{Ca}$  which is essential for the coagulation of the blood is disturbed by bile salts. S. Morgulis

Ammonia formation and pyrophosphate decomposition in muscle. II. Wl. Mozolowski and B. Sobczak. *Biochem. Z.* 265, 41 (1933); cf. Barrenscheen and Filz, C. A. 26, 5110; Lohmann, C. A. 27, 272. —When muscle frozen in liquid air is ground the creatine- $\text{H}_2\text{PO}_4$  is the first to undergo decompn. while the decompn. of pyrophosphate and the formation of  $\text{NH}_3$  run almost parallel. It is possible to alter this experimentally by very brief incubation at low temp., so that the decompn. of pyrophosphate becomes more rapid than the  $\text{NH}_3$  formation, but the reverse condition has not been realized. The condition in muscles poisoned with  $\text{CH}_3\text{ICO}_2\text{H}$  is the same. S. Morgulis

The significance of the bile acids in carbohydrate metabolism. XXVI. Glycogen formation in the liver of splenectomized rabbits under the influence of adrenaline, cholic acid and spleen extract. Keizo Fujiwara. *Biochem. Z.* 265, 78-9 (1933); cf. C. A. 27, 2722. —Injections of small amts. of adrenaline (0.02 cc.) and oral administration of an aq. ext. of spleen (deproteinized with colloidal iron) increase the glycogen formation from glucose in the liver of splenectomized rabbits. The simultaneous administration of adrenaline and cholic acid, however, causes a diminution in the glycogen formation. XXVII. Glycogen formation in the liver under the influence of bile acids after castration. Hiroshi Takata. *Ibid.* 80-4. —The glycogen formation from glucose in the liver of male rabbits is increased, on the av. about 17%, by the administration of cholic acid. This effect is diminished after castration, more in case of ovariectomy than of orchectomy. The reduction in glycogen formation after castration is increased still further through the administration of cholic acid. There is, therefore, a close relationship between the glycogen-forming activity of cholic acid and the gonads. S. Morgulis

The histone of the bird erythrocytes. Th. Leipert and E. Leberl. *Biochem. Z.* 265, 115-23 (1933). —A bud erythrocyte histone, purified as the picrate, was analyzed. Of its total N 45.1% was in the form of basic N (25.02% arginine N, 3.03% histidine N, 17.05% lysine N). Of 100 N atoms 4.28 are present as amide N, and 8.37 N atoms react with  $\text{HNO}_2$ . By the Sorensen or Willstatter titration 10.05 and 10.16 basic groups are detd., but the Cl content of the HCl indicates the presence of 17.37 basic groups. From the analytical results it is further concluded that 1 of the  $\text{NH}_2$  groups of lysine is free, also that there are free guanidine and imino groups. The N detd. by formal titration and that detd. by methylation bear a ratio of 1:3 to each other. Reactive OH groups, if present at all, are in very insignificant amt. S. Morgulis

The role of iron in the glycolysis of blood and muscles. Hans Jakob Utvedt. *Biochem. Z.* 265, 154-8 (1933). —Unlike the experience with alc. fermentation, the addn. of  $\alpha,\alpha'$ -phenanthroline to blood checks the glycolysis only for the first 30 min. It seems, therefore, that it prolongs the induction period, but the glycolysis then starts up again and after 3 hrs. is as large as in the controls. On the glycolysis of the muscle ext. addn. of the reagent which binds the  $\text{Fe}^{++}$  ions has no effect at all. S. M.

The absorption of aluminum compounds in the organism and a consideration of the normal aluminum content of animal tissues. J. Wuhrer. *Biochem. Z.* 265, 169-80 (1933). —After 10-15 months of administering Al to dogs the Al content of their organs was not different from that of animals receiving ordinary food. Irritation of

the gastrointestinal mucosa occurs only when easily sol. Al salts are used in high concn. In human beings Al(OH)<sub>3</sub>, administered by mouth was recovered practically completely in the feces, and even in long expts. none of the Al appeared in the urine. Conclusion: Al salts are practically not absorbed. S. Morgulis

Decomposition of added methylglyoxal by blood and musculature. Ernst Auhagen. *Biochem. Z.* 265, 213-16 (1933).—Barrenscheen's (C. A. 27, 112) claim that methylglyoxal added to blood or muscle disappears explosively and that the amt. of lactic acid formed corresponds to only a fraction of the methylglyoxal lost could not be substantiated experimentally. S. M.

Absorption of fat by the intestine. P. Mahler and W. Nonnenbruch. *Med. Klin.* 28, 1380 (1932); *Bull. soc. sci. hyg. aliment.* 21, 283.—A discussion of the function of bile and of pancreatic secretion in the mechanism of the resorption of neutral fats by the small intestine. A. Papineau-Couture

The estrin content of sow ovaries. Fred E. D'Amour, Marie C. D'Amour, and R. G. Gustavson. *J. Pharmacol.* 49, 141-5 (1933).—Follicular fluid contained 950 rat units per l. Corpora lutea contained 65 rat units per kg. T. H. Rider

Effects of estrin and other hormones upon pregnancy. F. E. D'Amour, Marie C. D'Amour and R. G. Gustavson. *J. Pharmacol.* 49, 140-61 (1933).—If estrin is injected in rats by the tenth day in doses of 5-25 rat units daily pregnancy is invariably terminated and no other hormones can overcome this effect. T. H. Rider

The excretion of uric acid and urates by the bird. E. Gordon Young and Nicholas B. Dreyer. *J. Pharmacol.* 49, 162-80 (1933). The secretion of uric acid by the cockerel is discussed. Any substance which causes diuresis increases the secretion but no substance tried increased the uric acid concn. T. H. Rider

An artificial heart for dogs. O. S. Gibbs. *J. Pharmacol.* 49, 181-6 (1933). T. H. Rider

Recognition and comparison of prolan and prolan-like substances. Hubert M. Evans, Miriam E. Simpson and Paul R. Austin. *J. Exptl. Med.* 58, 561-74 (1933). The gonadotropic hormone of the blood of the pregnant mare has been greatly coned by adsorption on active Al(OH)<sub>3</sub>, followed by elution. The preps. so obtained gave demonstrable gonadotropic effects within 100 hrs. in 21-day-old female mice after 3 subcutaneous injections of 0.001 mg. in 1 cc. of physiol. saline. Injection of comparatively large doses of these preps. into immature male rats caused marked development of the testes, which in 10 days were tripled in wt. An astonishing increase in the wt. of the seminal vesicles resulted, for these organs were approx. 75 times heavier than in controls. C. J. West

Further studies on the hypophyseal substance giving increased gonadotropic effects when combined with prolan. Herbert M. Evans, Miriam E. Simpson and Paul R. Austin. *J. Exptl. Med.* 58, 545-59 (1933), cf. (C. A. 27, 3515). The hypophyseal substance the synergic factor—which gives increased gonadotropic effects when combined with prolan has been shown to itself possess a definite though slight gonadotropic activity. By means of isoelec. pptn. or by means of tryptic and cryptic digestion, fractions contg. the synergic principle were freed from many contaminants, in particular of the antagonistic factor. The synergic principle is unaffected by digestion with trypsin or trypsin followed by a short digestion with erepsin but the action of pepsin inactivated the material. A prep. of the active substance has been obtained which is potent in a total dose of 27 gamma. C. J. West

Acid-base equilibrium and pregnancy. Henri Vignes and Max Levy. *Compt. rend.* 197, 794-6 (1933).—V. and L. have detd. the ratio of chlorides in red blood cells and plasma during pregnancy. Changes in this ratio have been interpreted as being due to a gaseous alk. dosis, concurrent with rises in  $p_{H_2}$  of the blood. Julius White

## G—PATHOLOGY

### X. GIDEON WILLS

Is goiter due to an iodine deficiency per se? Harold Levine and Roe E. Remington. *J. Chem. Education* 10, 649-50 (1933).—A review of the literature on the exptl. evidence that factors other than I (cabbage, Ca, light, temp., seasonal variation, endocrine glands, vitamins, infection, chem. stimulation) are concerned in the etiology of goiter. One hundred and twenty-nine references.

Philip D. Adams

Alleged "reflex" ocular immunity. R. R. Madison. *Proc. Soc. Exptl. Biol. Med.* 30, 1013 (1933).—Rabbits were repeatedly injected in 1 anterior chamber with heat-killed or living *B. typhosus*; the agglutinin titer of the aq. humor of the vaccinated eye never exceeded 1/2 of the synchronous serum titer; the titer in the non-vaccinated eye never exceeded 1% of the serum titer. Contrary to Shamburov (*Z. Hyg. Infektionskr.* 114, 456 (1932)), no local or "reflex" synthesis of specific agglutinins occurred in ocular tissues. C. V. Bailey

Disturbance of mineral metabolism in generalized ostia fibrosa and in multiple myeloma. C. H. Lenshoek. *Nederland. Tijdschr. Geneeskunde* 77, 1193-203 (1933).—Description of a case of ostia fibrosa with parathyroid tumor and of a case belonging to the group of multiple myeloma. These 2 affections show many similarities, also in regard to the disturbance of mineral metabolism, particularly Ca metabolism. R. Beutner

Urea retention through lack of fluid. P. H. Verspijck and R. Maathuis. *Nederland. Tijdschr. Geneeskunde* 77, 2016-25 (1933).—Depletion of water in the body damages the kidney and leads to uremia; this may occur after vomiting or diarrhea and is often accompanied by a loss of salt. At the onset this kidney damage can still be repaired; later irreparable anatomical lesions appear. R. Beutner

Fluorescent urine. W. F. Wassink. *Nederland. Tijdschr. Geneeskunde* 77, 4035-38 (1933).—The fluorescence of certain pathol. urine samples is due to their content of mono- and di-acetyl indoxyl. R. Beutner

Reduction-oxidation determination in relation to carcinoma. N. Waterman. *Nederland. Tijdschr. Geneeskunde* 77, 4057-64 (1933).—The reduction-oxidation potential of the blood serum of cancer patients is detd. A high value or a large variability is an unfavorable prognostic sign. After Röntgen-ray irradiation the potential frequently decreases. The potential of quinone hydroquinone, or of methylene blue-rongalite, or cystine-cysteine (free from Fe) also decreases after irradiation. R. Beutner

Investigations on glycogen sickness. S. van Creveld. *Nederland. Tijdschr. Geneeskunde* 77, 4659-76 (1933).—Cases of hepatomegaly due to accumulation of glycogen in the liver are described. R. Beutner

Changes in the gastric acidity in peptic ulcer, cholecystitis and other diseases. Frances R. Vansant, Walter C. Alvarez, Joseph Berkson and Geo. B. Kusterman. *Arch. Internal Med.* 52, 616-31 (1933).—A study of gastric acidity, with a new technic (C. A. 26, 4088), is described in a no. of pathol. conditions, such as ulcer of the stomach and duodenum, cholecystitis and cholelithiasis. J. B. Brown

Nitrogen and sulfur metabolism in Bright's disease. IV. Retention of urea in the nephrosis syndrome. G. P. Grabfield. *Arch. Internal Med.* 52, 632-6 (1933); cf. C. A. 25, 5201.—In a patient with the nephrosis syndrome studied over a 36-day period ingestion of urea produced diuresis. Retention of urea occurred, but this urea did not appear as non-protein N in the blood. The retained N may be stored as "flesh" to replace tissue protein which has been lost as serum proteins in the urine. J. B. Brown

Food and goiter. Robert McCarrison. *Brit. Med. J.* 1933, II, 671-5.—"The more perfect the constitution of the diet the more normal is the thyroid gland, both as to size and as to its action." J. B. Brown

**Canine distemper.** The high antigenic value of the virus after photodynamic inactivation by methylene blue. J. R. Perdau and C. Todd. *J. Comp. Path. Therap.* 45, 78-80 (1933).—The virus of canine distemper as it exists in filtrates or other fluids devoid of living cells is rapidly inactivated by the photodynamic action of methylene blue. The antigenic value of the vaccine is ultimately reduced by prolonged or excessive irradiation. Drying the vaccine does not appear to affect its immunizing properties.

Rachel Brown

**Sedimentation rate and blood proteins in colitis.** M. Rachmilewitz and A. Rosenberg. *J. Egyptian Med. Assoc.* 16, 924-31 (1933).—In spastic colitis the sedimentation rate of the erythrocytes is reduced from a normal of about 5 hrs. to over 10 hrs. in most cases. The globulin ratio of the blood proteins is also lowered. R. and R. suggest that this disease is allergic in nature.

Rachel Brown

**The production of tuberculous tissue and hypersensitivity to tuberculin in guinea pigs.** C. H. Boissevain. *Am. Rev. Tuberc.* 27, 595-9 (1933).—During the purification of the phosphatide from the tubercle bacillus, the power to provoke the formation of tuberculous tissue and the power to cause hypersensitivity to tuberculin are lost simultaneously. No concn. of the material that causes the formation of tuberculous tissue takes place during the prepn. of the phosphatide. Most of the biol. activity of the tubercle bacillus remains in the residue after removal of the lipoids, carbohydrates and sol protein. This residue contains an insol. protein.

H. J. Corper

**The lysis of tubercle bacilli in vitro. Further observations.** H. J. Corper. *Am. Rev. Tuberc.* 28, 138-43 (1933).—The loss of acid fastness (lysis) of tubercle bacilli in tissues (dog liver, spleen and kidney) sterilized by means of an equal vol. of 6%  $H_2SO_4$  for 30 min to 1 hr. and washed with sterile saline soln. is due to the acidity retained by the tissues, and is not, as previously reported, caused by the action of autolytic enzymes. The  $H_2SO_4$  treatment apparently destroys the enzymes in the tissues and, when properly neutralized, preps. these tissues so that they can be utilized as a nutrient by the tubercle bacillus at incubator temp. Tubercle bacilli added to  $H_2SO_4$ -treated tissues, which have been neutralized by suitable alkalis ( $NaOH$ ,  $Na_2CO_3$  or  $NaHCO_3$ ) so that the reaction approximates the neutral point  $pH$  6.5-8, retain their viability for over 2 months at 37°. At refrigerator temp. (about 2°) heavy suspensions (about 0.1 mg. per cc.) may remain viable within a range of about  $pH$  4.5-9.0 for over 2 months. The effects of enzymes (autolytic and digestive) upon the viability and the chem. and morphological integrity of the tubercle bacilli still remain to be disclosed and await the development of suitably controlled tests and appropriate methods which will ensure sterility and the integrity of the enzyme being tested over the long period of time required for such action to be discerned. The  $pH$  of the medium in which the enzyme acts will require careful control to obviate misinterpretation.

H. J. Corper

**Auto-antibodies in tuberculosis.** O. Fischer. *Z. Tuberc.* 68, 5-6 (1933).—F. found that a certain no. of tuberculous sera gave a pos. complement-fixation reaction with alc. lung exts. It could not be detd. with certitude whether the reaction is due to the presence of lung lipid antibodies in the tuberculous serum or whether it depends on serum lability. To det. this further studies are essential. The ability of certain tuberculous sera to react with alc. heart exts. is, in all probability, due to serum lability.

H. J. Corper

**Physicochemical properties of tissues in relation to the normal and pathological states of the organism.** XVI. New discoveries on cancer caused by electrical conditions. F. Viès and A. de Coulon. *Arch. phys. biol.* 10, 119-26 (1933); cf. *C. A.* 27, 5401.—The incidence of spontaneous cancer in mice was much greater among those kept in metal cages electrically insulated from the earth than among those kept in similar, but grounded, cages.

L. E. Gilson

**Elimination of chlorides in pemphigus.** P. Popchrioff and R. Zorn. *Compt. rend. Soc. biol.* 114, 5-7 (1933).—Report of a case with marked chloride retention. Elimination of chlorides in eczema. *Ibid.* 8-10.—Chloride retention frequently occurs in eczema. Some biopsy specimens of eczematous skin showed twice the normal Cl content.

L. E. Gilson

**The platinum electrode potential of the crystalline lens in cataract.** J. Nørdmann and P. Reiss. *Compt. rend. Soc. biol.* 114, 12-13 (1933).—The normal cryst. lens has an  $r_H$  of 18; in cataract the  $r_H$  averages 20.6. L. E. G. Buffer coefficient curves of cerebrospinal fluid. N. Bernstein. *Compt. rend. Soc. biol.* 114, 28-31 (1933); cf. *C. A.* 25, 5201.—The buffer coeff. curves, as detd. by the Sb electrode, for cerebrospinal fluids from 10 different pathol. cases are given for the  $pH$  range 2-11.

L. E. Gilson

**Cataphoresis and some serological properties of cerebrospinal fluids.** N. Bernstein. *Compt. rend. Soc. biol.* 114, 32-4 (1933).—The isoelec. and neutral points of 15 pathol. cerebrospinal fluids were detd. by cataphoresis expts. covering the  $pH$  range 4-9.5. The alexin and hemolysin contents were also investigated.

L. E. G.

**Glucemia. Its physiological variations in non-diabetic pathological cases.** M. R. Cavex and M. Schteingart. *Compt. rend. Soc. biol.* 114, 78 (1933).—The extreme limits of glucemia found in the 1000 cases studied were 0.04 and 0.16%. In 450 cases the values were between 0.09 and 0.1 and in 300 cases less than 0.09. Diurnal and seasonal variations were slight.

L. E. Gilson

**Mineral equilibrium of the blood and nephropathy.** Renato Molise. *Minerva med.* 1933, II, 506-12.—A discussion and review of the literature are given.

Helen Lee Gruchl

**Metabolism of normal and tumor tissue. VIII. Respiration in fructose and in sugar-free media.** Frank Dickens and Guy Drummond Greville. *Biochem. J.* 27, 832-41 (1933).—cf. *C. A.* 27, 1045.—The brain, retina, testes, kidney and spleen all oxidize glucose, though to differing extents. The respiration of embryonic tissues falls very little when deprived of glucose. The respiration of Jensen rat sarcoma is not decreased in the absence of glucose. The various tissues studied oxidize fructose to a greater or less extent. Jensen rat sarcoma has the same R. Q. in glucose and in fructose.

B. H.

**Sensitizing action of synthetic porphyrins.** W. Hausmann and F. M. Kuhn. *Biochem. Z.* 265, 105-9 (1933).—Since synthetic mesoporphyrin, isuroporphyrin and coproporphyrin have a photodynamic effect on blood agar plates this cannot be attributed to any impurities but must be regarded as a function of the porphyrins. Synthetic mesoporphyrin has a very strong sensitizing action in the visible and in the long ultra-violet spectrum, but isuroporphyrin and coproporphyrin act slightly with 365 m $\mu$  wave lengths, and practically not at all in the invisible range of the spectrum.

S. Morgulis

**Investigations on the physicochemical properties of tissues in relation to the normal or pathological state of the organism.** XVII. Recent studies on the statistical evolution of cancer as caused by tarring. F. Viès, A. de Coulon and A. Ugo. *Arch. phys. biol.* 10, 304-17 (1933); cf. *C. A.* 27, 5401.—In a statistical study of cancerization in mice, the progress of infection has been explained by means of 3 parameters, compared to those of a test standard previously detd. By this method modifications of cancerization have been studied as caused by radiation and varying types of tar; the influence of soils, metals, darkness and finally the presence in the feed of various organs playing a part in diastase or hormone deficiency has been detd. Feeding with these organs (suprarenals, testicles and digestive tube) produces a considerable decrease of cancerization.

W. J. Peterson

**Immunological study of native, denatured and reversed serum albumin.** Benjamin F. Miller. *J. Exptl. Med.* 58, 625-33 (1933).—Native and reversed horse serum albumin are indistinguishable when tested immunologically by means of the precipitin reaction. C. J. West

A. N. RICHARDS

**Ferric chloride in the treatment of secondary anemias of infants.** L. N. da Gama Filho. *Rev. brasil. med. pharm.* 9, 27-36(1933).

E. S. G. Barron

**Monosodium thyroxine, desiccated thyroid and an impure potassium salt of thyroxine.** Willard O. Thompson, Phebe K. Thompson and Lois F. N. Dickie. *Arch. Internal Med.* 52, 576-92(1933); cf. C. A. 27, 2494. — Synthetic thyroxine by mouth is considerably less effective in raising the basal metabolism in myxedema than is its monosodium salt. Considerable differences are shown between the different preps. of thyroid, which were tested, by the various methods of administration.

J. B. Brown

**Anesthetics from the practical and scientific aspects.** F. J. Morrin. *Brit. Med. J.* 1933, II, 636-8.—A review.

J. B. Brown

**Antimalarial chemotherapeutic tests at the Devon mental hospital.** S. P. James. *J. Trop. Med. Hyg.* 36, 289-91(1933).—Atelrin but not quinine or phen-quinine prevented entirely the onset of the malarial attack within the usual incubation period of the disease.

Rachel Brown

**The adsorption of nicotine by the formed elements of the blood.** A. I. Burstein. *Arbeitsphysiol.* 6, 105-10 (1932).—After the injection into dogs of 0.3 mg. of nicotine per kg. body wt. the nicotine was exclusively adsorbed by the formed elements of the blood. *In vitro* expts. showed that the adsorption capacity for nicotine of the formed elements of dog blood was equiv. to 0.006-0.007 mg. per g.

T. M. Carpenter

**Sanocrysin treatment in tuberculosis.** K. J. Heinrichsen and H. C. Swamy. *Am. Rev. Tuberc.* 28, Suppl., 1-45(1933).—The authors found 50% of tuberculous patients with a stationary or downward progressive advanced tuberculosis of the "B" or "C" types, when given Sanocrysin in well-regulated doses, showed: (1) a rather prompt cessation of symptoms which tended to be permanent if the patient observed the usual measures of hygiene, (2) a clearing of tuberculous infiltrations, with marked fibrosis and contraction of cavities in roentgenograms and (3) changes from unfavorable to favorable lab. findings. Of the remaining 50% in those showing temporary improvement there was a shortening of the convalescent period or prolongation of life or both. There seems to be a real indication for the drug's use as a supportive treatment in collapse therapy, when patients are not doing well, and when a spread to the other side is beginning.

H. J. Corpe

**The action of formaldehyde on the tubercle bacillus; formalin disinfection in tuberculosis.** Joseph Hohn and Werner Herrmann. *Z. Tuberk.* 68, 145-56(1933). The disinfection of rooms with formalin is the most efficient method of killing tubercle bacilli in the homes of consumptives. Even the bacilli found in the depth of various materials are affected by the formaldehyde gas. In the Statg. Hospital in Essen formalin disinfection in closed app. is displacing steam disinfection, and this kills tubercle bacilli at a depth and protects the most delicate materials. For the purpose of testing disinfection app. and microorganism-destroying solus. the culture of tubercle bacilli on egg nutrient media from silk threads contg. pure cultures after exposure is considered an exact and certain method of test. An introductory review of the literature is given.

H. J. Corpe

**The cumulation of the digitalis glucosides.** H. Bauer and K. Frommherz. *Klin. Wochschr.* 12, 973-6(1933).—Thirty-five % of the immediately lethal dose of digitoxin in the continuous infusion method of Magnus will kill cats in 14 days with evidence of heart damage. Moreover, the drug disappears from the heart much faster than has been supposed. Clearly, it is necessary to differentiate between the cumulative effect of the drug observed even after a single injection, and the cumulation of the drug itself in Hatcher's sense, obtained with intravenous injections of <0.5 mg./kg. every other day.

1 The degree of the true cumulative effect is given by the difference between the immediately fatal dose and that which kills after a definite time interval. So measured, digitoxin is much more cumulative than gitalin, and prepn. contg. both take an intermediate position.

Harry Eagle

**The succagagic and hypoglycemic properties of secretin.** Jean LaBarre and Jules Ledrut. *Bull. soc. chim. biol.* 15, 724-63(1933).—A method is given for prep. secretin free from hypotensive principles. This product stimulated both the internal and external secretion of the pancreas of dogs and attempts to sep. it into the resp. hypoglycemic and succagagic principles by several commonly used fractional pptn. methods failed. Two pptns. by  $\text{CCl}_3\text{CO}_2\text{H}$  or  $\text{KClO}_4$ , however, split the secretin mols. into 2 new products, which were sepd. The product *incretin* was purely hypoglycemic in action, and the other, *excretin*, purely succagagic. The latter had the higher mol. wt. Seventy references.

L. E. Gilson

**Action of sodium thiosulfate in carbon monoxide poisoning.** M. Chambon and G. Bouvet. *Compt. rend. soc. biol.* 114, 45-6(1933).—Dogs receiving 10 g.  $\text{Na}_2\text{S}_2\text{O}_3$  intravenously did not recover any faster than untreated dogs poisoned to the same degree with CO.

L. E. G.

**Specificity of the detoxifying action of amino acids.** F. Figari and L. Sivori. *Compt. rend. soc. biol.* 114, 53-5(1933).—The mixt. of amino acids obtained by digesting any particular protein, toxin or species of bacteria seemed to have a specific detoxifying action upon the agent from which it was derived.

L. E. Gilson

**Hypotensive properties of the blood during peptone shock.** L. Jung. *Compt. rend. soc. biol.* 114, 56-7 (1933).—Peptone shock differs from anaphylactic shock in that it does not cause the appearance of a hypotensive agent in the blood. Expts. with dogs are described.

L. E. Gilson

**Comparative toxicity of tryptaflavine and gonacrine in rabbits.** M. Levrat and F. Morelon. *Compt. rend. soc. biol.* 114, 60(1933). Tryptaflavine is gonacrine-HCl. Both compds. are equally toxic for the rabbit. The M. L. D. is 0.3 mg. per kg., intravenously. Chronic renal lesions in rabbits following tryptaflavine intoxication. *Ibid.* 61-2.—A severe and prolonged nephritis is produced by 0.2-0.3 mg. given intravenously.

L. E. Gilson

**The therapeutic action of foudaine on canine filariasis.** F. Popesco. *Compt. rend. soc. biol.* 114, 219-20(1933).—The drug is effective.

L. E. Gilson

**Rules of chemotherapeutic action.** R. Schnitzer. *Naturwissenschaften* 21, 681-3(1933).—A review.

B. J. C. van der Hoeven

**The behavior of cats to heroin.** Luigi Scremin. *Boll. soc. ital. biol. sper.* 8, 522-3(1933).—Cats may become partially habituated to heroin.

Peter Masucci

**Tobacco intoxication and cardiac glycogen.** Mario Mattioli. *Boll. soc. ital. biol. sper.* 8, 543-5(1933).

Peter Masucci

**The toxicity of sodium fluoride.** A. Constantini. *Boll. soc. ital. biol. sper.* 8, 573-6(1933).—NaF in large doses is more injurious when given by the intrapleural or intraperitoneal than the gastric route; given in small doses, 0.02 g. per kg. of guinea pig, it is well tolerated by the pleural and peritoneal but is rapidly lethal by the gastric route.

Peter Masucci

**The toxicity of certain organ extracts injected intravenously and its interpretation.** P. Mascherpa. *Boll. soc. ital. biol. sper.* 8, 613-16(1933).—Liver, lung, kidneys and striated muscle exts. were prep. by subjecting the resp. tissues to a pressure of 350 atms. in a Buchner press. The filtered juices were injected intravenously into rabbits. The animals showed a typical anaphylactic shock terminating in death. The order of toxicity was: lung, muscles, kidneys, liver. A current of air rich in Ra emanations was bubbled through the exts. for 12 hrs. The intravenous injection of these proved as toxic as the untreated ones. The toxicity of the exts. is ascribed to the flocculation of the colloidal particles in the blood stream with consequent embolism and death.

P. M.

**Lathyrism in Syria.** Guy Loisel. *Presse méd.* 41, 1 449-50(1933).

**Influences of insulin on the water metabolism in health and in diabetes.** Fritz Winter. *Acta Med. Scand.* 80, 136-53(1933).—In healthy persons injection of insulin brings about concn. of the blood. In diabetics under insulin treatment there is also a concn. of the blood but to a smaller extent than in the normal after a single injection.

**The effect of minute quantities of copper on the mammalian organism. Influence of minute concentrations of heavy metals on the decomposition of glycogen in vitro.** Hans Handovsky, Daisy v. Cotzhausen and Ruth Schallehn. *Biochem. Z.* 265, 110-14(1933).—Expts. with a 0.46% soln. of glycogen show that during 45 min. incubation  $\text{CuSO}_4$  in concns. of  $10^{-4}$ – $10^{-3}$  m. can form 6-10% of reducing substance from it. Within these concn. limits only Cu and Fe salts were effective but salts of Mn, Co, Zn, Ag or Hg were inactive. The increase in reducing substance was twice as large in a KCl soln. of glycogen as in an aq. soln. HCl or  $\text{H}_2\text{SO}_4$  was effective only in concn. of or above  $10^{-3}$  m.  $\text{CuCl}_2$  in concns. of  $10^{-4}$  to  $10^{-3}$  was always inactive.

**Further studies on the biological value of metals. III. Reciprocal relation between metals and foodstuffs.** J. Schwaibold and P. Fischler. *Biochem. Z.* 265, 124-32(1933).—Al salts in a concn. of 20 mg. Al per l. have no ill effects on frog tadpoles; Zn salts even in a concn. of 2 mg. Zn per l. are very injurious, inhibiting completely the growth of the tadpoles in 4 weeks and causing many to die, but the animals can still be saved. Ni salts in a concn. of 2 mg. Ni per l. are likewise decidedly toxic. The corrosion products of Pb at  $75^\circ$  are sufficiently toxic that all animals were killed off within 1 month. A concn. of 2 mg. Pb per l. added in the form of Pb salts suffices to kill most of the exptl. animals and causes irreparable injury to the rest. Sn is fairly indifferent and in a 2 mg. per l. concn. causes only a slight suppression of growth and development of the tadpoles. Mice manifest a higher resistance to Cu than do tadpoles, but even for these it is very toxic. But Ag is more toxic even than either Pb or Cu, and 1 mg. per l. kills most of the animals in a few hrs. The corrosion of Hg by ordinary tap water kills tadpoles in 10-20 days, but the corrosion of Au or Pt is so slight that it produces no effect on them. Cf. C. A. 25, 2772.

**A photometric study of the action, in vitro, of mineral waters on blood serum.** P. Pontus. *Arch. phys. biol.* 10, 318-26(1933).—Since the globulins of blood serum are insol. in distd. water, and relatively sol. in saline solns. of various concns., the photometric method of examn. is convenient in following the phase of the action of mineral waters on blood serum. The product  $\delta_1$ , for a given diln., is a function of the nature of the mineral water employed in making the serum diln. Depending upon the saline concn. of the water studied, the curve,  $\delta_1 = f(1)$ , approaches that of distd. water or of NaCl at 8 pts. per 1000.

**Calcium. VII. Calcium effects on thoracic lymph flow of dogs.** Arnold L. Lieberman. *J. Pharmacol.* 48, 293-9(1933); cf. C. A. 27, 3253.—Ca salts, especially the acid salts, retard lymph flow in dogs when rapidly injected. Ca decreases tissue cell permeability. VIII. **Therapeutic effect of calglucon (calcium gluconate) on thrombophlebitic edema.** Arnold L. Lieberman and Leo M. Zimmerman. *Ibid.* 301-4.—The subcutaneous injections of Ca gluconate and of parathormone (Ca orally to a lesser extent) hasten the disappearance of exptl. thrombophlebitic edema presumably by diminishing the permeability of the capillaries previously increased by pathol. conditions.

**The mechanism of vomiting induced by quinidine. I. Quinidine emesis in animals with denervated hearts.** A. Carlton Ernestine and Samuel Lewis. *J. Pharmacol.* 48, 805-10(1933).—Vomiting, a common toxic symptom of quinidine (I), is produced by the oral or parenteral administration of I to cats even after denervating the heart. Since the heart is not the seat of the emetic action

of I, vomiting does not indicate that the full therapeutic effect of I on the myocardium has been attained. II. *Ibid.* 359-69(1933).—Quinidine does not produce emesis when applied to the 4th ventricle; it apparently works by peripheral action. The emetic action is abolished by nicotine or ergotoxine but is not inhibited by atropine, vagus section or evisceration.

**The effect of anthelmintics on the host. I. Tetrachloroethylene. II. Hexylresorcinol.** B. V. Christensen and H. J. Lynch. *J. Pharmacol.* 48, 311-16(1933).—Hexylresorcinol in single therapeutic doses causes no apparent symptomatic disturbances although repeated doses cause pathol. changes in the small intestine, liver and heart. Tetrachloroethylene in therapeutic doses causes considerable cardiac and respiratory depression, pathol. changes in the small intestine, liver and kidney.

**The development of tolerance to nicotine by rats.** A. Behrend and C. H. Thienes. *J. Pharmacol.* 48, 317-25(1933).—Adult rats developed no tolerance to repeated injection of nicotine, and young rats developed tolerance to min. effective and min. convulsive doses but not to min. lethal doses. The acquired tolerance of young rats may be due either to conditioned inhibition or to increased tissue resistance and increased destruction or excretion.

**The effect of cyanides on the thyroid gland of chickens.** A. W. Spence. *J. Pharmacol.* 48, 327-31(1933).—Chickens are extremely resistant to  $\text{CH}_3\text{CN}$ , the injection of 3 cc. resulting in no more than a narcotic effect. Presumably the CN is not split off by the chicken body. Repeated large doses have some goitrogenic action. The ability of chickens to synthesize their own vitamin C (hexuronic acid) and the known antigoitrogenic effect of plants rich in hexuronic acid probably explain these facts.

**The physicochemical properties of some new choline derivatives in relation to their chemical constitution and pharmacological action.** W. F. von Oettingen and R. O. Bowman. *J. Pharmacol.* 48, 333-40(1933).—*Choline dichloride* (II), *dicholine dichloride* (II) and *trimethyl ammonium ethylamine chloride* (III) have pharmacol. actions similar to that of choline (V). The quant. differences are discussed. I, II, III and IV in 0.01 M concns. do not affect the surface tension and are not appreciably oil-sol. They do not ppt. serum or lecithin emulsions and do not affect the sedimentation of red blood cells. The velocity of their diffusion through living frog skin is in inverse ratio to their pharmacol. action. V may be detd. by its orange-red color reaction with Major and Welbel's guanidine reagent (10% Na ferrocyanide, 1 part; 10% NaOH, 1 part; 10% Na nitroprusside, 1 part; water, 9 parts) within limits of 0.08 mg. I and II are detd. by evapn to dryness, soln. in 0.5 cc. water, pptn. with 0.5 cc. of Kraut's reagent (to 27.2 g. KI in water is added 8 g. Bi subnitrate in 20 g.  $\text{HNO}_3$  (sp. gr. 1.18); the resulting soln. is aged and filtered, then made up to 100 cc. with water). The ppt. is filtered, washed by suction with 3 cc. of  $\text{H}_2\text{O}$ , then 3 cc.  $\text{C}_2\text{H}_5\text{OH}$  and dissolved in 4 cc. warm  $(\text{CH}_3\text{OH})_2$  and the color matched with standards similarly prepd. III and IV are detd. by means of a sharp color reaction with Tolin's amino acid reagent.

**Liver damage in dogs and rats after repeated oral administration of cinchophen, ethyl ester of p-methylphenylcinchoninic acid (tolysin) and sodium salicylate.** Henry G. Barbour and Merl E. Fisk. *J. Pharmacol.* 48, 341-57(1933).—Cinchophen (I), tolysin (II) and Na salicylate (III) all produce liver damage in repeated doses. The order of toxicity is stated to be  $\text{I} > \text{III} > \text{II}$  for rat liver and rat kidney although III did not produce bromosulfalein retention while I did markedly and II slightly when all were used in max. dosages. For dog kidney the order of toxicity is stated to be  $\text{III} > \text{I} > \text{II}$ . I, but neither II nor III, caused gastric or duodenal ulcers. The amts. of II and III required to produce liver damage were far greater than clinical dosages. I, however,

should be used clinically only with great caution.

T. H. Rider

The local anesthetic action of *p*-aminobenzoate of diethylamine ethoxy alcohol. W. H. Horne and R. L. Shriner. *J. Pharmacol.* 48, 371-4 (1933).— $\text{CH}_3\text{CH}_2\text{O}$

and  $(\text{C}_2\text{H}_5)_2\text{NH}$  yield  $(\text{C}_2\text{H}_5)_2\text{NCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{OH}$  (I), b. 92-5°;  $(\text{C}_2\text{H}_5)_2\text{N}(\text{CH}_2\text{CH}_2\text{O})_2\text{CH}_2\text{CH}_2\text{OH}$  (II), b. 123-8°;  $(\text{C}_2\text{H}_5)_2\text{N}(\text{CH}_2\text{CH}_2\text{O})_3\text{CH}_2\text{CH}_2\text{OH}$  (III), b. 164-72° and  $(\text{C}_2\text{H}_5)_2\text{N}(\text{CH}_2\text{CH}_2\text{O})_4\text{CH}_2\text{CH}_2\text{OH}$  (IV), b. 190-200°. The amino alcs. in PhH were caused to react with  $\text{NO}_2\text{C}_6\text{H}_4\text{COCl}$ , yielding oily hydrochlorides of the esters. The free bases were obtained by shaking with  $\text{Et}_2\text{O}$  and dil.  $\text{NaOH}$  and reduced with  $\text{H}_2$  and Pt black in  $\text{C}_2\text{H}_5\text{OH}$ . All *p*-aminobenzoates were noncrystd. oils. Their hydrochlorides in 1% soln. had the following properties in order of toxicity to white rats in mg. per kg.: duration of anesthesia from intracutaneous injection into guinea pigs, duration of anesthesia from topical application to rabbit cornea: I 60, 58, 30-45; II 30-60, 113, 10-14; III 30-60, 109, 20; IV 60, 108, 0. II, III and IV caused pitting of cornea and necrosis in rabbit skin. I caused no necrosis, but temporary opacity of the cornea.

T. H. Rider

Determination of the toxicity of neocarsphenamine. I. The increase in toxicity on exposure to air. C. A. Morrell and C. W. Chapman. *J. Pharmacol.* 48, 375-90 (1933).—Increased toxicity of a 4% aq. soln. of neocarsphenamine on standing in air is prevented by overlaying with mineral oil. Unprotected solns. increase in toxicity 107% in 15 min. II. The characteristic curve for rats. *Ibid.* 391-400. A curve for the toxicity of neocarsphenamine in rats is presented. Individual variations in one colony of rats are 211%.

T. H. Rider

Febrile, respiratory and some other actions of dinitrophenol. M. L. Tainter and W. C. Cutting. *J. Pharmacol.* 48, 410-20 (1933).— $\alpha$ -Dinitrophenol (I) in doses of 3-40 mg per kg. produces increases of 6-7° in temp within 1 hr. lasting several hrs., respiratory stimulation, increased pulse rate and increased tissue metabolism in rabbits, cats, dogs, rats, pigeons and men. Death may result from direct circulatory depression, hyperpyrexia or acidosis and anoxemia. I produces no augmentation of fermentation of sugar by yeast *in vitro*.

T. H. R.

Cumulative poisoning by squill derivatives and by ouabain. E. W. Wallace and H. B. Van Dyke. *J. Pharmacol.* 48, 430-44 (1933).—*d*-Scillouin ( $\text{C}_{10}\text{H}_{15}\text{O}_5$ ), m. 220°, is <1/10 as potent a cumulative poison as ouabain although its acute toxic effects were as great in dogs and cats.

T. H. Rider

The antidotal action of sodium thiosulfate and dihydroxyacetone in cyanide poisoning, and the alleged antidotal action of glucose. B. B. Turner and H. R. Hulpieu. *J. Pharmacol.* 48, 445-69 (1933).—Dihydroxyacetone has a marked but fleeting antagonistic action to cyanide *in vivo* which serves to secure time for  $\text{Na}_2\text{S}_2\text{O}_3$ , a less rapid but better antidote, to take effect. Glucose is an ineffective antidote for CN in rabbits.

T. H. Rider

Phosphate-buffered injection medium disturbance in caffeine effects on voluntary muscle response. Ralph H. Cheney. *J. Pharmacol.* 48, 470-7 (1933).—Phosphate buffers produce an independent effect which render them unsuitable as solvents for studies of caffeine effects.

T. H. Rider

Toxicity and deposition of thallium in certain game birds. Paul A. Shaw. *J. Pharmacol.* 48, 478-87 (1933).—Tl kills game birds in doses of 12-30 mg. per kg. Muscular tissues acquire a higher concn greater than that administered, the vital organs and bone an equal concn and fat practically none. From 33 to 71% of administered Tl is retained until death 13 days after administration of 20 mg. per kg. to a goose. Poisoned game would probably be innocuous if consumed by men. In dogs 61.6% of the dose of Tl is excreted in the urine in 38 days at diminishing rates, so that at least 80 days longer would be required for complete excretion.

T. H. Rider

Narcotic agency in the paraldehyde series. P. K.

Knöfel. *J. Pharmacol.* 48, 488-91 (1933).—Isomers of  $\text{R}-\text{CH}(\text{O})-\text{CH}(\text{R})-\text{O}-\text{CH}(\text{R})$ , in which R is H,  $\text{CH}_3$

$\text{C}_2\text{H}_5$ , N- (I) or iso- (II)  $\text{C}_3\text{H}_7$  were administered to rabbits by stomach tube. Only *p*-acetaldehyde was suitable as a narcotic agent. I, b. 102°, has  $d_{20}^{25}$  0.9251 and is insol. in water. II m. 80° and is insol. in water.

T. H. Rider

The physiological action of the principles isolated from the secretion of *Bufo arenarum*. K. K. Chen, H. Jensen and A. L. Chen. *J. Pharmacol.* 49, 1-13 (1933).—From the secretion of *Bufo arenarum* were isolated cholesterol (no ergosterol), *areno-bufagin* (I) ( $\text{C}_{28}\text{H}_{48}\text{O}_6$ ), m. 220° (corr.) (colorless prisms from  $\text{EtOAc}$ ), *areno-bufotoxin* (II), ( $\text{C}_{28}\text{H}_{48}\text{O}_{11}\text{N}_4$ ), m. 194-5° (corr.) (colorless spheroids) which appears to be composed of 1 mol. of I combined with 1 mol. of suberyl-arginine, a red *areno-bufotenine* A, *flavinate* (III), ( $\text{C}_{12}\text{H}_{18}\text{O}_2\text{N}_2 \cdot \text{C}_{10}\text{H}_8\text{O}_2\text{N}_2\text{S}$ ), m. 130-1° (corr.) and a white *areno-bufotenine* B, *flavinate* (IV), ( $\text{C}_{12}\text{H}_{18}\text{O}_2\text{N}_2 \cdot \text{C}_{10}\text{H}_8\text{O}_2\text{N}_2\text{S}$ ), m. 285° (corr.), an indole deriv. and probably adrenalinic. I and II have digitalis-like actions, pressor actions and a stimulating effect on isolated rabbit intestines and guinea-pig uteri. The emetic dose of I in cats is 0.06 mg. per kg. and in pigeons 0.15 mg. per kg. The fatal dose of I in cats is 0.09 mg. per kg. The emetic dose of II in pigeons is 0.2 mg. per kg. and in cats is 0.15 mg. per kg. The fatal dose of II in cats is 0.41 mg. per kg. III has a slight pressor action, increases cardiac tone, and stimulates isolated rabbit intestine and guinea-pig uterus. IV stimulates isolated guinea-pig uterus.

T. H. Rider

The physiological action of the principles isolated from the secretion of the European green toad (*Bufo viridis viridis*). K. K. Chen, H. Jensen and A. L. Chen. *J. Pharmacol.* 49, 14-25 (1933); cf. C. A. 27, 4313. —From the secretion of *Bufo viridis viridis* were isolated cholesterol contg. 3% ergosterol, *virido-bufagin* (I) ( $\text{C}_{28}\text{H}_{48}\text{O}_6$ ), m. 255-55° (corr.) (from alc.) (*1*-diacetyl deriv., m. 253-4° (corr.)), *virido-bufotoxin* (II), ( $\text{C}_{28}\text{H}_{48}\text{O}_{10}\text{N}_4$ ) m. 198-9° (corr.), contg. arginine (pos. Sakaguchi test), *virido-bufotenine* A, *flavinate* (III) ( $\text{C}_{12}\text{H}_{18}\text{O}_2\text{N}_2 \cdot \text{C}_{10}\text{H}_8\text{O}_2\text{N}_2\text{S}$ ), orange needles, m. 170° (corr.), and *virido-bufotenine* B, *flavinate* IV, ( $\text{C}_{12}\text{H}_{18}\text{O}_2\text{N}_2 \cdot \text{C}_{10}\text{H}_8\text{O}_2\text{N}_2\text{S}$ ), red crystals, m. 131-2°, probably identical with *areno-bufotenine* A, *flavinate*. I has a digitalis-like action; min. emetic dose 0.15 mg. per kg. (pigeons), 0.27 mg. per kg. (cat); min. fatal dose 0.11 mg. per kg. (cats). II has actions similar to those of I; min. emetic dose 0.2 mg. per kg. (pigeons), 0.15 mg. per kg. (cats); min. fatal dose 0.27 mg. per kg. (cats). III and IV have pressor activity, increase heart tone and stimulate smooth muscle organs.

T. H. Rider

The physiological action of the principles isolated from the secretion of the Japanese toad (*Bufo formosus*). K. K. Chen, H. Jensen and A. L. Chen. *J. Pharmacol.* 49, 26-35 (1933). —From the secretion of *Bufo formosus* were isolated cholesterol, little if any ergosterol, *gama-bufagin* (I) ( $\text{C}_{28}\text{H}_{48}\text{O}_6$ ), m. 253-4° (corr.) (probably identical with *areno-bufotenine* A and *areno-bufotenin*), *gama-bufotoxin* (II) ( $\text{C}_{28}\text{H}_{48}\text{O}_{11}\text{N}_4$ ), m. 146° (indeterminate) (spheroids from alc.), *gama-bufotenine flavinate* (III), ( $\text{C}_{12}\text{H}_{18}\text{O}_2\text{N}_2 \cdot \text{C}_{10}\text{H}_8\text{O}_2\text{N}_2\text{S}$ ), m. 186-7° (corr.) (orange crystals from water), an indole deriv. I and II have digitalis-like actions; min. emetic doses in mg. per kg. cats I, 0.07, II, 0.175, pigeons I, 0.15, II, 0.20; min. lethal doses, mg. per kg. in cats I, 0.1, II, 0.38. III, has pressor activity, increases cardiac tone and stimulates intestines and uteri. Evidence is presented for the presence of adrenalinic.

T. H. Rider

The tranquilizing and respiratory depressant effects of tribromethanol (avertin), amylene hydrate, isoamyl-ethylbarbituric acid (amytal) and ethyl-(-1-methylbutyl) barbiturate (pentobarbital) alone and in combination with morphine on the rat. O. W. Barlow and Joseph D. Gludhill. *J. Pharmacol.* 49, 36-49 (1933).—The effects of morphine (I), avertin crystals (II), amylene hydrate (III), avertin fluid (IV), Na-amytal (V), and Na-penta-

barbital (VI) were studied alone and (I) in combination with each of the others. The minimal doses (mg. per kg.) producing complete tranquilization, the percentage of the M.L.D. which this dose represents and the attendant respiratory depression in percentage are, resp.: I, 21, 5.0, 30-5; II, 275, 37.5, 25; III, 1100, 78.5, 75; IV, 680, 47.0, 46; V, 98, 60.0, 70; VI, 36, 30.0, 40. Potentiation of II, IV, V and VI by I was evident both for tranquilization (order VI > II > V) and respiratory depression (order II > VI). There was no potentiation of respiratory depression of V by I, but the effect of V alone was equiv. to the other potentiated depression. T. H. R.

The influence of morphine on the premedication value of tribromoethanol (avertin) and tribromoethanol fluid (avertin fluid) in relation to nitrous oxide anesthesia in the rat. O. W. Barlow and James T. Duncan. *J. Pharmacol.* 49, 50-9(1933).—There is potentiation between morphine and avertin (I) in their premedicant effects. I is stronger than I-fluid subcutaneously; the 2 are about equal rectally although I-fluid has a more prolonged effect. These differences are probably due to differences in the ratio of absorption. Respiratory depression is pronounced with I. T. H. Rider

The influence of morphine on the premedication value of ethyl-(1-methylbutyl)barbiturate (pentobarbital) and isoamylethylbarbituric acid (amylal). O. W. Barlow and James T. Duncan. *J. Pharmacol.* 49, 60-6(1933).—The preanesthetic values of pentobarbital (I) and amylal (II) differ only quantitatively. I is approx. 2 times as active as II and has a wider margin of safety. Morphine (III) and I synergize. III potentiates II only within a narrow range of doses. T. H. Rider

The effect of calcium on the action of cocaine. Wm. Salant and Wm. M. Parkins. *J. Pharmacol.* 49, 67-77 (1933).—Cocaine (I) has little effect on intestinal motility of cats when injected intravenously, but with low Ca, I stimulates and with higher Ca, I depresses the intestine. Reduction of blood Ca decreases or reverses pressor effects of I and causes a depressant action on the circulation by I. Respiratory depression by I was decreased by lowering the blood Ca. T. H. Rider

The pharmacologic action of the phosphorous acid esters of the phenols. Maurice I. Smith, R. D. Lillie, E. Elvove and E. F. Stohman. *J. Pharmacol.* 49, 78-99 (1933); cf. Smith, Engel & Stohman, *C. A.* 27, 3253. T. H. Rider

The acute degenerative changes and the changes of recuperation occurring in the liver from the use of ethyl alcohol. A functional and pathological study. Wm. DeB. MacNider. *J. Pharmacol.* 49, 100-16(1933). T. H. Rider

The action of sodium oxalate in normal and thyroparathyroidectomized cats. Wm. Salant and Wm. M. Parkins. *J. Pharmacol.* 49, 117-32(1933).—Oxalate (I) injected intravenously in small doses in cats increased intestinal movements and produced fall or slight rise in blood pressure. After vagotomy or atropine I was without effect on intestines and distinctly pressor. In large doses, I caused inhibition of intestine and depression of circulation. After ergotamine which diminishes the irritability of sympathetic fibers, large doses of I stimulated the intestine, probably because of action on the parasympathetic. Respiration was stimulated by medium and depressed by large amts. of I. In thyroparathyroidectomized cats the resistance to oxalates was much greater than in normal cats. T. H. Rider

The antidotal action of picrotoxin, strychnine and cocaine in acute intoxication by the barbiturates. A. H. Maloney. *J. Pharmacol.* 49, 133-40(1933).—Picrotoxin is superior to either strychnine or cocaine as an antidote to 11 typical barbiturates. T. H. Rider

Actions of dinitrophenol. Repeated administration, antidotes, fatal doses, antiseptic tests and actions of some other isomers. M. L. Tainter and W. C. Cutting. *J. Pharmacol.* 49, 187-208(1933).—Repeated administration of 2,4-dinitrophenol (I) to dogs by various routes shows no tolerance in 2-3 months. Studies of urine, van den

Bergh tests and icteric indices failed to show toxic reactions and no pathol. alterations were noted except perhaps in the spleen. Fatal doses (80% mortality) in mg. per kg. were, rats, subcutaneous 25; dogs, subcutaneous 22, intramuscularly 20, intravenously 20, orally 20-30; rabbits, subcutaneously 30; pigeons intramuscularly 7. No drug antidotes were found. Other nitrophenols did not exert comparable results. I had no antiseptic action. T. H. Rider

The action of cocaine on the intestine. Frederick Bernheim. *J. Pharmacol.* 49, 209-14(1933).—Cocaine (I) from 0.1 to 0.2% relaxes guinea-pig ileum previously contracted by histamine, pilocarpine or Ba. The actions of I and nicotine are additive. T. H. Rider

The seat of the emetic action of pilocarpine. Nathaniel T. Kwit and Robt. A. Hatcher. *J. Pharmacol.* 49, 215-28 (1933).—Pilocarpine, in intravenous doses of 2 mg., produces vomiting in the cat and dog through peripheral action on the parasympathetic type of afferent nerve endings which transmit impulses to the center mainly through the sympathetic trunk. Atropine abolishes this action by its direct depressant action on the same nerve endings. T. H. Rider

Effects of posterior-lobe pituitary extract upon the serum and urine of normal dogs. A. R. McIntyre and R. F. Sievers. *J. Pharmacol.* 49, 229-36(1933).—

Posterior-lobe pituitary ext. (I) in doses of 0.75-2.0 units to a dog does not change the Na:K ratio in the serum, does not uniformly affect serum-Ca and raises the CuSO<sub>4</sub>-reducing power of serum in fasting animals. In the urine Na, K and Ca are increased and the Na:K ratio is decreased; the CuSO<sub>4</sub>-reducing power of urine is decreased. T. H. Rider

The site of the antidiuretic action of pituitary extract. W. W. Burgess, H. M. Harvey and H. K. Marshall, Jr., *J. Pharmacol.* 49, 237-49(1933).—The antidiuretic action of pituitary ext. in man is probably due to a stimulation of water reabsorption by the thin segment of the loop of Henle. T. H. Rider

The action of diuretics upon the glomerular kidney. Raymond N. Bieter. *J. Pharmacol.* 49, 250-6(1933).—The chlorides of Li, Na, K and Rb produce progressively increasing diuresis with increase of mol. wt. The chlorides of Mg, Ca, Sr and H<sub>2</sub> produce a progressively decreasing diuresis with increase of mol. wt. NaI and KBr produce results identical with those of the corresponding chlorides. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, NH<sub>4</sub>Cl and creatinine are also diuretic for the glomerular kidney. T. H. Rider

Tribromoethanol (Collatz) 7. Substituted quinoline-4-carboxylic acids (Benary) 10. Optical isomerism and blood-pressure-lowering action (v. Braun, Jacob) 10. Effect of unsatd. aliphatic groups in barbituric acids (Shonle, Waldo) 10. Piperidine derivs. (Walters, McElvain) 10.

## 1—ZOOLOGY

R. A. GORTNER

Physiology of the stink glands of the millipede, *Thyropygus malayus*. M. B. Lal. *Current Sci.* 2, 98-9(1933).—Both Cl<sub>2</sub> and HCN (approx. N/18000) were detected in the stink glands of *Thyropygus malayus*. R. B.

The occurrence of betaines in *Archa muscels*. Fr. Kutscher and D. Ackermann. *Z. physiol. Chem.* 221, 33-9(1933); cf. *C. A.* 26, 1003.—The filtrate from the AgNO<sub>3</sub>-Ba(OH)<sub>2</sub> ppt. (araine and other bases) from the ext. of *Archa noae* was converted into the so-called lysine fraction by means of phosphotungstic acid. This fraction contained the majority of the naturally occurring betaines. Glycine betaine was present in great preponderance. Smaller amts. of γ-butyrobetaine, carnitine and stachydrine were isolated and identified, and finally an isomer of trigonelline. Not only plants but also animal organisms have the power of methylating amino acids. A. W. Dox

Trimethylamine oxide and other nitrogen bases in crab muscles. F. A. Hoppe-Seyler. *Z. physiol. Chem.*

221, 45-50(1933).—The tail muscles of lobsters contain about 0.3% and those of river crabs about 0.05% of  $\text{Me}_2\text{NO}$ . The latter is the first reported occurrence of  $\text{Me}_2\text{NO}$  in fresh-water animals.  $\text{Me}_2\text{N}$  is also present in lobster muscle and imparts the characteristic taste and odor. Other bases identified are  $\delta$ -arginine, betaine, choline and an isomer of trigonelline.

Astacin from the eggs of the spider crab (*Maja squinado*). I. Richard Kuhn, Edgar Lederer and Adam Deutsch. *Z. physiol. Chem.* 220, 226-35(1933).—Vitellosin, one of the 2 pigments in the red eggs of the spider crab, was isolated in red crystals, m. 242-3° (decompn.). It was identified as an ester of astacin  $\text{C}_{27}\text{H}_{42}\text{O}_8$ , m. 241-2° (decompn.), the pigment of lobster eggs. Astacin is a highly unsat'd. hydroxylactone which forms a black-violet *Ac deriv.*, m. 235° (decompn.). Vitello-lutein, the 2nd pigment of spider crab eggs, is identical with  $\beta$ -carotene.

Effect of adrenaline on the structure of the hepatic cells of the turtle, *Cistudo europaea*. V. G. Radu. *Compt. rend. soc. biol.* 114, 72-4(1933).

Preliminary results of experiments made with electromagnetic waves ( $\lambda = 1 \text{ m.}$ ) on eggs of sea urchins. Carlo Maxia and Antonio Grimaldi. *Boll. soc. ital. biol. sper.* 8, 505-7(1933).—Electromagnetic waves ( $\lambda = 1 \text{ m.}$ ) acting on fertilized eggs of *Paracentrotus lividus* accelerate the development of the gastrula and plutei phases. The acceleration is not due to the development of heat by the waves.

A specific function of glucolysis in the morphogenetic processes of sea-urchin eggs. S. Tchakhotine. *Boll. soc. ital. biol. sper.* 8, 623-6(1933).—The glucolysis of sea-urchin eggs can be arrested by immersing them in solns. of  $\text{CH}_3\text{BrCOONa}$  (0.01  $M$  0.001  $M$ ). This produces a specific effect, consisting in the suppression of the development of the endoderm, and in the stimulation or excessive atypical development of the mesenchyme.

Spermatozoan movements and hydrogen-ion concentration. Experiments with the sperm of the rainbow trout. W. Schlenk, Jr. *Biochem. Z.* 265, 29-35(1933).—Movement of trout sperm is det'd. by the H-ion concn., change from  $p_H$  7.8 to 8.0 being sufficient to mobilize inactive sperm. Dilin. of the sperm fluid with ordinary water brings about this change. Dist'd.  $\text{H}_2\text{O}$  dissolves sufficient alkali from glass slides (but not from quartz slides) to cause mobilization.

Experimental investigations on the glycogen metabolism of the organization center in the amphibian

gastrula. I. Chr. P. Raven. *Proc. Acad. Sci. Amsterdam* 36, 566-9(1933).—*Axolotl* gastrula were studied. The disappearance of glycogen is intimately connected with invagination, and is probably either the cause or the result of it.

Supernumerary siphons and ocelli of *Ciona intestinalis* L. Konstantin von Haffner. *Z. wiss. Zool.* 143, 16-52(1933).—Largely zoological dealing with proliferation or regeneration of the oral or cloacal siphon of *Ciona intestinalis*. The presence of excess food material is not necessary for regeneration, since the state of nutrition of the animal has little effect.

Studies on the biology of caprellids. II. Space orientation, color adaptation and color change. A. Wetzel. *Z. wiss. Zool.* 143, 78-125(1933).—*Caprella dentata* is negatively phototactic to direct sunlight, but in diffuse light it becomes orientated at the edge of the shadow. The bulk of the light sensitivity is located in the eyes but the skin is somewhat sensitive. In colored light the various colored chromatophores broaden, each in its own color and independent of the light intensity. The green and red varieties of the animal are due to pigment not contained in chromatophores but diffused in the skin, and readily lost, in response to stimulus of the opposite color.

Blastocyte studies. I. The origin of the regeneration material in the division zone of *Dero limosa* Leidy and the problem of the activation of these cells. Haus-Adam Stolte. *Z. wiss. Zool.* 143, 150-200(1933).—Largely morphological.

The realization of genes and consecutive adaptation. III. Osmotic researches on *Physcosoma lurco* Sel. and de Man from the mangrove swamps of the Sunda Islands. J. W. Harms and Otto Dragendorff. *Z. wiss. Zool.* 143, 263-322(1933).—*Physcosoma lurca* is a marine animal which has become adapted to the soil conditions in the upper slopes of swamps, where flooding is only occasional; correspondingly the osmotic pressure of its body fluids was found to be approx. const. at about 1  $M$ , and partly independent of the osmotic pressure of the soil soln. However, on keeping in fresh water their osmotic pressure fell to 0.3  $M$ . A similarly adapted Echiuroid showed similar changes. The evolutionary process from sea to land habitat probably goes through a stage in which the animals are passively variable in osmotic pressure, following changes in the surrounding fluid.

Tetrahydroxybutofostan from the winter bile of toads (Makino) 10.

## 12—FOODS

F. C. BLANCK AND H. A. LEPFER

Food legislation and patent law. E. Merres. *Angew. Chem.* 46, 651-2(1933).—A discussion of the relation between food legislation and patent law with 26 references.

Air-conditioning in food factories. Osman Jones. *Food* 3, 7-8(1933).—A brief discussion of its benefits.

The microscopy of food products. I. Applicability and limitations. Charles H. Butcher. *Food* 3, 11-12(1933).—A brief discussion.

Painting in food factories. Albert E. Robinson. *Food* 3, 18-20(1933).—A brief discussion of the benefit of painting, more particularly in the case of Al paints.

Canning of dry materials in vacuo and in inert atmospheres. H. Wentworth Avis. *Food* 3, 45-6(1933).—A brief discussion.

Problems of heat transfer in canning. S. Lencefield. *Food* 3, 48-50(1933).—A brief discussion.

Preventing changes in stored frozen food. Donald K. Tressler. *Food Ind.* 5, 410, 432(1933).—Catalase may be used as an index of the activity of other enzymes in vegetables being prepd. for freezing preservation. A blanching period sufficient to destroy catalase insures de-

struction of other deteriorative enzymes during storage. Since fruits cannot be heated, they are best packaged in compact moisture-vapor-proof materials which largely prevent desiccation and oxidation. The addn. of sugar also has a protective action. Except for the oxidation of the fat, enzymic action in frozen meats is beneficial and increases tenderness. However, enzymic changes in fish are objectionable in that they produce offensive odors, and may increase leakage. The presence of Ca and Mg salts in the salt used in prepg. brines is likewise very objectionable.

Changes which may occur in frozen foods during cold storage. D. K. Tressler. *Food Ind.* 5, 346-7(1933).—A general discussion of deteriorative changes in frozen foods due to enzymes, oxidation, hydrolysis and coagulation. Desiccation of such products as poultry and fish is also the cause of serious losses unless controlled.

Enzymes can cause off-flavors even when foods are frozen. H. C. Diehl, J. H. Dingle and J. A. Berry. *Food Ind.* 5, 300-1(1933).—Alderman peas, asparagus, spinach, lima beans and snap beans after storage at freezing temps. for 4-6 weeks acquire undesirable flavors

and odors which are accentuated by cooking. In general, a scalding process sufficient to destroy catalase prevented the enzymic deterioration of frozen peas. Min scalding periods were 30 sec at 100°, 50 sec at 88° or 105 sec at 74°. Rapid cooling of the vegetables after scalding is recommended as an aid to preserving quality. Catalase serves as a useful index to the destruction by heat of other enzymes in fresh vegetables. C. R. Fellers.

**Diastases. General notions and applications in the food industry.** M. Javille. *Bull. soc. sci. hyg. aliment.* 21, 224-53 (1933). Two lectures. A. P. C.

**Present status and development of collective feeding in the U. S. S. R.** B. Shal'ky. *Bull. soc. sci. hyg. aliment.* 21, 251-65 (1933). A. Papineau-Couture.

**Food poisoning in Puerto Rico.** O. Costa Mundry. *Puerto Rico J. Pub. Health Trop. Med.* 9, 14-68 (1933). J. A. Kennedy.

**Bibliography on heavy metals in food and biological material.** X. Bismuth. *Ann. Analyst.* 58, 607-8 (1933). The bibliography contains the titles of 4 papers published since 1921. Brief comments are made concerning the scope of many of these papers. W. I. H.

**Report on the determination of arsenic in foods.** W. C. Ashby Jones. *J. Assoc. Official Agr. Chem.* 16, 325-9 (1933). In the third line of the title in C. I. 27, 517 read the latter, instead of the former, showing that the bromate method gave better results than the Gutzeit methods. A. Papineau-Couture.

**Lactose (milk sugar) becomes a food.** Frederick M. Greenleaf. *J. Food Ind.* 5, 301-6 (1933). Lactose is about 1% as sweet as sucrose, dissolves readily and has a pleasant taste. It is non-hygroscopic. The substance supports the normal putrefactive microflora of the colon and stimulates the growth of the acid-forming lactobacilli. C. R. Fellers.

**Report of the Subcommittee on Selenium as a Kjeldahl Catalyst in the Cereal Laboratory.** C. I. Davis and M. Wise. *Cereal Chem.* 10, 488-9 (1933). A. Kjeldahl catalyst does not appear to be a universally applicable to general titration conditions. It does, however, in combination with common catalysts, especially Hg, is to be discouraged. I. H. Bailey.

**An evaluation of systematic and random errors in protein moisture and ash determinations.** Alvin L. Tisdale. *Cereal Chem.* 10, 47-57 (1933). I. H. Bailey.

**Report on (the analysis of) cereal foods.** J. A. Leckie. *J. Assoc. Official Agr. Chem.* 16, 432-1933. Cf. C. I. 27, 141. A brief review of progress accomplished in 1933 is shown by the reports of the associate referees of following abstracts. A. Papineau-Couture.

**Report on (the determination of) hydrogen ion concentration of flour.** Rowland J. Clark. *J. Assoc. Official Agr. Chem.* 16, 393-7 (1933). A collaborative comparison of the electrometric and colorimetric determination of the H-ion content of flour with the A. O. A. C. method for the purpose of the test, showed remarkably close agreement between the two methods, particularly in view of the fact that different standard procedures were used by the various collaborators. A. Papineau-Couture.

**Report on (the determination of) the diastatic value of flour.** M. J. Ellis. *J. Assoc. Official Agr. Chem.* 16, 19-50 (1933). Cf. C. I. 27, 142. For all practical purposes it is unnecessary to run a blank determination of the diastatic activity of flour by the Rumsey type of method. Collaborative study of the previously described method yielded uniformly satisfactory results, though in some cases there was an increase particularly in view of the nature of the flour. Possible ways of improving the method are discussed. A detailed description is given of the technique of adaptation to the determination of maltose in small quantities of flour extracts of Hagdorn and Jensen's micro method for the determination of blood sugar (C. I. 17, 2721). The merits of the method are pointed out. It will be studied collaboratively. A. Papineau-Couture.

**Report on (the determination of) starch in flour.** H. Evelyn Jones. *J. Assoc. Official Agr. Chem.* 16, 501-5 (1933). Cf. C. I. 27, 142. The technique of the tentative A. O. A. C. method (Rask method) has been modified by

1 minutely specifying the conditions of hydrolysis of the starch by HCl, of precipitation of the starch and of its filtration, so as to overcome the previously noted difficulties encountered in filtration. It was compared collaboratively with the Hartmann-Hillig diastase-acid hydrolysis method (C. A. 25, 1941). Results indicated that the modified Rask method should readily give good results in the hands of analysts having experience with it, the Hartmann-Hillig method is complicated, time-consuming, offers considerable chances for errors, and gives higher results than the modified Rask method. A. P. C.

**Report on (the determination of) flour-bleaching chemicals.** Dorothy B. Scott. *J. Assoc. Official Agr. Chem.* 16, 508-10 (1933). Cf. C. A. 27, 142. Spencer's suggestion that  $\text{NH}_4\text{HCO}_3$  or  $\text{NaHCO}_3$  be used in the Seidenberg method for the determination of Cl in Cl-bleached flour is unnecessary if precaution is taken to use a small yellow flame of a Bunsen burner. High blanks were always obtained in the Seidenberg method, the greater portion of which probably comes from the  $\text{Na}_2\text{S}_2\text{O}_3$ . The 3 main difficulties of the Seidenberg method (length of time required, high blanks, difficult end point) are avoided by using the present A. O. A. C. Tentative Method II (Rask method) with final titration of the Cl by the Volhard method. A. Papineau-Couture.

**Report on (the determination of) carbon dioxide in self rising flours.** I. D. Whiting. *J. Assoc. Official Agr. Chem.* 16, 511-12 (1933). Cf. C. I. 27, 142. It is suggested it may be feasible to determine a factor which could be applied to the results of the gasometric determination of  $\text{CO}_2$  in self rising flours to give figures in close agreement with the theoretical  $\text{CO}_2$  content. A. P. C.

**Report on (the estimation of) rye in flour mixtures.** J. H. Bornmann. *J. Assoc. Official Agr. Chem.* 16, 520-5 (1933). Cf. C. I. 27, 143. The methods which have been proposed for the detection or estimation of wheat and rye in presence of each other are briefly critically reviewed from the regulatory standpoint of distinguishing between accidental and intentional addition of either to the other (10% wheat in rye or 7% rye in wheat are permissible as accidental additions). The  $\text{CHCl}_3$  test (Benedek, *Landw. Ver. Sta.* 36, 337 (1889)) and the Koenig and Busch method (C. I. 18, 1721) and the Strolacker modification (C. I. 27, 1680) of Lilman's method are considered most worthy of further consideration, the first 2 being applicable only to flour and the 3rd to bread also. A. Papineau-Couture.

**Report on experimental baking tests.** C. G. Hurd. *J. Assoc. Official Agr. Chem.* 16, 525-6 (1933). Cf. Hurd, C. I. 27, 143. It is recommended that the directions recommended to the Association of Cereal Chemists by Merritt Blish and Sundt (C. I. 26, 3543) with some reservations that are noted, be adopted by the Association of Agr. Chemists. A. P. C.

**Report on (the determination of) crude fiber in alimentary pastes, bread and baked products.** R. G. Capen. *J. Assoc. Official Agr. Chem.* 16, 518-19 (1933). The official Association of Agr. Chemists method for crude fiber in grain and stock feeds is recommended for adoption as official for bread and alimentary pastes, its application to baked products will be further studied. A. Papineau-Couture.

**Report on sampling and determination of moisture in alimentary paste, bread and baked products.** L. H. Bailey. *J. Assoc. Official Agr. Chem.* 16, 512-3 (1933). Cf. C. A. 27, 143. Collaborative study showed that concordant results may be obtained by using either the vacuum oven and the 130° air oven methods. A. Papineau-Couture.

**Report on (the determination of) fat by acid hydrolysis, total phosphorus ( $\text{P}_2\text{O}_5$ ), lipoids and lipid phosphorus ( $\text{P}_2\text{O}_5$ ), and water soluble nitrogen precipitable by 40% alcohol in flour, bread and alimentary pastes.** Lloyd C. Mitchell. *J. Assoc. Official Agr. Chem.* 16, 514-18 (1933). Cf. C. I. 27, 5120. Bornmann (C. I. 27, 143). In the determination of fat, acid hydrolysis at the temperature of boiling water is necessary in the analysis of cereals, causes considerable churning, and gives high results, a temperature of 70° is too

high to ensure concordant results in the hands of different analysts; at 48-50° there is no charring, but the temp. seems too low to ensure complete removal of the fat by  $\text{Et}_2\text{O}$ -petr. ether. The method for the detn. of  $\text{P}_2\text{O}_5$  in eggs seems satisfactory for its detn. in flour, baked products and alimentary pastes, provided the temp. is raised to 700° instead of 500°. For the detn. of lipoids and lipid  $\text{P}_2\text{O}_5$ , promising results have been obtained by applying the  $\text{CHCl}_3$ -alc. extn. method to the sample after addn. of sufficient water to form a dough. A. P.-C.

• Report on (the determination of) milk solids in milk bread. Arnold Johnson. *J. Assoc. Official Agr. Chem.* 16, 519-20(1933).—Two different types of methods have given promising results: (1) extn. of casein with a 79-30  $\text{C}_2\text{H}_5\text{N}-\text{H}_2\text{O}$  mixt., reprecipn. of the casein from the ext. either by adding 2 vols.  $\text{C}_2\text{H}_5\text{N}$  or by adding  $\text{HCl}$  to  $\text{pH}$  4.0-4.7, and detn. of N in the ppt.; (2) extn. with  $\text{H}_2\text{O}$ , fermentation of non-lactose sugars by means of yeast, defeating by Rumney's phosphotungstate method (C. A. 17, 597), reducing by Quasimoff and Thomas' method (C. A. 16, 37), and detg. reduced Cu by Shaffer and Hartmann's method (C. A. 15, 1327-8). A. P.-C.

• Report of the Subcommittee on the Viscosity Test for Soft Winter Wheat Flours E. G. Bayfield. (*Cereal Chem.* 10, 494-50(1933)) L. H. Bailey

Bean flour and malt flour in milling and baking P. Bruère and J. Chevalier. *Ann. fals.* 26, 464-9(1933).—The improvement of wheat flour by addn. of small quantities of bean or malt flours is not attributable to their proteins, but merely to their amylolytic and proteolytic enzymes and to the chem. transformations which they accelerate. Optimum results are obtained with 0.5-1% of bean or malt, and greater amts. have a detrimental effect on the mech. properties of the flour. A. P.-C.

Biochemical characteristics of dough and bread from sprouted grain Natalie Kozmin. *Cereal Chem.* 10, 120-36(1933).—The fundamental difference between bread baked from sprouted wheat flour as compared with normal flour consists of a sharp increase of water-sol. substances in the former, namely, reducing sugars and dextrans, with a predominance of the latter. The direct cause of the defectiveness of the crumb of bread made from sprouted wheat flour is an excessive splitting of the starch. The amt. of the latter decreases so much that there is not enough left for holding together all the water present in the dough by gelatinization in the baking process, and the crumb appears wet and sticky, not because there is too much water in it, but because this water is not held together sufficiently by the gel of the starch and forms with the sugars and dextrans a sticky mass. By acidifying a dough in the proper manner the starch splitting by enzymes may be greatly inhibited. A dough made with 0.1 N  $\text{HCl}$  instead of water ferments in a natural way (yeast is added after the greater portion of the acid is bound with the protein of the dough) and is capable of producing a normal loaf, slightly more sour in taste. The crumb of the bread is quite normal, dry and elastic. The content of the water-sol. substances falls off, sharply approaching the characteristics of a control loaf. L. H. Bailey

The measurement of color in flour and bread by means of Maxwell disks J. C. Baker, H. K. Parker and F. B. Freese (*Cereal Chem.* 10, 437-46(1933)). The N-A colorimeter and equipment are illustrated and described. The instrument is used primarily in confirming and maintaining mill standards, analyzing what is wrong with a flour color, selecting those grades which have a certain characteristic in the flour streams and for specifying flour color. L. H. Bailey

The influence of humidity and carbon dioxide upon the development of molds on bread. Oscar Skovholt and L. H. Bailey. *Cereal Chem.* 10, 446-51(1933).—Relative humidities of about 90% or more in the environment are required to permit appreciable mold development on bread crust within the usual interval of time between production and consumption. Bread crumb is more hygroscopic than bread crust. The introduction of milk solids into bread slightly increases the hygroscopicity of both crust and crumb.  $\text{CO}_2$  concns. of 17%

will retard, and if as high as 50% will prevent, mold growth on bread, but only while maintained in such atmos. L. H. Bailey

Use of pure yeast cultures and lactic organisms in fermenting rye flour dough. N. V. Palladin, A. I. Kdraseva and E. K. Kresling. *Schriften zentral biochem. Forschungsinst. Nahr.-Genussmittelind.* (U. S. S. R.) 1, 300-40(1932).—From a comprehensive study of the use of lactic acid bacteria in making rye bread, it is concluded that lactic organisms alone cannot impart good flavor and aroma to rye dough even if several mixed strains are used. For fermentation of the dough to optimum acidity, porosity and flavor a pure yeast culture must be introduced to aid the lactic acid bacteria. Julian F. Smith

Report of the subcommittee on methods for chemical leavening agents. P. A. Collatz. *Cereal Chem.* 10, 501(1933). L. H. Bailey

Report on (the determination of) milk proteins. Marie I. Offutt. *J. Assoc. Official Agr. Chem.* 16, 489-91(1933).—Collaborative comparison of the official A. O. A. C. method and the method described by Waterman (C. A. 21, 2339; 25, 4942) showed satisfactory agreement between the 2. Fair agreement was obtained between the official method for albumin in milk and a method consisting essentially in removing casein as in Waterman's method for detg. casein, neutralizing the filtrate, adding 0.3 cc.  $\text{AcOH}$  (1 + 1), pptg. albumin by heating on the water bath, and calcg. the albumin content from the difference in the N content of the filtrate from the casein and in the filtrate from the albumin. A. P.-C.

The formaldehyde titration of milk proteins and its use in the detection of re-constituted creams, etc. J. C. Haral. *Analyst* 58, 605-6(1933).—The formaldehyde method as now carried out in England consists in adding 0.4 cc. of satd.  $\text{K}_2\text{C}_2\text{O}_4$  soln. to 10 cc. of milk and then titrating with 0.1 N  $\text{NaOH}$  soln. to a definite pink shade of phenolphthalein. Then 2 cc. of neutral formalin is added and the liberated acid is titrated again with  $\text{NaOH}$  until the original color is restored. A fairly close relation exists between the vol. of  $\text{NaOH}$  required for the formal titration and that corresponding to the total N in the same wt. of sample. In the analysis of 10 samples of milk, the ratio varied from 17.8 to 19.4 but with 8 milk powders the ratio ranged from 25.0 to 29.1. With natural cream the ratio was 19.2 whereas 2 samples of re-constituted milk showed the ratios 25.5 and 28.0, showing that they had evidently been prepd. from dried milk. W. T. H.

Note on the formaldehyde titration of milk protein, and its application to the estimation of caseinogen. Gerald I. Pyne. *Biochem. J.* 27, 915-17(1933), cf. C. A. 27, 144. The factor for converting formaldehyde titration values into milk protein shows a progressive increase throughout the lactation period, which appears to arise immediately from a similar but more marked increase in the whey protein factor and to be attributed largely to variations in the compn. of non-protein N. The formaldehyde titration can be used to est. casein. B. H.

Fermented milk from Sardinia. N. Baiardo and E. Lucchetti. *Ann. chim. applicata* 23, 396-401(1933).—The av. compn., method of manuf., and analytical methods for detecting adulteration of fermented milk in Sardinia are given. A. W. Contieri

Utilization of dairy wastes. T. Lakshman Rao. *Madras Agr. J.* 21, 388-91(1933).—The prepn. and uses of *casein* are discussed. K. D. Jacob

Tests for re-constituted cream. F. W. Richardson. *Analyst* 58, 686(1933).—When natural cream is shaken with a mixt. of benzene and 95%  $\text{MeOH}$  in equal vols. there is no sepn. into distinct layers, but with artificial cream layers are formed. About 20 turns of the centrifuge is often sufficient for the test. Pure acetone may be substituted for the benzene- $\text{MeOH}$  mixt. Take about 5 cc. of cream and an equal vol. of pure  $\text{Me}_2\text{CO}$  in a centrifuge tube and give it 100 vigorous spins, and at the same time treat a sample of pure cream in the same way. The test is not altogether reliable when the cream is turning sour. W. T. H.

**Chemical standardization of ice cream.** L. H. Lampitt and M. Bogod. *Chimie & industrie Special No.*, 1200-4 (June, 1933).—The method is based on the analysis of the unfrozen mix and addn. to the latter of an auxiliary mix (about 10% of the main mix), the compn. of which is calcd. from the analytical results to bring the compn. of the total mix to standard. Analysis comprises detn. of total solids (Mojonnier method), fat (Mojonnier modification of the Roesse-Gottlieb method) and sucrose (modification of the method of the Milk Products Subcommittee of the Soc. of Pub. Analysts, Hinks and Hughes, *C. A.* 24, 1905), and can be carried out in 35 min.

**Report on (the analysis of) ice cream.** G. G. Prary. *J. Assoc. Official Agr. Chem.* 16, 488 9(1933).—A preliminary study of the Illinois test (Overman and Garrett, *C. A.* 25, 1508) and of the Nebraska test (Crowe, *C. A.* 24, 5078) for detg. butter fat in ice cream by a modification of the Babcock test gave less favorable results than those reported by the initiators of the tests; they will be further studied collaboratively. A. P.-C.

**Report on (the analysis of) butter.** C. W. Harrison. *J. Assoc. Official Agr. Chem.* 16, 480 4(1933); cf. *C. A.* 27, 145.—A collaborative comparison of the present official A. O. A. C. method of prepg. butter samples for analysis and of a method using a mech. stirrer (of the malted-milk stirrer type) showed that both were equally satisfactory.

**The linoleic and linolenic acid contents of butter fat.** H. C. Eckstein. *J. Biol. Chem.* 103, 135 40(1933). The linoleic and linolenic acid contents of butter fat, representative of the product produced in Michigan, varied from 0.17 to 0.25 and from 0.07 to 0.17%, resp. These values are probably too low as poor recoveries were obtained when these acids were added to butter. The linolenic acid content can be increased by including linseed meal in the ration. The acid contents were calcd. from the wts. of cryst. bromide fraction. These results indicate why butter fat does not readily alleviate the condition caused by a prolonged fat-free dietary regime and are not in accord with the findings of Hilditch, *et al.* (*C. A.* 25, 152) who reported a linolenic acid content of as much as 4.5%.

**Isolation and identification of some hitherto unreported fatty acids in butter fat.** A. W. Bosworth and J. B. Brown. *J. Biol. Chem.* 103, 115 31(1933); cf. *C. A.* 25, 2776. Butter fat definitely contains decenoic ( $C_{10}H_{18}O_2$ ) and tetradecenoic ( $C_{14}H_{26}O_2$ ) acids, highly unsatd. acids of the arachidonic type, probably belonging to the  $C_{22}$  series, and a  $C_{20}$ , a  $C_{22}$  or a  $C_{24}$  acid with 2 double bonds. A mixt. has also been isolated contg. satd. acids consisting principally of tetracosanic (lignoceric) along with small amts. of behenic and erotic acids. Evidence for the occurrence of hexadecenoic (palmitoleic) and octadecenoic (gadoleic) acids was doubtful and all attempts to verify the presence of ordinary linoleic acid failed (cf. preceding abstr.). The Me esters of the fatty acids from a typical sample of creamery butter were efficiently fractionated into 37 fractions.

**Some further observations on factors which influence the component fatty acids of butter.** Harry K. Dean and Thomas P. Hilditch. *Biochem. J.* 27, 889 97(1933). One change is seasonal and consists in an abrupt increase in the proportion of oleic and linoleic acids, with a diminution in butyric and stearic acids, a change which occurs in each of the spring seasons when the cows return to pasture from indoor winter conditions. The other change, which is a function of the age of the cow, consists in a gradual augmentation of the amt. of unsatd. components of the fat over the whole period of years. B. H.

**Examination of authentic samples of butters from sheep and goat milk.** Th. G. Stathopoulos. *J. pharm. chim.* 18, 287 9(1933). Tabulated results on 16 samples show agreement with official Greek standards for cow butter, except that the Reichert-Meissl no. is lower (23.42-23.83 instead of 26). All these butters very strongly gave the Drummond-Watson test for vitamin A (cf. *C. A.* 16,

3934) even after considerable diln. with other fats free from this vitamin. S. Wafdhott

**Report on cheese. Determination of lactose and sucrose in process cheese.** Carl B. Stone. *J. Assoc. Official Agr. Chem.* 16, 484-7(1933).—A collaborative study of Huebner's method (*C. A.* 24, 3839) gave satisfactory results and showed that the method gives results very close to the theoretical and will recover added lactose and sucrose. A. Papineau-Couture

**Starters for cheese making: methods of preparation and maintenance.** G. M. Moir. *New Zealand J. Agr.* 47, 81-8, 143 9(1933). The chemistry, prepn., preservation and use of starters are discussed. Sixteen references.

**Study of the Schmid-Bondzynski method for the determination of fat in cheese.** Henry A. Lepper and Leslie Hurt. *J. Assoc. Official Agr. Chem.* 16, 584 9(1933).

A collaborative study of the method showed it gives concordant results in the hands of different analysts. A cheese sample in which the fat has become sepd. before analysis may be remixed and analyzed, if necessary, and the result obtained will be as satisfactory as if the fat had not sepd. A. Papineau-Couture

**The hen egg as a nourishing human food.** J. Grossfeld. *19th Ztg.* 48, 1189 91(1933). The relative values of the following foodstuffs: cow milk, Emmentaler cheese, beef, peas and wheat bread are compared with that of hen egg, from the standpoints of nourishment and cost. W. O. F.

**Report on (the determination of salt in) meat and meat products.** R. H. Kerr. *J. Assoc. Official Agr. Chem.* 16, 543 6(1933).—Four methods were studied collaboratively. (1) Ashing after addn. of  $Na_2CO_3$  soln., dissolving in 1 + 4  $HNO_3$  and titrating by the Volhard method. (2) Add a known amt. of 0.5  $N$   $AgNO_3$  (more than sufficient to ppt. all the Cl) and 15 cc. concd.  $HNO_3$ , boil till the meat is thoroughly disintegrated (about 10 min.), add 5%  $KMnO_4$  soln. in small successive portions till the soln. is practically colorless, add 25 cc.  $H_2O$ , boil 5 min., cool, dil to about 150 cc., shake with 25 cc.  $Et_2O$  to dissolve the sepd. fat, and titrate Cl by the Volhard method without sepn. of the  $Et_2O$  or filtration of the  $AgCl$ . (3) This method is the same as (2), except that  $HNO_3$  digestion is carried out on the steam bath overnight. (4) Digest 5 g. of sample with 300-350 cc.  $H_2O$  and 25 cc. concd.  $HNO_3$  on the steam bath for 3-4 hrs., heat to boiling, add 5%  $KMnO_4$  soln. in small successive portions to practical decolorization of the soln., cool, make to 500 cc., and titrate a 100-cc. aliquot by the Volhard method. Methods (1), (2) and (3) gave closely agreeing results; the results of method (4) indicated that heating with  $HNO_3$  involved a slight loss of Cl.

**Thermal properties of meat.** J. H. Awbery and Ezer Gulliths. *J. Soc. Chem. Ind.* 52, 326 8T(1933). Data are given of the specific heat, thermal cond. and thermal diffusivity of fresh beef. F. L. Dunlap

**Nutritional chemical investigation on porgy. II. The age of porgy and meat composition.** Mrs. Yasu Hata-koshi. *J. Chem. Soc. Japan* 54, 852 8(1933); cf. *C. A.* 27, 348. Analyses of 4, 5- and 7-year old porgies indicated that water, protein, ash content and  $pH$  value of the meat decreased with an increase of age while the fat content had a tendency to increase. The total N and amino N of the serum were const. The porgy proteins fluctuated slightly according to the difference in age but they were affected more by the difference of the season and sex. III. The sex of porgy and its meat composition. *Ibid.* 982-90. The meat from the male contained more water, protein, glycogen and ash and less fat throughout the season than that from the female. The water content was min. in both sexes before the propagating season; the protein and ash contents increased thereafter and then decreased gradually. There was no seasonal or sexual variation in  $pH$  value, total- and amino-N contents of the meat. K. Katsuta

**Oils used in the packing of fish.** J. Gangl. *Osterr. Chem.-Ztg.* 36, 119 53(1933). A study of methods for

the identification of oils used in the packing of fish. G. 1 concludes that despite the label that olive oil has been used in the packing of sardines produced in Portugal much use is being made of peanut oil. F. L. Dunlap

**Problems of the vegetable oil producers.** W. R. Woolrich and E. L. Carpenter. *Food Ind.* 5, 260-2(1933).—Mech. extn., chem. extn., and bacteriol. methods of vegetable oil production, particularly cottonseed oil, are discussed. The addn. of moisture to the seeds just before cooking, and bringing the seeds to a temp. of 89° with steam, materially reduces the extn. time. Cooking has several functions: it is a drying process, coagulates the proteins and facilitates filtration, breaks down the cells and allows the oil to escape, and lowers the viscosity of the oil. A cooking period of 10-20 min. is sufficient if the meats are kept at 110°. Above this temp. the oil darkens perceptibly. Most of the problems facing the industry are of a mech. rather than a chem. nature. C. R. Fellors

**Investigations on fruit products. I. Preparation of juices, sirups, concentrates and wines from some English fruits.** Vernon L. S. Charley. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 175 201.—Data are given on the compn. and characteristics of the products obtained from gooseberries, rhubarb, strawberries, red and black currants, raspberries, loganberries, blackberries and plums. **II. Enzymic clarification of fruit juices.** *Ibid.* 202-13.—The nature of the colloidal constituents in fruit juices and methods for their removal are discussed. Expts. on the use of a com. pectin-decomp. prepn. (Pectinol) as an aid to the clarification and filtration of fruit juices are reported. After the Pectinol treatment the juices were filtered through paper and lab. Seitz E. K. filters and were stored in sterile bottles. Excellent results were obtained on strawberry juice, but with juices of higher acidity, such as loganberry, raspberry and black currant, considerable fermentation occurred before any noticeable results of the enzyme were apparent. The best results were obtained with 1% of Pectinol. Enzyme action sometimes continued after filtration of juices through a Seitz filter, causing further deposits to form; this can be prevented by pasteurizing the juice at the enzyme inactivation temp. (131°F.). **III. Non-alcoholic apple juice.** *Ibid.* 214-31.—Various methods for the prepn. of nonale. apple juice are discussed. Filtration through a Seitz filter adversely affected the "body" and color of the juice, pasteurization caused "cooked" flavors in some juices. The use of Pectinol increased the clarity and loss of "body." The percentages of pectin were much greater in the pasteurized samples than in the corresponding Seitz-filtered material, and the Pectinol treatment caused further loss of pectin. A correlation between lack of flavor and loss of pectin is indicated. The type of treatment had no sp. effect on the acidity and the tannin content. K. D. Jacob

**Chemical study of tomato juice.** Charles F. Poe, Arthur P. Wyss and Truman G. McEver. *J. Assoc. Official Agr. Chem.* 16, 624 7(1933).—Analyses of lab.-prepd. juices from raw and cooked tomatoes, home-canned tomato juices and home-canned tomato juices contg. added salt are tabulated and briefly discussed. It is suggested that the detn. of total solids and insol. solids on the whole juice, and solids, H<sub>2</sub>O-sol. solids, ash, alky. of ash, immersion refractometer reading, volatile acids and reducing sugars on the serum would be suitable as a guide for detection of adulteration. A. P.-C.

**Estimation of water in tomato marc.** Clemens Grimme. *Pharm. Zentralhalle* 74, 641 2(1933).—An exptl. study of various methods shows that procedures based on distn. of the sample with xylene give too high, by sp. gr. too low, values; results which agree fairly well are obtained, however, by careful drying with sand at about 100°, by 4-hr. distn. with C<sub>2</sub>H<sub>6</sub> or 2-hr. distn. with PhMe. W. O. E.

**Ridding tomato pulp of black spots and grit.** C. M. Ambler. *Food Ind.* 5, 254(1933).—A super-centrifuge capable of delivering 500 gal. per min. of tomato pulp effectively removed dirt and carbonized particles of tomato. As much as 5 lb. of undesirable materials can

be removed from 600 gal. of pulp of apparently good quality. C. R. Fellors

**Chemistry in the dried fruits industry.** E. J. White-lock. *Chem. Eng. Mining Rev.* 25, 63 4(1933).—Various chem. dipping processes are used for lemons and sultanas depending on (1) the class of fresh fruit available, (2) the climate of the district and (3) the capacity of the drying plant. A mixed dip contg. 2 1/2 lb. (1.02 kg.) K<sub>2</sub>CO<sub>3</sub>, 1 1/2 pints (0.71 l.) olive oil and 1 1/2 lb. (0.7 kg.) NaOH is used. Dried fruit processes with the mixed dip approximate closely in color and type that from the cold dip, while a higher percentage of high-grade fruit is realized. The drying period, as compared with the cold dip, is shorter with a greater possibility of finishing off the fruit before bad weather occurs; the costs of the ingredients are much lower; the green tinge is more readily removed and the racks are released for a second filling earlier in the season with less deterioration of those grapes still on the vines. W. H. Boynton

**Chemical studies of frozen fruits.** J. G. Woodroof. *Ca. Agr. Expt. Sta., Ann. Rept.* 1932, 37 8(Summary); cf. C. A. 26, 4386; 27, 786.—The acidity of the expressed juices of fruits increases on freezing. Cond. detns. on salt and sugar solns. in which peaches and strawberries were immersed for varying periods indicated that 35% sugar solns. were most suitable for peaches and 60% for strawberries. Various concns. of CO<sub>2</sub>, N and air showed no beneficial effects on the keeping quality of peaches at 4-5°. Respiration studies showed that the gases in fresh fruits were not appreciably expelled by freezing but were slowly lost while the fruit was in the frozen state. Vacuum packing of fruit in sugar sirup caused greater penetration of the sirup into the tissue. C. R. F.

**How to control banana ripening.** C. F. Greeyes-Carpenter. *Food Ind.* 5, 341-2(1933).—Ripening is controlled by temp. and humidity. The optimum temp. is 17-20° and humidity 90-95%. When the fruit begins to color, the temp. is reduced to 19° and held there at a relative humidity of 80% to prevent over-ripening and shrinkage. Ripening fruit can be held in an almost static state at 13-14°. During ripening the starch content decreases from 26 to 1% and the sugar content increases from less than 1 to approx. 19.5%. C. R. F.

**Early potatoes with high solanine content.** Hans Valentin. *Pharm. Zentralhalle* 74, 611 14(1933).—Samples of the early potato "Vater Rhein" harvested in late September showed after examn. by 3 different methods (Schmiedeberg and Meier, Morgenstern, Börner and Mattis) unusually high solanine contents (442, 457 and 446 mg. per kg., resp.), while seed potatoes of the same strain and wintered over 1931, 1932 and 1933 yielded about 1/10 as much solanine. No satisfactory explanation is available for the high solanine content. W. O. E.

**Effect of the nature of the containers on the quality of canned goods.** M. A. Machobocuf, H. Cheftel and Mrie. J. Blass. *Ann. fals.* 26, 470-4(1933); cf. C. A. 26, 3042.—Spinach, green peas, beans and tomatoes were canned in Pyrex jars, in presence and absence of a sheet of tinplate, and in metal cans in presence and absence of a piece of ordinary glass. They were subjected to gustative tests at the end of about 1 yr. Conclusions: Overcooking, which can be more easily avoided in metal than in glass on account of the possibility of rapid cooling, always plays a certain part, very slight in most cases, but appreciable in the case of some products that are exceptionally delicate. The chem. effect of the container makes itself felt only after a fairly long time, appears to affect unfavorably the gustative qualities of the product, and is more pronounced with ordinary glass than with Pyrex. The effects of the chem. phenomena and of overcooking are additive, and in certain cases the former can mask the latter completely. A. Papineau-Couture

**Lacquers for the canning industry.** T. Hedley Barry. *Food* 3, 51-3(1933).—A discussion of the qualities required. A. Papineau-Couture

**Sirups for canning.** H. C. S. de Whalley. *Food* 3,

57-9(1933).—Precautions which should be taken to avoid failures are explained. A. Papineau-Couture.

**Pressures produced in cans during sterilization.** W. B. Adam and J. Stanworth. Univ. Bristol Fruit & Vegetable Preservation Research Sta., Campden, *Ann. Rept.* 1931-32, 44-55.—App. is described for the detn. of temp.-pressure-vol. relationships. Because of the evolution of  $\text{CO}_2$ , re-soaked dried peas, if not properly blanched, may give dangerous pressures when retorted; blanching for 5 min. at boiling temp. reduced the  $\text{CO}_2$  evolution from 55 cc. to 20 cc./100 g. of peas. K. D. J.

**The chemistry of raspberry varieties with special reference to its bearing on canning quality.** Lucy D. M. Knight. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 32-46.—Sixteen varieties of raspberries grown under comparable conditions were analyzed for total N, titratable acidity, total sugars, reducing sugars, sucrose and sol. pectin. Large variations in chem. compn. were found in the varieties, but these did not provide any obvious basis for assessing canning qualities or of classifying the berries into dessert and culinary groups. Taste was not a reliable index of either acidity or of total sugars, and cloudiness in the sirup of canned fruits was not correlated with total acid content or the percentage of sol. pectin. Good canning qualities were closely related to high dessert properties and poor canning qualities were assocd. with culinary properties. K. D. Jacob

**Processing, cooling and storage of No. 10 cans of peas.** Wm. H. Harrison. *Canner* 76, No. 18, 7-8, 14(1933). The recommended safe and practical heat treatment for No. 10 cans of peas is 55-60 min. at a temp. of  $110^\circ$ . The retorts used for processing must be provided with air-pressure equipment so that the cans can be cooled under air pressure to avoid seam injury. C. R. Fellers

**Preliminary observations on flat sour spoilage in canned peas.** F. Hirst. Univ. Bristol Fruit & Vegetable Preservation Research Sta., Campden, *Ann. Rept.* 1931-32, 65-8. K. D. Jacob

**Factors influencing the hardness of dried peas.** G. Horner. Univ. Bristol Fruit & Vegetable Preservation Research Sta., Campden, *Ann. Rept.* 1931-32, 56-64. The hardness of canned dried peas depends upon the variety, the age and the method of canning. With other factors const., the hardness increases with the Ca and Mg contents of the water used for blanching the peas prior to canning; the amts. of Ca and Mg absorbed by the peas from water of a given degree of hardness approaches a max. in 5 min. By the addn. of 2% NaCl (free from Ca and Mg) to the blanching water the amt. of Ca absorbed is considerably reduced but is still directly proportional to the hardness of the water. The harder varieties of peas initially contain more Ca than the softer varieties. K. D. Jacob

**Isolation and identification of the organic nitrogenous and non-nitrogenous compounds occurring in the Alaska pea.** I. Presence of citric acid in the Alaska pea. S. L. Jodidi. *J. Im. Chem. Soc.* 55, 4863-4(1933).—By repeatedly extg. the evapd. ext. of Alaska pea with abs.  $\text{EtOH}$  and by treating the  $\text{EtOH}$  exts. in a definite way, citric acid was obtained (0.36% of the oven-dried pea). C. J. West

**Cranberry jelly.** R. F. Cox. *Food Ind.* 5, 318-9(1933).—The natural quick setting pectin of the cranberry is destroyed by the use of a com. pectinase prepn. and com. citrus pectin is added to replace it. Approx. 1 lb. of pectin is required for 100 lb. juice and 100 lb. of sugar. Whereas cranberry sauce forms a firm jelly at a sol. solids concn. of 12-13%, the cranberry jelly prepd. by this method contains a sol. solids content of about 65%, the same as other fruit jellies. C. R. Fellers

**Macaroni products.** J. A. LeClerc. *Cereal Chem.* 10, 383-419(1933). A comprehensive discussion is given of macaroni products, together with a description of methods of manuf. and tables showing compn. of macaroni products and other common foodstuffs. B. H. Bailey

**An investigation of quebrachitol as a sweetening agent for diabetes.** Robert A. McCance and Robert D.

Lawrence. *Biochem. J.* 27, 996-9(1933).—Quebrachitol is l-methylinositol. It is not nearly so sweet as cane sugar, and 2-3 times the amt. is necessary to obtain the same effect on the palate. In such amts. it produces cholic or diarrheic. Its use as a sweetening agent is not recommended. Benjamin Harrow

**Peanuts: their products and by-products.** Wm. F. Cross. *Rev. ind. agr. Tucumán* 22, 307-10(1932).—A review of the uses of peanuts for human and animal consumption, oil production and the plant as a green manure in crop rotation. Nelson McKaig, Jr.

**Barium as a normal constituent of Brazil nuts.** W. M. Seaber. *Analyst* 58, 575-80(1933). A sample of candy was examd. to see if anything was present that might cause sickness. In the analysis, a yellow ppt. was obtained with  $\text{ClO}_4$  and was proved to be caused by the presence of Ba. Further examn. showed that the Ba came from Brazil nuts used in the candy. Subsequently 17 other samples of Brazil nuts were examd. and all found to contain 0.06 (0.31% Ba. As a qual. test for Ba the reaction with rhodizonic acid was found most suitable. It seems that the Ba in Brazil nuts is present as an insol. salt of an org. acid but possibly some of this is dissolved by the  $\text{HCl}$  of the stomach and this may act as a mild poison on people particularly sensitive to  $\text{Ba}^{+2}$ . W. T. H.

**The kind of cacao beans the manufacturer wants.** A. W. Knapp, F. Wichi and Leon Olivier. *Food Ind.* 5, 408-9(1933). Cacao beans contg. moisture in excess of 8% will become moldy. If beans are dried at a temp. above  $50^\circ$  the flavor is largely destroyed. Fermented beans give the best flavor and no post-fermentation process has been as successful as fermentation at the point of origin. Unfermented beans are slaty in color and cheesy in texture. C. R. Fellers

**Report on (the analysis of) cacao products.** J. W. Sale. *J. Assoc. Official Agr. Chem.* 16, 559-60(1933); cf. *C. A.* 27, 147. A brief discussion of the rept. of the assoc. referees; cf. next 3 abstrs. A. P.-C.

**Report on (the determination of) milk proteins in milk chocolate.** Marie L. Offutt. *J. Assoc. Official Agr. Chem.* 16, 560-3(1933); cf. *C. A.* 27, 147. The following method is proposed: to 10 g. of finely grated chocolate in a suitable 8-oz. centrifuge bottle add  $2 \times 100$  cc.  $\text{EtOH}$ , centrifuge, decant the supernatant liquid, dry at about  $100^\circ$ , powder the residue in the bottle with a flattened glass rod, add 200 cc. of 3% Na oxalate, let stand 4 hrs. with frequent shaking, centrifuge, filter, det. N in a 50-cc. aliquot; dil. a 100-cc. aliquot to slightly less than 200 cc., ppt. proteins by addn. of 2 cc. glacial  $\text{AcOH}$ , make to 200 cc., filter, and det. N in a 100-cc. aliquot. The difference between the 2 N figures gives the casein N, and casein multiplied by 1.25 gives total milk proteins. Collaborative comparison of this method with the present A. O. A. C. method indicated more uniform agreement by the former than by the latter. A. P.-C.

**Report on (the determination of foreign fat in) cacao butter.** W. O. Winkler. *J. Assoc. Official Agr. Chem.* 16, 563-4(1933); cf. *C. A.* 27, 147. Collaborative study of the "A" and "B" nos. showed that the procedures have merit, but that the techniques should be specified in greater detail. A. P.-C.

**Report on (the determination of) sucrose and lactose in milk chocolate.** J. Fitchelson. *J. Assoc. Official Agr. Chem.* 16, 561-6(1933); cf. *C. A.* 27, 148. The previously described methods were studied collaboratively on 2 samples of authentic milk chocolate. Results for sucrose by the proposed method were quite satisfactory. The proposed method for lactose gives results that are more concordant and closer to theory than the polarimetric method. Minor changes are suggested in the technic of the proposed methods for sucrose and lactose, which are described in detail. A. Papineau-Couture

**Technological study of Ivory Coast coffees.** F. Heim de Balsac, A. Parvraud and L. Lefèvre. *Bull. agence Gén. colonies* 26, 1236-42(1933); cf. *C. A.* 25, 4947.—Analyses of 5 samples showed a caffeine content of 0.74-

1.16%. The com. value of the samples is discussed.

A. Papineau-Couture

**Report on (the determination of caffeine in) coffee.** E. M. Bailey and W. J. Mathis. *J. Assoc. Official Agr. Chem.* 16, 567-8(1933); cf. Clifford, C. A. 26, 783.—Preliminary expts. indicated that, with proper precautions, detn. of N by the usual method in the caffeine residue obtained from decaffeinated coffee was sufficiently accurate for all practical purposes, and the use of micro-analysis is not essential.

A. Papineau-Couture

**Determination of chlorogenic acid in raw coffee.** H. Jurany. *Z. anal. Chem.* 94, 225-32(1933).—Take 7-8 g. of very finely ground raw coffee, or 15-20 g. of roasted coffee, and mix the sample with fine quartz sand. Ext. for 4 hrs. under reflux condensation with 70 cc. of 80% alc. (with roasted coffee, further grinding is unnecessary). Remove the raw coffee from the extn. thimble, dry at 50-70° and grind the sand-coffee mixt. in an agate mortar as finely as possible. Mix with an equal quantity of coarse sea-sand and again ext. with fresh alc. until a fresh portion of the ext. gives no ppt. with  $Pb(OAc)_2$  soln. The total time of extn. should be 6-8 hrs. To the combined exts. add 2 g. of solid paraffin, to bind the fat and wax, and evap. to 50 cc. to remove alc. Cool, break up the paraffin, and transfer with water to a 150 cc. measuring flask, filtering through a pleated filter. Of the filtrate, which need not be perfectly clear, transfer a large aliquot to a 400 cc. beaker, add 20 cc. of alc. and enough water to make 200 cc. Heat to about 90° and slowly add 12-15 cc. of 25%  $Pb(OAc)_2$  soln. to ppt. the chlorogenic acid. Heat 10 min. over a small flame and cool in ice water for 1 hr. Filter off the lemon-yellow ppt. and wash it with a little cold water. Transfer the ppt. to a Philipp's beaker with a little hot water. At a vol. of not over 100 cc., sat. the water with  $H_2S$ . This serves to ppt. the  $Pb^{++}$  and leave the free chlorogenic acid in aq. soln. Filter and remove  $H_2S$  by the passage of a stream of air. Det. the content of chlorogenic acid by measuring the optical rotation in a polariscope and also by titrating with 0.1 N NaOH to an end point with bromothymol. The 2 detns. should agree. Samples of raw coffee analyzed by this method showed 8-9% of chlorogenic acid.

W. T. H.

**Report on (the analysis of) flavors and non-alcoholic beverages.** John B. Wilson. *J. Assoc. Official Agr. Chem.* 16, 541-3(1933), cf. C. A. 27, 147. The methods of the Bur. of Industrial Alc. were studied collaboratively on exts. of almond, anise, lemon, nutmeg, orange, peppermint, rose, rosemary, spearmint, thyme, wintergreen and imitation wintergreen, on the one hand, and cinnamon and clove on the other. The results were somewhat erratic, but this can be corrected by using standardized Halcock bottles and measuring the solvent by means of a long 10-cc. buret. Adoption of the method as official by the A. O. A. C. is recommended.

A. P.-C.

**An alcoholic standard for cider.** D. W. Stewart. *Analyst* 58, 602-3(1933).—Cider sold in England contains 2-11% EtOH by vol. and any attempt to establish a legal standard is likely to be embarrassing to some honest growers of apples.

W. T. H.

**Cider-making trials for the season 1931-32.** V. L. S. Charley and P. T. H. Pickford. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 139-55; cf. C. A. 27, 4319.—Data are given on the compn. and characteristics of juices and ciders prepd. from numerous varieties of apples.

K. D. Jacob

**New filtering method produces clearer, more salable cider.** Roy E. Marshall. *Canner* 76, No. 16, 7-8, 24 (1933); cf. C. A. 27, 4319.

C. R. Fellers

**Volatile acidity in cider.** Vernon L. S. Charley. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 156-4. **Estn. and identification of volatile acids in cider.**—Methods for detg. volatile acids are outlined and comparative data on synthetic and natural ciders are given; the tentative English method gave higher recoveries than either the French official method (Duclaux) or the Swiss micro method (Widmer). Examn. of cider prepd. from the Kingston Black variety of apple showed that AcOH

is the predominating volatile acid; small amts. of caprylic, caproic and formic acids were present, but valeric acid was absent. **Development of volatile acidity in bottled and cask ciders.**—At lab. temps. development of volatile acidity is lower in bottles closed with screw stoppers than in those closed with crown corks; champagne bottles are advisable for long storage periods. Development of acidity is markedly retarded by storage at cellar temps., and to a less extent by placing the bottles on their sides. Prevention of ullage is of primary importance in retarding the increase in acidity in cask ciders; treatment of the casks with acid-resisting enamels also has a retarding effect, greatly reduces evapn. and imparts no undesirable characteristics to the cider.

K. D. Jacob

**Beam's color test for hashish.** A. Lucas. *Analyst* 58, 602(1933).—Polemical with respect to a pamphlet published by Henri Trolle (cf. C. A. 27, 4192).

W. T. H.

**Report on analysis and interpretation of mayonnaise.** Henry A. Lepper and Frank A. Vorhes, Jr. *J. Assoc. Official Agr. Chem.* 16, 545-56(1933).—The compn. of mayonnaise can be obtained from the detn. of total solids, total fat (by acid hydrolysis), total acidity, total N and total  $P_2O_5$ , and the following formulas, in which P is percentage of total  $P_2O_5$  and N percentage of total N: percentage of yolk =  $75.69 P - 1.802 N$ ; percentage of white =  $60.80 N - 114.59 P$ ; percentage of total egg = percentage of yolk + percentage of white; percentage of white in egg component =  $100(\text{percentage of white}) / \text{percentage of total egg}$ ; vegetable oil = total fat - (yolk  $\times 0.3188$ ); vinegar (4% acid strength) = total acidity as AcOH  $\times 25$ ; minor constituents (sugar, salt, spices, stabilizers) = total solids - (yolk  $\times 0.5047$ ) - (white  $\times 0.1221$ ) - vegetable oil; added water =  $100\% - \text{total egg} - \text{vegetable oil} - \text{vinegar} - \text{minor constituents}$ .

The methods are those of the A. O. A. C. with the following modifications: the tentative method for total acidity in salad dressings was altered to allow the use of a larger sample; the total N method was modified to permit the use of a larger sample and to remove oil before digestion; the total  $P_2O_5$  method was modified by specifying the burning of the sample in Pt instead of charring in glass so that the oil might be burned off before placing in the muffle. The methods were studied collaboratively on 6 samples prepd. in the lab. to represent normal types of mayonnaise and also several deviations from the present U. S. standard. From a discussion of the results, it is concluded that the methods are satisfactory.

A. Papineau-Couture

**Report on (the analysis of) gelatin.** R. M. McChurin. *J. Assoc. Official Agr. Chem.* 16, 547(1933); cf. C. A. 27, 147, 5117. A brief discussion of the prepn. of gelatin samples for the detn. of Cu.

A. Papineau-Couture

**Report on (the determination of) volatile oil in spices.** J. F. Clevenger. *J. Assoc. Official Agr. Chem.* 16, 557-9 (1933). A collaborative study of the Clevenger method (C. A. 22, 2439) on unground and ground sage and on ground nutmeg and pimento showed reasonable agreement in yield of volatile oil in most instances; the lower yields indicate lack of uniformity in mixing the sample, incomplete distn., or the loss of some volatile oil in the steam during distn. The precautions which should be taken in carrying out the detn. are pointed out. The  $d_4^{20}$ ,  $n_D^{20}$ , acid no. and ester no. of the oils obtained were detd., and the causes of the variations in results are briefly discussed.

A. Papineau-Couture

**Identification of flavoring constituents of commercial flavors.** IV. Identification of benzoic acid. John B. Wilson and Geo. L. Keenan. *J. Assoc. Official Agr. Chem.* 16, 581-2(1933); cf. C. A. 27, 5439. To fraction B obtained by carrying out the procedure for the qual. sepn. of classes (C. A. 27, 147) or other extd. matter suspected to contain benzoic acid add a slight excess of 40% aq. hydrazine hydrate soln., mix, let stand 15-20 min. at room temp., evap. on the steam bath till dry or till the odor of  $NH_3$  is no longer perceptible; in presence of benzoic acid, benzhydrazide is formed, m. 112°, and has the following  $n_D$ :  $n_D^{20}$  1.545 (common),  $n_D^{20}$  1.567 (most

common of the indices and closely approximating the  $\gamma$ -value),  $\gamma$  1.685 all  $\approx 0.003$ . To obtain larger crystals lending themselves to microscopical examn. according to the optical-immersion method, dissolve the residue in warm  $\text{H}_2\text{O}$ , filter and allow to evaporate spontaneously. Cinnamic, anisic, stearic, palmitic and myristic acids, also vanillin, coumarin and heliotropine, which might be found in fraction B under practical application of the sepn., do not give any crystals when subjected to the test.

**Economical clarification through use of enzymes.** J. J. Willaman. *Food Ind.* 5, 294-5, 301 (1933); cf. C. A. 25, 3738. Pectinase enzyme from fungi has the property of changing fruit pectins to a water-sol. form consisting largely of galacturonic acid and galactose. The addn. of 1 lb. of Pectinol, a com. pectinase prepn., to 100 gal. of fruit juice at 15-6° normally causes pptn. of colloidal matter and destruction of pectin so that the juice is easily filtered. The enzyme becomes less active and effective at temps. above 49°. Fruit juices are variable in their colloid and pectin characteristics and special enzyme prepn.s have been developed for several different juices. The enzyme action makes filtration through an ordinary filter press, aided by a siliceous filter aid, very rapid and effective. The clear juices may be subsequently filtered through a Seitz or other germ-free filter and bottled without pasteurization. Maintenance of sterility in juice containers without the use of heat is difficult under industrial conditions. The use of pectinase has no effect on flavor and greatly enhances the appearance of the juices.

**Dehydrated kelp.** M. J. Walsh. *Food Ind.* 5, 229 (1933). Dehydrated kelp is pressed into tablets and sold as a nutritional supplement. The structure and color of the original substance are retained. C. R. F.

**Bone extracts for use as food.** D. I. Lobanov and Z. V. Kochetkova. *Izvestiya Tsentral. Nauch. Issledovatel. Inst. Pischevoi Prom. Separate 1930*, 18 pp. Fresh bones yield about 15%, and boiled bones 7-8%, of fat which is edible without any further refining. Old, dry bones yield some fat, but it is not edible. The best soup stock is obtained by an acid hydrolysis, the autoclave pressure being held at 1.5 atm. for 3-4 hrs. J. F. S.

**Edible yeast.** R. V. Givartovskii. *Izvestiya Tsentral. Nauch.-Issledovatel. Inst. Pischevoi Prom. Separate 1930*, 24 pp.—The properties of *Torula utilis* are described, in comparison with other strains of *Torula*. A detailed procedure is given for com. production of edible yeast from pure cultures of *Torula utilis* in a molasses mash, and a cost sheet is presented. Julian F. Smith.

**Edible yeasts and their uses.** R. V. Givartovskii. *Izvestiya Tsentral. Nauch.-Issledovatel. Inst. Pischevoi Prom. Separate 1930*, 22 pp.—European and American products which exploit the medicinal properties of yeast are discussed. Based on a series of expts. it is suggested that edible yeasts should be produced in Russia and used in making medicinal yeast, vitamin bread, crackers, cakes, candies, yeast broth and yeasts with high N content.

**Estimation of crude fiber and soluble carbohydrate in certain foods and fodders.** Hermann Schmidt-Hebbel. *Pharm. Zentralhalle* 74, 600 (1933).—A crit. study of methods ordinarily employed in such cases forces the conclusion that the procedure of König is basically sound and with certain modifications can be advantageously employed for the estn. of crude fiber and sol. carbohydrates (total carbohydrates resulting from treatment with  $\text{HCl}$ ). The modified method eliminates the use of glycerol and employs the aq. filtrate (exclusive of alc. and  $\text{Et}_2\text{O}$  washings) in detg. the sol. carbohydrates. The various operations are given in detail. W. O. E.

**The surpassing importance of the  $p_{\text{H}}$  number in the investigation of silo fodder.** Karl Kneist. *Weidewirtschaft u. Futterbau* 8, 1-3 (1933). Suppl. to *Deut. Landw. Tierzucht* 37, No. 1 (1933). The importance to the farmer of obtaining  $p_{\text{H}}$  analyses of his silo fodder is urged. Silo fodder with a  $p_{\text{H}}$  below 4.2 is considered very good; when the  $p_{\text{H}}$  is above 4.9 it is considered poor. B. C. B.

**The mineral content of feeds.** Frank E. Corrie. *Fertiliser, Feeding Stuffs, Farm Supplies J.* 18, 341, 344, 346 (1933).—Data are given on the protein, ash,  $\text{CaO}$ ,  $\text{P}_2\text{O}_5$ , and Cl contents of numerous feeding stuffs.

K. D. Jacob

**Rye germ cake as a component of stock feeds.** M. I. Dyakov, A. I. Vereninov, Yu. V. Golubentzeva and O. A. Fedorova. *Schriften zentral. biochem. Forschungsinst. Nahr.-Genussmittelind.* (U. S. S. R.) 1, 291-300 (1932).—

Rye germ cake is highly nutritious for cattle, horses and hogs. The oil should be removed as thoroughly as possible, the cake should be free from grit and dirt and the moisture content should not exceed 10-12%. The ash is high in P and low in Ca; addn. of Ca salts may therefore be desirable in mixed feeds. The value of the cake is enhanced by the presence of vitamins A, B and E, and by its high content of easily digested protein. J. F. S.

**Report of the physiological chemist.** A. Viswanatha Iyer. *Imp. Inst. Agr. Research Pusa, Sci. Repts.* 1931-32, 113-21 (1933); cf. C. A. 26, 5356. *Indian coarse fodders*.—Data are given on the org. matter, protein, fiber and carbohydrate contents of Bolarum, Tornagallu, Aurangabad, Boda and scented grass hays, also Meerut and Jubbulpore hays cut at various stages of growth. The Aurangabad hay caused purging of bullocks and rendered the urine exceptionally highly acid. *Acid-base balance*.—Expts. with Bolarum hay, which produced acid urine, and ragi straw rations for cattle showed that Ca is markedly deflected into the urine from the feces when there is a tendency toward acidity in the urine.

K. D. Jacob

**Feeding experiment with tapioca meal on milk cows.**

E. Brouwer. *Verlag. landb. Ondersok. Rijkslandbouwproufs* No. 38C, 145-177 (1932).—Tapioca meal with the addn. of protein in some form is a satisfactory feed for milk cows. R. M. Barnette

**The composition and feeding value of pig swill.** Brynmor Thomas. *Fertiliser, Feeding Stuffs, Farm Supplies J.* 18, 359 (1933).—Over a period of 6 months, the fat content of garbage from hotels (I), restaurants (II), 1st-class cafes (III) and 2nd-class cafes (IV) averaged 22.9, 19.7, 17.3 and 20.9%, resp. The protein content averaged 25.1, 12.8 and 15.3% in garbage from I, III and IV, resp. Garbage from I averaged 8.8% ash which was highly phosphatic.

K. D. Jacob

Spartan barley (Rather) 16. Rept. of the imperial agricultural chemist [on potato storage] (Mukerji) 15. Printing on sausage casings (U. S. pat. 1,929,394) 26.

**Apparatus for evaporating milk, etc.** Hans Luber. *Ger.* 580,108, Oct. 10, 1933.

**Milk powder.** Anthony R. Sanna. U. S. 1,929,450, Oct. 10. Milk is treated (as by the method described in U. S. pat. No. 1,414,214; C. A. 16, 2185) to bring the caseins and other albuminoids into "a state of adherence." Coagulation of the albuminoids and casein is effected by adding an acid and the coagulants are sepd.; the mass is rendered alk. to a degree to convert it from an insol. to a sol. state, and is desiccated.

**Emulsifying apparatus suitable for use with milk and butter, etc.** Harold G. MacChesney. U. S. 1,530,686, Oct. 17. Mech. and structural details.

**Vegetable oil shortenings for foods.** Herbert Humphreys. U. S. 1,929,588, Oct. 10. Oleaginous materials such as vegetable oil shortenings are prepd. for packaging by chilling to a congealing temp., intermixing with air, raising the temp. of the mass by incorporation of a suitable proportion of similar heated material and then further heating the mixt. to the desired packaging temp. (a certain proportion of the finally heated product being packaged and another portion used in the intermediate heating operation).

**Lard.** Halvor O. Halvorson, Robert C. Murray and Edward M. Schnitz (to Geo. A. Hormel & Co.). U. S.

- 1,930,091, Oct. 10. Fat-contg. tissue is treated to render it electrically conductive (as by maceration and heating) and a sufficient elec. current is passed through it to generate heat for rendering out contained fat without scorching the N-contg. substances present. The rendered fat is sepd. from the solids and then heated to a temp. above the b. p. of water. App. is described.
- Apparatus for treating oranges or other fruits with mold-inhibiting solutions. Ernest M. Brogden (to Brogden Co.). U. S. 1,931,463, Oct. 17. Various mech. and operative details are described.
- Drying fruits and vegetables. Alfred H. McComb (one-half to Everette R. Peacock). U. S. 1,929,437, Oct. 10. In the rapid drying of vegetables, fruits, etc., substantially one-half of the moisture content of the material is first extd. by use of a warm dry gaseous fluid such as air and the partially dried material is then placed in a vacuum and indirectly heated to effect further removal of moisture, followed by cooling in the vacuum to a temp. sufficiently low that air may be allowed to come into contact with it without causing undesired oxidation. App. is described.
- Evaporators for concentrating fruit juices. Mihran K. Serailian. Brit. 394,587, Jan. 29, 1933. Addn. to 303,956 (C. A. 23, 4513).
- Removing tannin from apple juice. Frederick A. Karmann (to Industrial Research Laboratories Ltd.). U. S. 1,929,642, Oct. 10. For removing tannin while substantially retaining malic acid, an insol. compd. of Fe is formed in the juice (suitably by adding Fe and air and heating) and is sepd.
- Flavored gelatin products for preparing gelatin desserts. Clarence C. Zeigler (to Swift & Co.). U. S. 1,929,732, Oct. 10. See Brit. 372,780 (C. A. 27, 3015).
- Tea and coffee beverages. Willy Stelkens (to Albert T. Otto & Sons). U. S. 1,930,257, Oct. 10. A dry compn. for prepg. beverages comprises tea or coffee and finely subdivided activated carbon contg. adsorbed glycerol, which serves to remove a portion of the caffeine and bitter substances.

### 13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

- Ancient Egyptian materials and industries about 1350 B.C. A. Lucas. *Analyst* 58, 654 (1933). The materials and industries described are stone and stone-working, faience and its manuf., glass and glass making, woven fabrics and weaving, wood and wood working, pigments and varnish, metals and metal working.
- W. T. H.
- A century of development in industry and engineering A. P. M. Fleming. *Elec. Eng.* 52, 666 71 (1933). Historical.
- W. H. Boynton
- Science as affecting industry. Gustav Egloff. *Cereal Chem.* 10, 457 (1933).—Several examples are given showing how science has enabled many industries to make great strides, e. g., rubber, steel, oil, etc.
- L. H. B.
- Operation and function of chemical laboratories in the French navy. Saint-Serun. *Chimie et Industrie Special* No. 1, 1253-4 (June, 1933).
- A. Papineau-Couture
- Problems of technical reactions. I. Catalytic hydration. Otto Schmidt. *Z. Elektrochem.* 39, 824 37 (1933). A review.
- G. G.
- Supplementing natural resources. H. R. Howe. *Elec. Eng.* 52, 188 9 (1933). An address. Science has produced not mere substitutes but actual equivalents and sometimes items that are superior to those customarily provided by nature.
- C. G. F.
- Performance of agitators in liquid solid chemical systems. A. W. Hinson and G. A. Wilkins. *Ind. Eng. Chem.* 25, 1196 1203 (1933).—The factors involved in the agitation of solid liquid systems have been studied by following the soln. of BzOH in water and various oils in geometrically similar systems of different sizes. In free rotational agitation the intensity of agitation increases with speed of stirrer and size of equipment and decreases as the liquid viscosity increases. Agitation impeded by the addn. of baffles reduces the intensity of agitation. A general relation for each type of agitation is expressed in terms of composite variables. The power consumption of various systems and the effect of agitator design have been investigated.
- L. W. T. Cummings
- Grinding in ball mills. G. Helm. *Ber. deut. keram. Ges.* 13, 198-213 (1932).—The effects of the no. of revolutions per min. in the wet grinding, of the amt. of charge, size of grinding pebbles, amt. of grinding pebbles, and different types of grinding pebbles were studied.
- H. G. Schurecht
- The sedimentation of fine particles in liquids. A survey of theory and practice. R. F. Stewart and R. J. Roberts. *Trans. Inst. Chem. Engrs.*, Advance proof 1933, 14 pp.—A summary is given of the theory and actual behavior of fine particles subjected to sedimentation, together with a discussion of the industrial equipment used.
- L. W. T. Cummings
- Evaporation and its applications in the concentration of industrial liquids. E. Lafitte. *Mém. compt. rend. soc. ing. civils France* 85, 1258 90 (1932).—A discussion of some aspects of the problem of evapn. and its applications to the treatment of natural waters and in the sugar and distillery industries.
- A. Papineau-Couture
- Measurement of tube-wall temperatures in heat-transfer experiments. G. M. Hebbard and W. L. Badger. *Ind. Eng. Chem., Anal. Ed.* 5, 359 62 (1933).—A chord hole is drilled in the metal of the tube wall, and from the ends of this hole a groove is cut around the rest of the circumference of the tube. The couple junction is threaded into the chord hole, soldered in place, and the leads are secured in the grooves with Bakelite and kaolin. Advantages claimed are (1) there is an undisturbed fluid film over the part of the tube where the junction is located; (2) perfect metallic contact between junction and tube; (3) the leads are withdrawn through an isothermal section; (4) the installation is reasonably robust; (5) the readings are apparently accurate and reproducible.
- W. L. Badger
- Heat transfer in an industrial glass heat exchanger. H. C. Bates. *Chem. and Met. Eng.* 40, 512 13 (1933).—Overall heat transfer coeffs. from condensing steam to water were detd. on an exchanger, the inner tube of which was a 1 in. Pyrex glass tube. The water velocity was varied from 0.5 to 3 feet per sec., and the steam pressure from 18 to 100 lb. No mixing chambers were used.
- L. W. T. Cummings
- Influence of surface roughness on heat transmission to water. W. Pohl. *Forsch. Gebiete Ingenieurw.* A or B4, 230 8 (1933).—Wall roughness was detd. by pressure drop measurements. The coeff. of resistance can be expressed by the equations  $\zeta = c(1/Re)^n$ ;  $x$  and  $c$  increase with increasing roughness. Measurement of heat transfer with changing roughness shows that the coeff. is a power function of the velocity. The equation developed is  $\alpha = kw^n$ , where  $n = 3.6$  and  $k = 550 n - 1200$ .
- M. C. Rogers
- "Nitrogen narcosis" (oxygen deficiency) and an experimental method of representing it. Fr. Ruhe. *Draeger-Hefte*, Sept./Oct. 1933, 2383 7. A device for demonstrating the effect of O deficiency is described and the results of some expts. are given.
- A. I. K.
- Professional benzene poisoning. A. Fell. *Presse méd.* 41, 129-30 (1933); cf. C. A. 27, 4323.
- A. E. M.
- Accident prevention in the chemical industry. C. Rheinfels. *Chem. Fabrik* 1933, 450 2.—A summary of a report covering 1932; cf. C. A. 27, 1419.
- J. H. Moore
- Development of the constructive features of the modern gas mask. Heinrichs. *Z. ges. Schiess.-Sprengstoffw.* 28,

- 329-33(1933).—Different types of German gas masks are described and shown by photographs. A. L. K.
- Thermal insulation.** Ezer Griffiths. *Trans. Inst. Chem. Engrs.* 10, 35-44(1932).—A detailed discussion is given of methods of heat-cond. measurement used at the Natl. Phys. Lab. (Great Britain). The testing of various types of insulating materials is discussed, e. g., slab cork, granulated cork, cork wool, slag wool, Al foil, compressed peat, pumice concrete and diatomaceous earth products. Exptl. results upon the heat radiated from the external surface of a hot pipe in air are given. L. B. Miller
- Several mechanical and thermal properties of electric insulator substances. Ulrich Ritzow. *Z. tech. Physik* 14, 424 8(1933).—Data on sp. gr., mech. strength, linear expansion, sp. heat and heat cond. are given for natural materials, basalt, marble, serpentine, mica, shales, asbestos, and for the ceramic insulators, glasses, Mycalex, quartz, porcelain, sillimanite, steatite and stoneware. Arthur Fleischer
- Measurement of colors and its industrial applications (Toussaint) 2. Preserving rubber [insulating] compns. (Brit. pat. 391,510) 30. Aliphatic fluoro halides (U. S. pat. 1,930,129) 10.
- Bader, W.:** Die Technik der chemischen Operationen. Basel: B. Wepf & Cie. 430 pp. M 14 50, bound, M. 16.
- Bain, H. Foster:** Ores and Industry in the Far East. The Influence of Key Mineral Resources on the Development of Oriental Civilization, with a chapter on Petroleum by W. B. Heroy. Revised ed. New York: Council on Foreign Relations, Inc. 288 pp. \$3 00. Reviewed in *Eng. Mining J.* 134, 301(1933).
- Dugans, Thos. H.:** Solvents. 3rd ed., enlarged. New York: D. Van Nostrand Co., Inc. 197 pp. \$5 00.
- Humery, René:** La lutte contre les fumées, poussières et gaz toxiques. Paris: Dunod. 351 pp.
- Effecting endothermic catalytic reactions.** Alphons O. Jaeger (to Selden Co.). U. S. 1,930,053, Oct. 10. The reaction components, at temps. above those necessary for the reaction, are passed in vapor form through heat-exchange elements at least partly embedded in a layer of contact mass in indirect heat-exchange relation with the mass; the flow of vapors is then reversed and they are caused to flow in direct heat-exchange relation with the catalyst and with the incoming vapors, the vapor flow is again reversed and the vapors are passed through the catalyst at temps. of about 200-400°. App. is described, and catalysts may be used such as dehydrating, dehydrogenating and decarboxylating agents, etc.
- Clarifying liquids.** Marsden C. Smith. Fr. 750,615, Aug. 14, 1933. In clarifying liquids by flocculation, the flakes which have been recently formed are carried in suspension in a circulating current, following a horizontal direction, and maintained in intimate contact with previously formed flakes. The latter may be caused to pass in countercurrent to the former.
- Purifying aqueous liquids.** Carbo-Norit-Union Verwaltungs-Ges. m. b. H. Ger. 579,643, June 29, 1933. Addn. to 534,204 (C. A. 26, 788). Aq. liquids which have been preliminarily purified by extn. with a solvent are further purified by treatment with a solid adsorbent, from which the adsorbed substances are afterward recovered by direct treatment with a gas or vapor such as steam. The treatment of waste waters contg. phenols is mentioned.
- Compressing and cooling gases such as in liquefaction.** Niels C. Christensen. U. S. 1,929,350, Oct. 3. Various details of app. and operation are described.
- Apparatus for separating oxygen and nitrogen from air by liquefaction and fractional distillation.** Niels C. Christensen. U. S. 1,929,349, Oct. 3. Various structural and operative details are described.
- Apparatus for transferring liquid air, etc.** Harold B. Thompson (to Linde Air Products Co.). U. S. 1,930,731, Oct. 17. Various structural and operative details are described.
- Aqueous dispersions such as those of oils, fat, and fatty acids.** Heinrich Ulrich and Curt Schuster (to I. G. Farbenind. A.-G.). U. S. 1,930,845, Oct. 17. Aq. dispersions of fatty substances such as olein, olive oil or mineral oil are formed contg. a small proportion of a salt of an aliphatic amine contg. at least one alkylol group with an aliphatic carboxylic acid such as nonyllic, caprylic, undecylic, lauric or claidic acids, e. g., octadecylethanolamine.
- Colloidal dispersions such as aqueous wax dispersions.** Leo Kollek and Franz Pohl (to I. G. Farbenind. A.-G.). U. S. 1,930,853, Oct. 17. A viscid polymerization product of an alkylene oxide contg. 2 or 3°C atoms is used as a dispersing agent in forming dispersions such as those of montan wax, gum mastic, pyroxylin lacquers, wall-paper pigments, etc. Numerous examples are given.
- Separating oil-water emulsions.** Fritz E. Fuchs (to Dehydro Co.). U. S. 1,929,390, Oct. 3. A material for use in sepg. water-in-oil emulsions such as may be discharged from wells consists of a blown-oil soap formed with a caustic and to which diethylene glycol is added.
- Leaching system suitable for removing parchementizing or vulcanizing agents from materials such as those containing zinc chloride.** Alfred W. Laird (to Western Elec. Co.). U. S. 1,929,927, Oct. 10. Various details of app. and operation are described.
- Heating fluids such as steam by use of a plurality of waste heat exchangers.** Virgil A. Rumble (to Bailey Meter Co.). U. S. 1,930,456, Oct. 10. The fluid is proportioned through the exchangers in accord with a comparison of the temps. of the fluid leaving the exchangers. App. is described.
- Process and apparatus for coating surfaces with fibrous material and a binder.** J. W. Roberts Ltd. and Norman L. Dolbey. Ger. 584,037, Sept. 13, 1933. See Brit. 368,368 (C. A. 27, 2228).
- Fireproofing materials.** Élie L. Raymond. Fr. 750,605, Aug. 14, 1933. Materials such as rubber are fireproofed by the addn. of (1) substances which retard decompn. and inflammation at high temps., e. g., carbohydrates, C<sub>14</sub>H<sub>10</sub>, phenanthrene, polyhalohydrocarbons, polyhaloacids (tetrabromophthalic acid), mineral acids or salts such as citrates, tartrates, arsenites and arsenates, particularly of NH<sub>4</sub> and (2) substances which raise the flash pt. and reduce the combustibility of gases given off by heat decompn., e. g., volatile substances giving neg. gaseous ions at a high temp., which prevent the production and propagation of flame, such as bromides of NH<sub>4</sub> or Hg, arsenites or arsenates of NH<sub>4</sub>, Hg, Al, Sn and volatile acids.
- Impregnating porous materials such as cellulose pulp with asphalt, etc.** Philip P. Gray and Ernest K. Werle (to Fibre Conduit Co.). U. S. 1,930,646, Oct. 17. A porous body such as a fiber conduit is immersed in impregnating material such as melted pitch in three successive stages, the second of which is at a lower temp. than the first and third stage.
- Heat-insulated portable chamber for storing solid carbon dioxide, etc., provided with means permitting removal of the refrigerant from any part thereof without exposing the remainder to the outside air.** Rudolf Kurth. Brit. 394,592, June 29, 1933.
- Insulation suitable for use on submarine cables.** Archie R. Kemp and John H. Ingmanson (to Bell Telephone Laboratories, Inc.). U. S. 1,930,274, Oct. 10. A mixt. contg. at least 80% of gutta-percha, balata and rubber (at least half of this portion being rubber) is incorporated with a small proportion of an anti-oxidant such as diphenylethylenediamine. Cf. C. A. 27, 4800.
- Electric insulation.** Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 395,507, July 20, 1933. Laminated material, suitable for elec. insulation, consists of layers of fibrous material, e. g., paper, fabric, treated with a soln. of an amine-aldehyde resin and united by pressure at a temp.

high enough to convert the resin to the infusible and insol. condition but not to infuse the fibrous material. The resins of Brit. 348,030 (C. A. 27, 4701) may be used and  $\text{SnCl}_4$ , e. g., may be added to accelerate hardening. Cf. C. A. 27, 2743.

Paper for electrical insulation. Standard Telephone & Cables Ltd., Thomas R. Scott and Malcolm C. Field. Brit. 395,737, July 24, 1933. Paper for condensers, power transformers, insulation of power cables or joints

for power cables, etc., is obtained by treating the dry fiber or paper by a controlled process of partial acetylation such that the product is substantially free from triacetate; paper so treated retains its mech. strength and is less absorbent to moisture. Being porous, the paper may be impregnated.

Insulating oils for electrical apparatus. Seymour W. Ferris (to The Atlantic Refining Co.). Brit. 394,404, June 29, 1933. See Fr. 729,425 (C. A. 26, 6119).

## 14 -WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Berlin municipal water works, 1928-1933. A. Swyer. *Gas u. Wasserfach* 76, 717 20(1933).—A description of improvements in the several pumping stations, principally in pumping equipment.

Interesting phases of Chicago's water works activities. Myron B. Reynolds. *J. Am. Water Works Assoc.* 25, 1321-38(1933).—Many problems have developed because of the great area covered. Those of a mech. nature cover pumping, pressure, and damage from building. Those of a chem. nature involve  $\text{CaCO}_3$  deposits, Cl absorption and flocculation.

New Saxon laws for the construction, protection and supervision of potable water-supply systems. Aug. F. Meyer. *Gas u. Wasserfach* 76, 701 4(1933). R. W. R.

Ammonia salts in water treatment. A. J. Smalshaf. *J. Southeastern Sect. Am. Water Works Assoc.* 3, No. 1, 31 43(1933).

Adsorption of copper sulfate by aluminum floc. C. J. Brockman. *J. Southeastern Sect. Am. Water Works Assoc.* 3, No. 1, 28-30(1933). Data indicate that the addn. of 8.85 p. p. m. of alum to a neutral water contg. as high as 1.0 p. p. m.  $\text{CuSO}_4$  removes practically all the  $\text{CuSO}_4$ .

The bacteriology of water. E. S. Stokes. *Chem. Eng. Mining Rev.* 25, 61 3(1933). A review resulting in the following conclusions: (1) There are no distinctive water bacteria. The bacteria present in water are, in the absence of specific contamination, derived from contact of the water with the air or earth. (2) The no. and species of bacteria found in water by the ordinary tests only show those that will grow under the condition imposed by the test. (3) The *Es. coli* is a group of organisms widely distributed in nature. There is no specific test to show whether or not any individual, giving typical reaction of this group, has actually been derived from a human source. (4) A water cannot be condemned merely on account of the presence of *Es. coli*, but their no. may be such as to excite suspicion and create a demand for investigation. (5) Bacteriol. examn. is essential for checking the efficiency of a treatment plant.

Rapid bacteriological investigation of water samples. Schmidt-Lange. *Gesundh.-Ing.* 56, 486 7(1933).—Plating the samples on agar and then counting the colonies in 6-8 hrs. with the aid of a microscope is recommended.

Removal of bacterial flora from water in the settling basin by added clay dispersions. Edward M. Slocum. *J. Southeastern Sect. Am. Water Works Assoc.* 3, No. 1, 14-52(1933).—Bleaching clay of high adsorptive ability aids the  $\text{Al}(\text{OH})_3$  in building up a heavy floc, thus increasing the settling rate, removing the org. colloids more thoroughly, and decreasing the turbidity. Because of the adsorptive power of the clay for  $\text{Cl}_2$  the sediment is also rendered sterile.

Water softening. E. L. Filby. *3rd Ann. Arkansas Water Works Conf.* 1933, 9-13. —A report on the 1st year's operation of the new lime-soda softening plant at Niles, Kans., from the economic standpoint.

Water softening and iron removal. E. W. Bacharach. *3rd Ann. Arkansas Water Works Conf.* 1933, 13 14. —A brief description of the plant at Clarksville, Ark. Raw

water is pumped from wells through an aerator, flows by gravity to the mixing chamber, then to the settling basin, the carbonating basin, and the filters. M. G. Moore

Errors in determination of carbonate in boiler waters. W. C. Schroeder. *Ind. Eng. Chem., Anal. Ed.* 5, 389 93(1933); cf. C. A. 26, 4601. —The errors involved in the use of the Winkler method and the phenolphthalein-methyl orange method for this purpose are discussed. S recommends that any method used be checked against the evolution method.

Commercial aspects of high boiler pressures. A. G. Christie. *Power Plant Eng.* 37, 469 70(1933). —Increased efficiency and lower plant investment are in favor of high-pressure boilers. Feed water requirements while more stringent are being met by a new technic involving sol. as well as insol salts.

Treatment of water prior to filtration. Wellington Donaldson. *3rd Ann. Arkansas Water Works Conf.* 1933, 47-50. A general discussion, especially of the treatment of highly turbid waters. The importance of agitation for 5-45 min. after dosing with the coagulant and prior to sedimentation is emphasized.

The Richmond, Virginia, filter plant. Marsden C. Smith. *J. Southeastern Sect. Am. Water Works Assoc.* 3, No. 1, 22 7(1933); cf. C. A. 27, 2229. —The treatment process comprises  $\text{CuSO}_4$  treatment, prechlorination, flocculation, addn. of activated C, sand filtration and  $\text{NH}_4\text{-Cl}$  treatment.

The design and care of rapid-sand filters. A. B. Morrill and W. M. Wallace. *J. Southeastern Sect. Am. Water Works Assoc.* 3, 5-21(1933).

Promiscuous electric grounding on water service pipes and mains. Nicholas S. Hill, Jr., C. F. Meyerherm and M. W. Cowles. *J. Am. Water Works Assoc.* 25, 1418 30(1933). —Electrolysis or electrolytic action due to grounding d. c. or a. c. on water pipe can result in causing corrosion, color, odor and taste. Further study and consideration of the problems of elec. grounding are recommended.

Modern methods of coating and lining pipe. Linden Stuart. *J. Am. Water Works Assoc.* 25, 1431-42(1933).

The technic of lining pipe with bituminous enamel is outlined. Reinforced cement mortar is recommended over bituminous enamel as an external coating. Estd. savings are based on reduction in steel thickness due to the removal of corrosion dangers.

Bituminous pipe coatings. Wm. M. Wallace and James A. Parks. *J. Am. Water Works Assoc.* 25, 1387-417 (1933). The principles of pipe-line corrosion and its prevention are discussed. Of the various types of protective coatings in use the bituminous coating leads in pipes covered. The coal-tar base coating is somewhat more popular than the asphalt-base coating though the latter is considered, in general, superior. A thorough discussion of the 2 includes methods of test and specifications.

Sewage treatment. Paul Hansen. *3rd Ann. Arkansas Water Works Conf.* 1933, 58-62.

Recent developments in sewage treatment. C. A. Emerson, Jr. *J. Southeastern Sect. Am. Water Works Assoc.* 3, 80-8(1933).

Progress in sewage treatment. Marvin C. Nichols. *3rd Ann. Arkansas Water Works Conf.* 1933, 54-8. —His-

torical material and recent developments with a comparison of present types of treatment on the basis of percentage decrease of suspended matter and of biochem. O demand.

Machinery for dealing with sewage. H. R. Lupton. *Engineering* 136, 396-8 (1933).

Chemical stabilization of sewage. Harrison Hale. *3rd Ann. Arkansas Water Works Conf.* 1933, 50-4. General.

Control of the direction of currents in sewage aeration basins. W. Husmann. *Techn. Gemeindeblatt* 36, 229-31 (1933).

Purification of sewage by natural processes. W. E. Adeney and A. G. G. Leonard. *Engineering* 136, 423-4 (1933).—The satisfactory disposal of normal crude sewage liquors includes: (1) the removal of the coarse solid impurities in the form of sludge by mech. sedimentation; (2) the removal of the solid impurities remaining in fine suspension and in the colloidal state by means of the activated sludge process; (3) biochem. purification, under anaerobic conditions, in digestion tanks of the mixed solid impurities removed by the above 2 methods of sepn.; (4) the biochem. purification, under aerobic conditions, of the org. and ammoniacal impurities remaining in the true soln. in the effluents from the activated-sludge tanks, either through the agency of filter beds or by adequate diln. in streams. The biochem. destruction of org. matter is essentially one of oxidation; under aerobic conditions it is effected by bacteria utilizing the  $O_2$  dissolved in the contaminated liquors, while under anaerobic conditions the purification is effected at the expense of the  $O_2$  contained in the reducible  $O_2$  compds. present. Extn. and analysis of gases from polluted waters undergoing self-purification show 2 distinct stages.  $CO_2$ ,  $NH_3$ ,  $H_2O$  and colored nitrogenous org. products with the properties of the humus of peat are products of the first stage of fermentation.  $NH_3$ , humus, and any  $NH_3$  originally present are oxidized to nitrates and carbonates during the second stage of fermentation. Degree of diln. is important as availability of  $O_2$  is a limiting factor for purification. C. B. J.

Circulation of sewage sludge. O. Herb. *Techn. Gemeindeblatt* 36, 233-5 (1933).—A review of the literature indicates that there is much contradictory data on the advantages of circulating digesting sludge. A lab. expt. in which 2 flasks of the same sludge of initial  $pH$  5.5 were incubated at  $37^\circ$ , flask A being shaken 3 times daily and flask B not at all, indicated that the unshaken sludge digested much faster (as measured by gas evolution) than the shaken sludge. A reached a  $pH$  of 7.8 after 14 days, 8.2 after 18 days; B became alk. only after 2 months. In both cases the gas evolved was 85%  $CO_2$ . M. G. M.

Troubles due to sewage in rivers. Mahr. *Gesundh.-Ing.* 56, 498-501 (1933); cf. C. A. 26, 1367.—Factors detg. the min. permissible diln. of sewage when discharged into a stream are discussed, including freshness of the sewage (biochem. O demand), extent of surface of the water (hence sunlight, air, etc.), rate of flow of the stream, and plant and animal life present in it. Data (biochem. O demand, diln., etc.) are given for a no. of German cities, which include all types of sewage treatment. A graph is given from which the min. permissible diln. can be approx. detd. from biochem. O demand and *vice versa*, the extent of sewage treatment required (resulting biochem. O demand) when a given diln. is possible.

Control of pollution of the atmosphere. G. Batta and E. Leclerc. *Bul. soc. chim. Romania* 15, No. 12, 13-38 (1933).—The toxicity of harmful gases in the atm. arising from industrial and domestic sources decreases in the following series:  $H_2SO_4$ , HF,  $SO_2$ ,  $NO_2$ , CO and  $CO_2$ . Methods for their detn. are given. A method is given for comparing solar luminosities at different times (and

hence measuring roughly the dust in the atm.) by the bleaching effect of the sun's rays on a methylene blue soln. W. A. Mjore

The application of fumigants to ships and warehouses.

I. Distribution of ethylene oxide in empty warehouses.

II. Distribution of hydrogen cyanide in empty warehouses.

III. Penetration of hydrogen cyanide into bags of raw cacao stacked in piles of different sizes. A. B. P.

Page and O. F. Lubatti. *J. Soc. Chem. Ind.* 52, 309-10T, 316-23T, 323-6T (1933).

Observations on the examination of swimming-bath water. J. A. B. Hicks, R. J. V. Pulvertaft and F. R.

Chopping. *Brit. Med. J.* 1933, II, 603-6. J. B. B.

Filtration of oil from boiler feed water (Johnson) 28. Evapn. and its application [to the treatment of natural waters] (Lafitt) 13.

Purification of water with use of activated carbon. Millard Brandt (to Darco Corp.). U. S. reissue 18,967, Oct. 10. A reissue of original pat. No. 1,781,314 (C. A. 25, 158).

Apparatus for purifying water by freezing. Norman H. Gay. U. S. 1,931,347, Oct. 17. Various structural and operative details are described.

Treating hard waters. Gustav Rittler. U. S. 1,930,885, Oct. 17. To purify it and remove easily sol. compds., hard water is treated with  $H_3PO_4$ , and  $NH_4OH$  is subsequently added, and an alk. earth hydroxide is used to remove any excess  $H_3PO_4$  which may be present.

Treating liquids such as water to effect softening and clarification. Wilson Evans (to National Aluminate Corp.). U. S. 1,930,792, Oct. 17. The liquid under treatment is mixed with a preformed product formed from lime, soda ash and  $AlCl_3$  and the resulting ppt. is sepd.

Regenerative water-softening apparatus. Tord E. D. Bildt (to Aktiebolaget Filtrum). U. S. 1,929,405, Oct. 10. Various structural, mech. and operative details are described.

Apparatus for softening water with zeolites. Robert O. Freund. U. S. reissue 18,970, Oct. 17. A reissue of original pat. No. 1,783,466 (C. A. 25, 369).

Base-exchanging clays. Aktiebolaget Filtrum. Brit. 395,185, July 13, 1933. Naturally occurring base-exchanging clays are treated successively with a soln. of a neutral salt such as  $CaCl_2$  and with a soln. of water glass, whereby an insol. ppt. is formed which stabilizes the clay during its use for softening  $H_2O$ . A treatment with a soln. of water glass may precede treatment with  $CaCl_2$ . The raw clay, e. g., natrolith, may be burnt 7 c. g., at  $700^\circ$ , previous to the treatments.

Base-exchanging siliceous gel. Abraham S. Behrman (to General Zeolite Co.). U. S. 1,930,503, Oct. 17. In forming a "whole volume base exchanging gel" from  $Al_2(SO_4)_3$  and Na silicate, reaction between a strong acid such as  $H_2SO_4$  and a strong base such as NaOH is effected simultaneously with the zeolite-forming reaction.

Use of ferric chloride with a smaller proportion of antimony pentachloride as a coagulant for sewage treatment, etc. Ray H. Boundy and James L. Amos (to Dow Chemical Co.). U. S. 1,930,448, Oct. 10.

Artificially heating sewage sludge digestion chambers. Max Pruss. U. S. 1,930,457, Oct. 10. The fresh sludge is heated, prior to its regular introduction into a digestion chamber, to above the desired temp. of the chamber, thereby equalizing in the chamber at its introduction the heat losses toward the outside, and there is regularly supplied to the chamber, between each 2 long periods of regular introduction of heated fresh sludge, digestion-chamber water which has been previously drawn off from the chamber and heated above the temp. desired in the chamber. App. is described.

## 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

**Chemistry and agriculture.** Alexander Lauder. *Chemistry and Industry* 1933, 771 7, 792 7(1933). E. H.

**Review of the work of the Alaska Agricultural Experiment Stations 1898 to 1932.** H. W. Alberts. *Rept. Alaska Agr. Expt. Stations* 1931, 1932, 1 8(1933). Summary of agr. research in Alaska. C. R. Fellers

**The relations between agricultural chemistry and industrial chemistry.** Rudolf Trnka. *Chimie & Industrie Special No.*, 1214 16(June, 1933).—A brief discussion, dealing more particularly with fertilizers. A. P.-C.

**Report of the imperial agricultural chemist.** J. N. Mukerji. *Imp. Inst. Agr. Research Pusa, Sci. Repts* 1931 32, 97-112(1933); cf. *C. A.* 26, 5365.—*Curing of tobacco*—When tobaccos were cured on racks in the sun protected from dew the nicotine content was invariably higher when the stalks were left attached to the leaves than when they were removed. *Potato storage expts.*—

Respiration of potatoes was stimulated by storage at 37°; the respiration ratio ( $\text{CO}_2$  evolved/O absorbed) increased to 1.1 in 4 days, but thereafter the  $\text{CO}_2$  evolution was far greater than the O absorption. Respiration was decreased by storage at 10 15°; the respiration ratio reached unity in 7 days and remained constant thereafter. At 37° the tissue injury known as "black-heart" occurred after 4 days, the catalase activity and O absorption simultaneously decreased and practically ceased in 12 days. At 10 15° very little injury to the tissue occurred even after 24 days; catalase activity increased considerably for the 1st 9 days and remained high till the end of the expt. (23 days). *Alkali soil investigations.*—The solonch soils from the kalar area of Sakrand (Sind) were studied. A hard pan layer rich in gypsum but not unusually high in alkali occurs at a depth of 18.5 24.5 in. The soil is high in Ca and Mg carbonates which tend to concentrate in the subsurface layers; the sum of the HCl-sol  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$  remains uniform over the whole profile. Ca is the predominating exchangeable base, and the av. ratio of univalent to bivalent ions is 0.36. *Disintegrated bones,* prepared by treating raw bones with a soln. contg. 1.5% NaOH and 1% NaCl in air-tight vessels for 2 months, were more effective than either bone meal or bone superphosphate in increasing the growth of *marua* on a P-deficient soil. *Nitritation of apricot seed cake.*—The cake contained 6.5% N, 63% of which was converted into  $\text{NH}_3$  and nitrates in 8 weeks in both calcareous and noncalcareous soils. Accumulation of  $\text{NH}_3$  was greater in the calcareous than in the noncalcareous soil. Different methods for detg. the lime requirement of acid soils gave widely varying results on Indian soils, and the order of the results was different with different types of soil. In expts. on soils desalted by leaching with dil. HCl, washing free from acid and drying, there was no relation between the amt. of lime water required to bring the soil to a definite  $\text{pH}$  value and the lime requirement as detd. by several well-known lime-requirement methods.

K. D. Jacob

**The brown forest soils of England.** G. R. Clarke. *Forestry* 7, 43 7(1933).—The A horizon is characterized by its high content of humus; free  $\text{CaCO}_3$  is rare and, compared to the B horizon, it is poorer in soil material and clay, although it always contains exchangeable Ca. The B horizon is characterized by the uniform distribution of brown, well-oxidized Fe compds.; little or no humus material is present;  $\text{CaCO}_3$  may occur toward the bottom of the horizon. The C horizon consists of weathered parent material. In soils derived from heavy clays or under the influence of a high water-table, a gley horizon may occur within the zone of fluctuation of ground water; it is characterized by the blue-green varnish, due to Fe compds. in various stages of oxidation and hydration, on the faces and edges of the structural elements, concretions, specks and flakes of Fe oxides occur upon the structural elements, while grains and dendrites

of  $\text{MnO}_2$  are often widely distributed throughout the upper portion of the horizon. K. D. Jacob

**The red Mediterranean soils of France and their mother rocks.** V. Agafonoff. *Compt. rend.* 197, 693 5 (1933).—The red Mediterranean soils of France are

derived from calcite and dolomite which contain less than 1.5% insol. in HCl. The soils contain 3.43 5.09%  $\text{Fe}_2\text{O}_3$ ; loss at 105 110°, 2.39 2.63%; loss on ignition, 7.65 7.80%. These soils constitute an independent sub-type in the Mediterranean region. G. M. P.

**The soil erosion problem in New Jersey.** Linwood L. Lee. *J. Am. Soc. Agron.* 25, 652 60(1933). J. R. A.

**Interrelationships of soil and forest cover on Stat Island, Minnesota.** F. J. Alway and P. R. McMiller. *Soil Sci.* 36, 281 95(1933).—A study, is made of forest cover and soil of 4 forest types: jackpine, Norway pine, white pine and maple-basswood. The maple-basswood areas are least acid and richest in lime. Norway pine areas are usually the most acid. The chem. compn. of the forest floor material varies considerably with the season when collected. Samples taken in October contain much more volatile matter than those taken in August. The N contents of the forest floor and of the surface 3 in. of soil vary with the kind of trees and are highest for maple-basswood. As a rule, when the  $\text{pH}$  of the forest floor is below 5.1 the underlying soil is less acid, whereas elsewhere it is more acid. M. S. Anderson

**Chemical studies on Appalachian upland podzol soils.**

**I. Conditions governing base-exchange relations.** G. T. Shaw and R. R. McKibbin. *Can. J. Research* 9, 386-95 (1933). The base-exchange properties and the con-

stituent materials of the base-exchange complexes of Quebec Appalachian upland podzol soils have been studied. It has been shown that the "availability" of the acid semihumified org. matter has played the most important part in bringing about existing conditions in these soils. Org. matter is dominating the processes through which the podzol soils pass in their progress from a slightly leached to a severely leached condition. The morg. base-exchange complexes are superseded by org. complexes. The more "available" Fe and Al present in these soils, the less is their base-exchange capacity. The morg. base-exchange complexes are unstable under the strongly acidic soil conditions. The restoration of fertility to these soils must be approached through modification of the org. matter conditions. J. W. Shipley

**A sensitive hydrometer for estimating total solids in irrigation waters and soil extracts.** Amar Nath Puri. *Soil Sci.* 36, 297 301(1933); cf. *C. A.* 26, 4666.—A sensitive hydrometer is described which is suitable for testing the approx. quality of irrigation waters. Exptl. results show that the hydrometer readings of clear soil exts. are practically a linear function of the total solids in soln. In the field it is possible with this instrument readily to classify waters into 3 groups, good, medium and bad. M. S. Anderson

**The laws of soil colloidal behavior. XIII. Osmotic imbibition.** Joseph G. Falconer and Sante Mattson. *Soil Sci.* 36, 317 27(1933); cf. *C. A.* 26, 4664.—A study is made of the relationship between pressure and the  $\text{H}_2\text{O}$  content of bentonite. Electrolyzed bentonite retains much less  $\text{H}_2\text{O}$  at various pressures than does the natural product. The electrolyzed product not air dried after first dispersed retains much more  $\text{H}_2\text{O}$  than is retained by the same product after air-drying. Bentonite satd. with Mg retains about the same amt. of  $\text{H}_2\text{O}$  as the H-satd. material and the Ca product behaves similarly. K-satd. material retains more  $\text{H}_2\text{O}$  and Li-satd. material much more  $\text{H}_2\text{O}$  than the electrolyzed material. The product  $V \sqrt{P}$  is a const. whose magnitude depends on the nature of the exchangeable cation. In this expression  $V = \frac{1}{100} \times \frac{\text{cc. of } \text{H}_2\text{O per g. of dry bentonite and}}$

$P$  = pressure applied. When 0.5  $N$   $Na_2SO_4$  is used instead of  $H_2O$ , the value for the const. is lowered, and this value is still further lowered when 0.5  $N$   $NaCl$  is used.

M. S. Anderson

**Humic acid considered as the cause of the electrochemical activity of soil.** Jaroslav Kuběš. *Chimie & industrie Special No.*, 1205 7 (June, 1933). From a discussion of the literature on the effect of lignites and humus on soils, K. considers that their action is probably due to formation of insol. humates which coat the soil particles, preventing them from agglomerating into a compact mass and maintaining the soil in a loose porous condition; they also probably give rise to electrochem. phenomena through which nutritive elements which are present in insol. form are solubilized and rendered available to the plants.

A. Papineau-Couture

**Comparison of the Neubauer method with the results of growing tests carried out in Moravia in 1926 1931.** Otto Kyas. *Chimie & industrie Special No.*, 1217 41 (June, 1933). Neubauer's method was applied to Moravian soils, with which accurate field tests were carried out to det. their requirements of nutritive substances. The tests were carried out over a no. of yrs. on soils of various mech. textures and suitable for the cultivation of wheat and potatoes and as prairies. In the cases where Neubauer's physiol. method indicated a lack of nutritive substances (K,  $P_2O_5$ ) the field tests showed that in most cases when fertilizers were added in amts. sufficient to bring the K and P contents of the soil above the crit. values, as detd. by the Neubauer method, the crops increased, but in some cases no increase was noted. It is concluded that, in order to obtain remunerative crops on Moravian soils, the amt. of fertilizers (particularly K) added to the soil should be greater than the crit. amt. as detd. by the Neubauer method, or else the amt. required should be detd. directly by field tests.

A. Papineau-Couture

**Some factors limiting the applicability of biological methods for determining the availability of plant food elements in calcareous soils.** Robert A. Greene. *Soil Sci.* 36, 201 6 (1933). The *Azotobacter* method for detg. the availability of phosphates in soil is of little value on calcareous soils. However, if a soil of high  $pH$  is well aerated, *Azotobacter* will develop and by the production of  $CO_2$  and org. acids will lower the  $pH$  of the soil sufficiently to permit the absorption of phosphate. This test for P availability is most successful in soils which are extremely deficient in P.

M. S. Anderson

**The importance of calcification and its technic.** Buchinger. *Mitt. deut. Landw.-ges.* 48, 174 6 (1933). The importance of applying Ca to soil regularly in small amts. is emphasized.

B. C. Brunstetter

**The accumulation and availability of phosphorus in old citrus grove soils.** O. C. Bryan. *Soil Sci.* 36, 245 59 (1933). A study is made of the total, available, and  $H_2O$ -sol. forms of P in the soils of citrus groves. Each of these forms of P increases with age of the groves where customary fertilization is used. The accumulation of sol. P is much greater than in other humid soils. This is due to the low P-fixing power of sandy soils and to the low P requirements of citrus trees. Leaching and plant response studies show a much greater movement of P fertilizers in Florida soils than in California. The optimum concn. of P in the soil soln. for citrus growth is not known, but it appears that the amt. accumulated in the soil from fertilization is in excess of that needed.

M. S. Anderson

**Rational utilization of phosphoric acid in the growth of plants.** Ad. Tilp. *Chimie & industrie Special No.*, 1245 6 (June, 1933).  $P_2O_5$  incorporated into arable soils is generally utilized only to the extent of about 15%. The balance can be rendered available for plants by addn. of very finely ground  $SiO_2$ .

A. Papineau-Couture

**Factors affecting the phosphoric acid-phosphate rock reaction.** H. L. Marshall, L. F. Rader, Jr. and K. D. Jacob. *Ind. Eng. Chem.* 25, 1253 9 (1933). Representative phosphate rocks were treated with reduced

$H_2PO_4$ . Max. conversion of the  $P_2O_5$  to available forms without heating was obtained with acid contg. 64% of  $H_2PO_4$  and storing for 4 days or longer. Almost complete conversion was obtained when the temp. of the mixt. was held at 60° during stirring followed by storage for 2 days. The quantity, concn. and purity of the acid, the type and particle size of the rock and the time of mixing were of varying degrees of importance. K. C. Beeson

**Phosphate rock.** Bertrand L. Johnson. *U. S. Bur. Mines, Minerals Yearbook 1932-33*, 701-7 (1933). A. H. E.

**The availability and downward movement of rock phosphate in Illinois soils when used liberally for 25 to 30 years and influence of the treatment on available potash and total nitrogen.** A. U. Thor. *J. Am. Soc. Agron.* 25, 661 74 (1933). The study was made on the soils of 3 Illinois corn belt farms, on all 3 of which rock phosphate has given satisfactory results. The soils of the Mies and Mann farms are brown silt loams, and the soil of the Hopkins farm is a gray silt loam. The amts. of sol. P on the Mies, Mann and Hopkins farms have been increased 370, 217 and 224 lb. per acre, resp., through the addn. of rock phosphate. On the open-textured soils there was an appreciable downward movement of P into the 8 to 16 and 16 to 24 in. depths. On the more compact soil there was a definite movement into the 7 14 in. depth but only a slight movement into the 14-21 in. depth. The amt. of P recovered by weak acid extr. plus that removed by crops accounts for 90% or more of the total applied. The use of limestone has reduced the acidity to a marked extent in the plowed layer and to a slight degree in the subsurface and subsoil strata. Applications of rock phosphate on the Hopkins farm appear to have reduced acidity slightly. The use of lime and rock phosphate with the growing of legumes regularly in the rotation has apparently increased the amts. of available  $K_2O$  and total N in the surface soil of the Hopkins and Mies farms.

J. R. Adams

**Relation of Pythium to growth failure on phosphate-fixing soils.** D. A. Cooke. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 169 78. In Mitscherlich pot tests certain Hawaiian soils fixed all the  $P_2O_5$  added, and 3 7 times the normal dose had to be given for max. growth. Small quantities of chloropicrin gave the same result as high  $P_2O_5$ . The chloropicrin brought about no chem. or phys. change in the soil, and it did not stimulate plant growth directly. Nematodes and protozoa were not affected by it. It was finally found that the chloropicrin destroys the cane root rot fungus *Pythium aphanidermatum*. The similar effect of phosphate is explained by the stimulation and strengthening of root growth. The use of chloropicrin or large phosphate applications would be too expensive in practice, but the planting of varieties resistant to *Pythium* would be feasible on such soils. This should be combined with applications of  $P_2O_5$  near the roots of the cane. Mixing with the soil should be avoided to prevent fixation.

F. W. Zerber

**Availability of iron, aluminum and other phosphates.** R. P. Bartholomew and K. D. Jacob. *J. Assoc. Official Agr. Chem.* 16, 598 611 (1933); cf. Ross, J. and Beeson, C. A. 26, 4404. The availability of synthetic and natural  $AlPO_4$ ,  $FePO_4$ ,  $MgHPO_4$ ,  $Mg_3(PO_4)_2$ ,  $MgNH_4PO_4$ ,  $K_2P_2O_7$ ,  $Ca_3P_2O_7$ ; K and Ca metaphosphates, superphosphate and  $CaH_2(PO_4)_2$  was detd. by chem. methods, production of plant material and absorption of P by plants. The Mg phosphates, synthetic  $AlPO_4$ , unignited  $FePO_4$ , K meta- and pyrophosphates, and  $CaH_2(PO_4)_2$  are completely or nearly completely sol. in neutral  $NH_4$  citrate soln. according to the official A. O. A. C. method of analysis. Ignition increases the citrate soly. of natural hydrated  $AlPO_4$  and decreases the soly. of synthetic  $FePO_4$ , but has no effect on the soly. of synthetic  $AlPO_4$ . The citrate soly. of ignited  $AlPO_4$  and ignited  $FePO_4$  increases with increase in the wt. of sample taken for analysis; the reverse is true with unignited natural  $AlPO_4$ . The relative efficiencies in production of increased growth of Sudan grass, as compared with  $CaH_2(PO_4)_2$  as 100, are: ignited natural  $AlPO_4$ , 106.5,  $MgNH_4PO_4$ , 105.0,  $Mg_3-$

( $\text{PO}_4$ ), 94.3, unignited synthetic  $\text{AlPO}_4$ , 93.6, ignited synthetic  $\text{AlPO}_4$ , 42.8, ignited  $\text{FePO}_4$ , 27.1, unignited  $\text{FePO}_4$ , 8.4. The  $\text{P}_2\text{O}_5$  of unignited synthetic  $\text{AlPO}_4$ ,  $\text{MgHPO}_4$ ,  $\text{Mg}_2(\text{PO}_4)_3$ ,  $\text{MgNH}_4\text{PO}_4$ , K metaphosphate and  $\text{K}_2\text{P}_2\text{O}_7$  is absorbed more readily by plants than the  $\text{P}_2\text{O}_5$  of  $\text{CaH}_2(\text{PO}_4)_2$ ; for the other phosphates, the relative increases in the amts. of  $\text{P}_2\text{O}_5$  absorbed by the plants, compared to  $\text{CaH}_2(\text{PO}_4)_2$  as 100 are:  $\text{FePO}_4$ , 98.3, ignited synthetic  $\text{AlPO}_4$ , 83.5, ignited natural  $\text{AlPO}_4$ , 71.3, unignited natural  $\text{AlPO}_4$ , 52.5, ignited  $\text{K}_2\text{P}_2\text{O}_7$ , 50.7. In general, the relative availabilities of the phosphates, as detd. by the citrate method, are in good agreement with their relative fertilizer efficiencies as indicated by plant growth and absorption of  $\text{P}_2\text{O}_5$ . On the basis of the total amt. of dry matter produced, the only outstanding exceptions are the low value assigned to unignited  $\text{FePO}_4$ , which was completely sol. in citrate soln., and the high value assigned to ignited natural  $\text{AlPO}_4$ . The results, on the basis of the amt. of  $\text{P}_2\text{O}_5$  absorbed by the plants, also agree with the availability shown by chem. analyses, with the exception of ignited synthetic  $\text{AlPO}_4$  and the unignited natural  $\text{AlPO}_4$ . The results, as a whole, show that the neutral  $\text{NH}_4$  citrate test gives a reliable index of the fertilizer value of the  $\text{P}_2\text{O}_5$  in these particular phosphates. The 2% citric acid method does not give a reliable indication of the fertilizer value of the  $\text{P}_2\text{O}_5$  in Fe and Al phosphates.

A. Papineau-Couture

**Composition of some locally grown [Alaska] forage crops.** F. L. Higgins. *Rept. Alaska Agr. Expt. Stations* 1931 32, 22 3(1933). Cotton sedge, *Eriophorum vaginatum*; bluetop, *Calamagrostis* sp.; native sedge, *Carex aquatilis*, bird vetch, *Vicia cracca*; and brome grass, *Bromus inermis* yielded, resp., upon chem. examn.: lat 1.4 2.0, 1.5 1.8, 1.3 2.2, 1.4 and 1.4; crude fiber 28 34, 32 40, 29 37, 35 5 and 32 7; protein 4 10, 2 6 11 5, 3.7 12.2, 10 7 and 7 6 3; ash 1.6 2.9, 4.2 7.3, 2.0 5.6, 6.6 and 7.3%. The results show that sedges should be harvested during late Aug. and bluetop during late July to obtain max. feeding value.

C. R. Fellers

**The use of alfalfa and other semipermanent cover crops in the orchard.** A. J. Hemmick. N. Y. State Hort. Soc., *Proc. 17th Ann. Meeting* 1932, 59-60; cf. C. A. 26, 5685. Where no N fertilizer was added to the soil, the leaves of apple trees growing on grass plots were lowest in N, while those from trees growing on clover plots were highest; the use of N fertilizers greatly reduced the differences. The N content of the leaves of trees growing on alfalfa and grass plots cut in June was appreciably higher than that of leaves of trees on plots cut in Aug.

K. D. Jacob

**The control of Bermuda grass through the use of chlorates.** H. F. Murphy. *J. Am. Soc. Agron.* 25, 700 1 (1933). Bermuda grass can be controlled by the use of  $\text{NaClO}_3$  or  $\text{Ca}(\text{ClO}_3)_2$ , although the rate of application and cost is such as greatly to limit the size of the area that can be treated. Very good control was secured on both mowed and unmowed grass from the use of either chemical when applied in 2 applications  $1\frac{1}{2}$  months apart, from July 15 to Sept. 3, each application being made at the rate of 200 lb. per acre. For large areas the use of sowed cane or shade crops is to be recommended in Bermuda grass control.

J. R. Adams

**The fixation of atmospheric nitrogen by bacteria living symbiotically in root nodules of *Casuarina equisetifolia*.** R. N. Aldrich-Blake. *Oxford Forestry Mem.* 14, 1 20 (1932); *Rev. Applied Mycol.* 12, 582 3.—The fixation of atm. N by the bacteria occurring as symbionts in the root nodules of *Casuarina equisetifolia* is considered proved by growing uninoculated, inoculated and plants receiving  $\text{NH}_4\text{NO}_3$  under controlled conditions. The dry roots contained 0.96, 1.31 and 0.77% N, resp. The weights of the dry roots were 9.28, 133.5 and 33.83 g., resp.

Oden B. Sheppard

**Some factors influencing nitrogen fixation.** J. B. Graves. *Soil Sci.* 36, 267 80(1933). The N fixed in soil and in Ashby's medium together with soil ext. varies with the character of the soil. The activity of *Azotobacter*

*chroococcum* is greatly enhanced when Mn, Fe and I are added to liquid culture media. These elements appear to be essential to the growth metabolism of this micro-organism. Other elements such as B, Al, Cu, Br, Zn, Ti, Se and Te are non-essential to *Azotobacter*, while Cu and Zn are toxic even in very small amts. A basal medium is suggested which contains Fe, Mn and I and in which *Azotobacter* grows as profusely and fixes as much N as in soil ext. media. It has the advantage of having a definitely known compn.

M. S. Anderson

**Nitrogen mixed fertilizers.** Ernst Galle. *Chimie & Industrie Special No.*, 721-4 (June, 1933).—A brief discussion of the fertilizers recently developed by the I. G. Farbenindustrie: Leunaphos, Nitrophoska, Huminol.

A. Papineau-Couture

**Simple fertilizers or mixed fertilizers.** Rudolf Trnka. *Chimie & Industrie Special No.* 1242 4 (June, 1933).—A brief discussion.

A. Papineau-Couture

**Mixed fertilizers and the sugar beet.** Louis Decoux. *Ind. sacchar. ital.* 26, 460-2(1933).

L. Cusachs

**Production of concentrated fertilizers by decomposition of flotation concentrates with nitric acid and subsequent treatment of the product with ammonium sulfate and ammonia.** I. Kukushkin and A. Morozova. *Khimstrof* 5, 2343-51(1933).—The lab. expts. in the production of mixed fertilizers are based in part on Brit. pat. 232,330 and other patents. Flotation concentrate of apatite was decompd. with  $\text{HNO}_3$ , the reaction mass was treated with tech.  $(\text{NH}_4)_2\text{SO}_4$  and filtered from  $\text{CaSO}_4$ , the filtrate was neutralized with aq.  $\text{NH}_3$  and evapd. to dryness.  $\text{CaSO}_4$  treated with  $\text{NH}_3$  and  $\text{CO}_2$  gave  $\text{CaCO}_3$  and  $(\text{NH}_4)_2\text{SO}_4$ .

Chas. Blanc

**Selection of potash fertilizers for the cultivation of potatoes.** Antonin Némec. *Chimie & Industrie Special No.*, 1247-50 (June, 1933). The use of K fertilizers, particularly those contg. KCl, produces a decrease in the starch content of potatoes grown in soils rich in chlorides; so that with such soils  $\text{K}_2\text{SO}_4$  fertilizers should be chosen. In selecting K fertilizers the compn. of the soil, and more particularly its chloride content, should be taken into consideration.

A. Papineau-Couture

**Determination of potash as perchlorate.** M. Lenglen and Milhiet. *Ann. fals.* 26, 469-70(1933).—The French official method for detn. of  $\text{K}_2\text{O}$  in fertilizers stipulates that the mixed alkali chlorates be taken up in 10 cc. of 95-96% alc. and washed with 3 5-cc. portions. This is likely to give high results, particularly in presence of relatively large amts. of  $\text{NaClO}_4$ , because of incomplete removal of the latter. In order to ensure complete removal of  $\text{NaClO}_4$ , a total vol. of at least 70 cc. of alc. (preferably satd. with  $\text{KClO}_4$  to avoid partial soln. of the  $\text{KClO}_4$ ) should be used.

A. Papineau-Couture

**Use of coal as a fertilizer.** Alexander D. Kissel. *Chimie & Industrie Special No.*, 705 18 (June, 1933).—A review and discussion showing that coals of low caloric value can be used, after suitable treatment, as a supporting material in the manuf. of fertilizers which are characterized by: (1) absence of inert material; (2) a high humic acid content which acts by maintaining the phys. properties of the soil and by the nutritive value of its C content; (3) the presence of nutritive matter in proper proportions.

A. Papineau-Couture

**Dolomite as a fertilizer supplement—its behavior and control.** W. H. MacIntire. *J. Assoc. Official Agr. Chem.* 16, 589 98(1933). A general discussion of the benefits of the use of dolomite as a fertilizer supplement and of the problems which its recognition would involve from a regulatory standpoint.

A. Papineau-Couture

**Effect of fertilizers on irrigated Ephrata fine sand and apple tree response in the Wenatchee orchard district.** C. A. Larson. *J. Am. Soc. Agron.* 25, 633-52(1933).—An attempt was made to discover the effect of various fertilizer treatments on the absorbing complex of the soil and its relation to tree response and yield of fruit. Neither  $\text{H}_2\text{O}$  nor 0.2N  $\text{HNO}_3$  extn. of the soils nor electroanalysis of the soils gave any reliable indications of relative productivity as affected by the fertilizer applications. The

amt of nitrate N<sup>o</sup> contained in the plat soils during the first half of the growing season was rather closely correlated with the actual production of fruit. The H ion concn of the various plat soils showed that combination of N and P and N, P and K increased the acidity of the soil. There appears to be a tendency for Ca, N, P<sub>2</sub>O<sub>5</sub> and K<sub>2</sub>O to be in a definite ratio to each other in the apple leaves when production is good. Plats producing leaves with a relatively low percentage of P<sub>2</sub>O<sub>5</sub> and a high percentage of N gave an increased yield. Where N has been applied alone or in combination with other fertilizers, yield has increased. J R Adams

The shielding effects of various materials when insects are exposed to lines of force in a high frequency electrostatic field. Louis Pycn on *J N Y Entomol Soc* 41, 241-52(1933). The lethal effect of line of force in a high-frequency electrostatic field is limited in solid dielectric, by the moisture content, in pure liquid by the dielectric const. Liquid or solid conductors act as shields to insects when they are exposed to lines of force between the plate. The expts show that insect may be destroyed in many substances without injuring them. The substances are chiefly soils contg a limited amt of moisture, woody materials, tobacco seeds, breakfast foods, clothes, flours, cellulose compd and nuts. C H Richardson

Report of the imperial agricultural bacteriologist N V Joshi. Imp Inst Agr Research Pn 1 *Sci Repts* 1931 32, 116-53(1933) of *C I* 26, 331. *Antitoxin of cyanamide*. When cyanamide is added to certain Indian soils no accumulation of nitrate occurs after incubation for 20 weeks although fairly large amt of NH<sub>3</sub> accumulate in 2-3 weeks. Complete nitrification of the cyanamide occurs however, in 6-71 weeks. The delay in nitrification is due to the formation of diacyl diureide which is toxic to nitrifying bacteria and which persists in these soil for an unusually long time. The fact that nitrification eventually occurs indicate that the diacyl cyanodiamide does not kill the nitrifying organism. *Preservation of vegetables*. Lactic bacteria are normally present on *kakri* (1 of the cucurbits) but not on late cabbage. The formation of acid when cabbage is preserved in salt soln is due to the presence of epiphytic flora. K D Jacob

Progress report on vegetable diseases. IV. I. Oulvin and B O Mulligan. Univ Bristol Agr Hort Research Sta. *Ann Rept* 1932 103-20 of *C I* 27, 43. Satisfactory control of *bot ro of peas* caused by *Myco. phaeella pinodes* and *Ascochyta blight* was obtained by dusting the seed with Cresan (C<sub>2</sub>H<sub>5</sub>OH) or dipping in KMnO<sub>4</sub> soln (1 oz/gal) for 20 min. The Cresan treatment tended to preserve the cotyledons in a firm state for a long time. The treatments did not adversely affect germination. K D Jacob

Methods of testing plant protectives. IV VI. K. Gornitz, W. Trappmann, G. Nitsche and H. Voelkel. *Mitt. Biol. Reichsanst. Land- und Forstwirtschaft* 46, 1-11 (1933). *Rev. Appl. Mycol.* 12, 577. A contrivance is described for detg. the dosage of spray or dust materials deposited on the leaf surface. The mode of testing plant protectives for their resistance to washing off by rain is explained. The maintenance of permanent cultures of *Plasmopara viticola* in the inoculation of vine leaves on which to test the efficacy of new fungicides is discussed. Oden I Sheppard

Comparative laboratory tests on the fungicidal effect of colloidal and non colloidal material. W. Niggl. *Gesundheitsuch. Studtehyg.* 25, 45-50(1933). Data on colloidal and non colloidal BaSO<sub>4</sub> preps show that the fungicidal effect of a salt may be considerably increased when it is acting in the colloidal state. B C B

Pyrethrum and its derivatives. J H Irvy. *Ind. Eng. Chem. Anal. Ed.* 36, 161-65(1933). A review of these products and their use in insecticides. P I

The valuation of tuba root. C D A. George and Cunn. *Malay State. Ser. Ser. No. 12*, 0 pp (1933). *C I* 1

27, 1443. An attempt is made further to standardize the approximation of the 2 methods of valuation of tuba roots, i.e., amt of material extd with a solvent for the amt of rotenone present. This standardization covers selection of sample, prepn of root for analysis, detn of moisture, detn of solvent ext and detn of rotenone. The moisture content of the air dry root varies from 7 to 10% and can be detd by drying finely ground material to const wt in a steam oven at 100° or by distn with xylene. The latter gives slightly higher results and is preferable. The amt of extractable material is customarily detd by extn with ether for 48 hrs. The ether may be replaced by CCl<sub>4</sub>, acetone or CHCl<sub>3</sub>. A modification of the Roark method for detn of rotenone is suggested in which a few crystals of pure rotenone are introduced into the concd ext to insure satisfactory sepn of the rotenone. It was also found advisable to purify the rotenone by recrystn from alk before weighing. Ether was found unsatisfactory for the extn of the rotenone and can be replaced advantageously by either CCl<sub>4</sub> or CHCl<sub>3</sub>. Figures on both *Derris malaccensis* and *Derris elliptica* show that while the endodermic portion of the root is rich in both rotenone and ether ext than the outer th difference is insufficient to require preliminary sepn of the roots into constituent parts. J R A

The determination of the adhesiveness of dusts to treated cereal seed grain in the supervision of cooperative disinfection plants. G. Friedrichs. *Nachrichtbl. Deut. Pflanzenkrankheitsdienst* 13, 36-7(1933). *Rev. Appl. Mycol.* 12, 558-9. A colorimetric method of testing disinfectant dust for their adhesive capacity based on the admixt with the fungicidal substance of a dye which, on slightly moistening the cereal seed grain, colors the latter to a varying degree according to the amt applied is described. Winkelmann (*C I* 26, 805) suggested the method. Oden I Sheppard

Tests of certain dusts and ready made sprays for the control of potato blight in comparison with Burgundy mixture. Paul A. Murphy and Robert McKay. *J. Dept. Agr. Ireland* 32, 30-35(1933). In a 4 yr expt. spraying with 2 Burgundy mixt was more effective than spraying with Pimol (a proprietary colloidal suspension of an insol complex Cu compd contg 12.5% Cu) or bluing with hydrated CuSO<sub>4</sub> powder or Cu lime dust. Burgundy mixt checks the late growth and hardens the plant. K D Jacob

Orchard sprays in New Zealand. VI. The nicotine series. G. H. Cunningham. *New Zealand J. Agr.* 47, 131-10(1933) of *C I* 27, 5877. The chemistry, prepn and use of nicotine sprays are discussed. Twenty references. K D Jacob

Combined insecticide fungicide sprays for apples. Progress report. H. G. H. Kearns, R. W. Marshall and I. P. Pearce. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932 66-83. Oil emulsions contg 65-70% oil (Shell P2) and 20-30% water are easily prepd by the addn of 5% of sulfite liquor. The emulsion is stable toward lime S mixts and hard waters, does not set to stiff jelly and is easily diluted with water. Nicotine is compatible with emulsions of oil and lime S prepd in this manner and the result of preliminary expts indicate that the alkali of the lime S is sufficient greatly to reduce the risk of foliage injury when Ca arsenate is added to such spray. Lime S plus nicotine and a wetting agent applied on Worcester apples at the petal fall stage, gave prompt result for the simultaneous control of scab and sawfly. K D Jacob

Trials with a colloidal copper spray fluid. R. W. Marshall. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932 84-9. Favorable results were obtained with Bousof (a colloidal Cu spray material contg 12.5% Cu) for the control of scab on the Stirling Castle and Lane's Prince varieties of apples which cannot be sprayed safely in the summer with either lime S or Bordeaux mixt. The spray also reduced scab and increased foliage retention on black current, without leaving a significant amt of residue on the berries. K D Jacob

Further observations on the control of the apple sawfly, *Holocampa testudinea* (Klug.). H. G. H. Kearns and T. Swarbrick. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 90-4; cf. *Ibid.* 1931, 112.—Efficient control of the larvae on Worcester Pearmain apples was obtained by spraying the fruitlets with a nicotine wash (8 oz. nicotine, 2.5 lb. Agral I and 100 gal. water) between the 6th and 12th days after petal fall. Similar results were obtained with a rape oil-derris emulsion; a derris soap wash (0.004% rotenone) gave fairly good control. Pyrethrum emulsion (representing a concn. of 0.5% of the flowers) and colloidal Pb arsenate sprays reduced the infestation by 50%. K. D. Jacob

Control of the greenhouse Symphylid (*Scutigerella immaculata*). H. G. H. Kearns and C. L. Walton. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 97-101.—Treatment of infested greenhouse soil *in situ* with cresylic acid emulsion was ineffective in controlling the pest. Good control was obtained by heavily watering the soil with HgCl<sub>2</sub> soln. (1:25,600). K. D. J

Control of strawberry leaf roller on bearing plants. Ray Hutson. Mich. Agr. Expt. Sta., *Quart. Bull.* 16, 78 (1933).—Three sprays, spaced a week apart, resulted in 85-90% control of *Ancylos complana*. The spray consisted of a combination of nicotine sulfate, 1 pint; summer oil emulsion, 1 gal.; and activated pyrethrum dust applied at the rate of 50 lb. per acre. C. R. Fellers

Control of hard rot of strawberry fruits. L. Ogilvie. Univ. Bristol Agr. Hort. Research Sta., *Ann. Rept.* 1932, 102. Good control of the disease, which is caused by the fungus *Septoria fragariae*, was obtained by spraying the plants with 5% tar oil emulsion or with Bordeaux mixt. K. D. Jacob

Baits for the control of certain cotton pests. D. O. Atherton. *Queensland Agr. J.* 40, 183-90 (1933).—Molasses and honey baits contg. Na arsenite, kerosene, AmOAc or EtOAc were ineffective against the corn ear worm (*Heliothis obsoleta* Fabr.). A sirup of molasses and water contg. Na arsenite (0.5 oz./gal.) showed promise as a bait for the cotton looper moth (*Antarchaea chonosticta* Turn.). K. D. Jacob

Fruit scald and leaf scorch. W. D. Mills and W. B. Blauvelt. N. Y. State Hort. Soc., *Proc. 77th Ann. Meeting* 1932, 17-24. No correlation existed between the amt. of fruit scald on Baldwin apples and the various S spray and dust material applied. More or less scald followed the use of lime-S at various dilns., dry lime-S, lime S and Fe sulfate, and S dust, all of which contained Pb arsenate. Scald did not occur with Bordeaux mixt. Combinations contg. lime-S with Pb arsenate most frequently caused leaf scorch, and addns. of Fe sulfate and Ca(OH)<sub>2</sub> did not prevent injury, in general, S dusts caused but little leaf scorch. K. D. Jacob

Oil from the seeds of *Tectona grandis* (Puntambekar, Krishna) 27. Peanuts [plant as green manure] (Cross) 12. Fertilizers (Ger. pats. 579,627-8-9) 18.

Arnold, Lionel K: Utilization of Agricultural Wastes and Surpluses. Ames, Ia.: Iowa State College. (Bull. 113, Eng. Extension Service.) 31 pp.

Fertilizer. Silas J. Smith. U. S. 1,930,542, Oct. 17. A mixt. is formed from moist fibrous material such as peat and sol. fertilizer material such as (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> or NaNO<sub>3</sub>, and this mixt. is heated to dissipate moisture from the fibrous material in the form of steam and cause the sol. fertilizer to dissolve and penetrate the fibrous material.

Fertilizer. Charles Peter. U. S. 1,931,296, Oct. 17. Fine rock phosphate, fine lime rock and fine salt are mixed, and the mixt. is roasted at about 315-425° for about 30 min. A mixt. of fine coal and fine salt is separately roasted at about 175-315° for about 30 min. The two resulting mixts. are combined with each other and with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>.

Fertilizers. Kali-Forschungs-Anstalt G. m. b. H.

(Hans Friedrich, inventor). Ger. 569,151, Sept. 26, 1933. Solns. contg. K<sub>2</sub>SO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, NH<sub>3</sub>, and CO<sub>2</sub>, such as are obtained in the processes of Ger. 478,988 (C. A. 23, 4782) and 497,611 (C. A. 25, 503-4), are heated to remove NH<sub>3</sub> and CO<sub>2</sub>, treated with HNO<sub>3</sub> or nitrous gases, and then used for the treatment of crude phosphate. The resulting soln. is concd. and the cryst. product is dried in a stream of NH<sub>3</sub>. Other fertilizers may be mixed with the product before or after drying.

Fertilizers. Franz Haniel & Cie. G. m. b. H., Zweigniederlassung Mannheim. Fr. 750,638, Aug. 14, 1933. A humous fertilizer capable of dispersion is made by injecting an aq. fertilizer under pressure into a chamber contg. a finely divided peaty mass in suspension. Agents acting to exterminate harmful insects may also be injected.

Mixed fertilizer. Hermann Ochme and Ernst Herrmuth (to Chemische Fabrik Kalk G. m. b. H.). U. S. 1,930,883, Oct. 17. In producing a mixed fertilizer contg. Ca phosphate and N, decompn. products such as may be obtained from raw phosphates by treating them with acid are first treated with dil. NH<sub>3</sub> and then with concd. NH<sub>3</sub> with simultaneous addition of such a quantity of water that on complete or substantially complete satn. with NH<sub>3</sub> a directly strewable mixed fertilizer is produced.

Phosphatic fertilizer. Beverly Ober and Edward H. Wight (to Oberphos Co.). U. S. 1,929,710, Oct. 10. Phosphate rock is converted to available forms by digesting it with an acid such as H<sub>2</sub>SO<sub>4</sub> under superatm. pressure, followed by agitating the digestion products with other fertilizer materials such as NaNO<sub>3</sub>, fish scrap, garbage, etc., and reducing the pressure, adding NH<sub>3</sub> and further agitating and cooling.

Mulching product in sheet form. Carrel C. Bryar. U. S. 1,931,248, Oct. 17. For making a sheet mulch, sewage sludge is filtered to produce a filter cake of org. sewage sludge residue conditioned to produce a material self-sustaining in sheet form, and the filter cake is formed into a sheet. App. is described.

Artificial fog for protecting plants from frost and parasites. Ulrich Müller. U. S. 1,930,904, Oct. 17. A fog blanket is formed over plants by the simple volatilization of fog-forming and parasite-killing material such as "chlorosulfo acid" and H<sub>2</sub>SO<sub>4</sub>. App. is described.

Insecticides. Nicholas A. Sankowsky and Stewart C. Fulton (to Standard Oil Development Co.). Brit. 394,977, July 4, 1933. Insecticidal plant exts., e. g., of pyrethrum, derris and cubé, are mixed with hydrocarbons having considerable "unsatd." content and obtained by the extn. of petroleum naphtha with a solvent, e. g., liquid SO<sub>2</sub>, having preferential solvent action on the unsatd. hydrocarbons. A hydrocarbon vehicle contg. unsatd. aromatic hydrocarbons, obtained in any manner, to the extent of above 15%, the mixt. boiling at 350-600°F., is also suitable as a solvent.

Insecticides. I. G. Farbenind. A.-G. (Kurt Meisenburg and Hans Kukenthal, inventors). Ger. 583,344, Sept. 1, 1933. Use is made of cyanohydrin esters of the formula R<sub>1</sub>(R<sub>2</sub>)C(CN)OCOR<sub>3</sub>, where R<sub>1</sub> and R<sub>2</sub> may be H or org. radicals, and R<sub>3</sub> is an org. radical. The esters may be used alone or with appropriate addns. Details are given of the prepn. and use of cyclohexanocyanohydrin acetate, b<sub>p</sub> 118°, and crotonaldehydecyanohydrin benzoate, b<sub>p</sub> 159-60°, and acetate, b<sub>p</sub> 85-7°. The benzoates of the cyanohydrins from furfural, acrolein, sorbic aldehyde, pinacolone and CH<sub>2</sub>O have also been prepd.

Non-corrosive insecticidal mixture suitable for use as an agricultural spray. Earl B. Alvord (to Grasselli Chemical Co.). U. S. 1,931,367, Oct. 17. A mixt., imparting to its aq. suspensions a pH of 4.0 and greater, comprises Ba fluosilicate as an active parasiticide ingredient together with a substantially neutral fluoride such as BaF<sub>2</sub> or Al-Na fluoride which has a water soly. greater than that of CaF<sub>2</sub>.

Insecticides, fungicides, etc. I. G. Farbenind. A.-G. (Karl Marx and Karl Brodersen, inventors). Ger. 583,020, Aug. 26, 1933. Addn. to 551,199 (C. A. 26,

4408). Use is made of the sulfonation products of mixts. of mineral oils (other than ordinary coal-tar oils) with phenols, naphthols or their derivs.

**Insecticides and fungicides.** I. G. Farbenind. A.-G. (Addolf Steindorff and Kaspar Pfaff, inventors). Ger. 583,343, Sept. 1, 1933. See Fr 746,258 (C. A. 27, 4623).

**Fumigating.** Anthony Standen, Thomas Ewan and Imperial Chemical Industries Ltd. Brit. 895,761, July 24, 1933. In rapidly generating a definite quantity of HCN a predetd. amt. of NaCN is caused to react with the equiv. amt. of NaHSO<sub>4</sub> in the presence of an amt. of H<sub>2</sub>O to give a mol. ratio, H<sub>2</sub>O:NaCN, of 10:1, an optimum yield of gas being thereby obtained in a short time.

## 16 THE FERMENTATION INDUSTRIES

C. N. FREY

**Manufacture of alcohol in Denmark.** J. Filrsten. *Chimie & industrie Special No.*, 1177-95 (June, 1933). - A description of the development of the alc.-distg. industry in Denmark and of the process and Aalborg plant of the Aktieselskabet De Danske Spritfabrikker, touching also on the agronomical problems relating to the use of the raw materials, particularly potatoes. A. P.-C.

**Utilization of marine algae for preparation of yeast and alcohol.** G. K. Burgvitz. *Bull. acad. sci. U. S. S. R., Classe sci. math. nat.* 1933, No. 6, 837-16. The fungus, *Mucor javanicus*, differing from yeasts, has the advantages: (1) that it ferments *Laminaria* ext. without preliminary hydrolysis and (2) produces larger alc. yields; its disadvantage is slowness in fermenting 9-12 days. Fermentation by yeasts proceeds only in hydrolyzed ext. and not all of the sugar ferments. Addn. of 2-5% glucose to the *Laminaria* ext. materially speeds up fermentation. *Laminaria* may also serve as a food medium for yeast cultivation. The fermentation ability of *Saccharomyces cerevisiae* is not decreased when allowed to remain on *Laminaria* ext. for 105 days. Growth of *Saccharomyces cerevisiae* on *Laminaria* ext. is inferior to its growth on malt wort. Expts. with yeasts *Torulopsis III* and *XIII* showed that on *Laminaria* ext. (concn. 1% Ball.) the yeast harvest equals that obtained on bread wort of the same concn. All yeasts were cultivated at 25° on a 5% *Laminaria saccharina* ext., 4° Ball. and  $p_{H}$  5.91 and 10% ext. of the same *Laminaria*, 7° Ball.,  $p_{H}$  5.92. W. P. Bucks.

**The mannitol fermentation of levulose.** V. Bolcato. *Ann. chim. applicata* 23, 405-10 (1933). The fermentation of levulose by means of mannitol acetic acid enzymes takes place with the production of lactic acid, mannitol, AcOH and CO<sub>2</sub>. There is no relation between the amts. of lactic acid and mannitol formed. But for every 3 mols. of levulose, there are formed 2 mols. mannitol, 2 AcOH and 2 CO<sub>2</sub>. A. W. Conteri.

**The mannitol fermentation of beet fodder.** J. Vondrák. *Chimie & industrie Special No.*, 1113-6 (June, 1933). See C. A. 27, 1981. A. Papineau-Couture.

**Report on (the analysis of) vinegar.** A. M. Hurv. *J. Assoc. Official Agr. Chem.* 16, 536-10 (1933), cf. C. A. 27, 160. - Collaborative tests confirmed that the use of NH<sub>4</sub>Ph<sub>2</sub> as inside indicator in the detn. of glycerol gives as accurate results as K<sub>2</sub>Fe(CN)<sub>6</sub> as outside indicator, but is quicker and more convenient. In the detn. of ash, the tendency to cake or form dense carbonaceous residues is effectively prevented by addn. of 2 g. sucrose. The highest ashing temp. which can be safely used without altering the ratio of H<sub>2</sub>O-insol. to H<sub>2</sub>O-sol. P<sub>2</sub>O<sub>5</sub> is 550°, while it is practically impossible to obtain proper ashing at or below 500°. A. Papineau-Couture.

**Simple test for slop vinegar in wine vinegar.** Hans Barsch. *Pharm. Zentralhalle* 74, 599-600 (1933). - Shake vigorously for 1 min. 20 cc. of the sample in a closed 50 cc. cylinder. If the product contains 5% or more vinegar from brewer's grains or slops, a thick fine-pored white foam will appear at the surface, permanent for a period of 1/2 hr. to several hrs., depending on the amt. of added slop vinegar. On similar treatment pure wine vinegar yields a coarse-grained, very loose and thin film of bubbles which rapidly disappear. The peculiar behavior of slop vinegar may be due to the presence of saponin.

**The barleys of 1933.** J. Raux. *Brasserie & malterie* 23, 214-16 (1933). A brief outline of the characteristics

(from the standpoint of malting) of 1933 barley crops of the principal districts of France. A. P.-C.

**Commercial utilization of Spartan barley.** H. C. Ruther. *Mich. Agr. Expt. Sta., Quart. Bull.* 16, 23-5 (1933). - This barley is particularly well adapted to Mich. soil and climatic conditions. It is entirely suitable for malting purposes. It is also adapted for pearling and use in soup. C. R. Fellers.

**Evaluation of malt barleys.** P. Petit. *Brasserie & malterie* 23, 193-5, 209-13 (1933). - A brief discussion of the factors which should be considered in evaluating the malting qualities of barley, with suggestions for establishing a mutually satisfactory basis of purchase; it is more particularly suggested that there should be a requirement of a min. germinative power of 90%. A. P.-C.

**Preliminary washing of hops.** P. Petit. *Brasserie & malterie* 23, 177-82 (1933). A brief discussion of the advantages of extg. hops with hot water before adding to the brewing kettle. A. Papineau-Couture.

**Czechoslovakian hop oil and its practical utilization.** Nebovidské and J. Horel. *Chimie & industrie Special No.*, 1208-13 (June, 1933). - Analyses are given of a no. of oils obtained by distg. Czechoslovakian hops of the 1930 and 1931 crops, and discussed from the standpoint of their possible utilization in the beverage, perfumery and soap industry, and ultimately also in medicine. A. P.-C.

**Better "3.2" cider.** Weaver L. Marston. *Food Ind.* 5, 358-9 (1933). Methods of fermented cider manuf. in England are outlined. The Sharples supercentrifuge for clarification has proved very satisfactory and retains both body and flavor of the beverage better than filtration methods. By centrifuging a partially fermented cider, the fermentation is greatly checked. As a rough check in detg. the alc. content of fermenting cider, a 9-point drop (0.009) in sp. gr. is equal to approx. 1% of alc. by vol. The parts of the centrifuge coming in contact with the cider should be made of Monel or other non-corrosive metal. C. R. Fellers.

**Production conditions and composition of vinasses of agricultural distilleries in Czechoslovakia.** Václav Viličkovský. *Chimie & industrie Special No.*, 1190-9 (June, 1933). The compns. of the vinasses from 36 distilleries working with potatoes, corn, and potatoes with molasses is given and discussed from the standpoint of the conditions affecting the compn. of the vinasses. A. P.-C.

**Practical application of chemistry in wine cellars.** Herzberg. *Chem.-Ztg.* 57, 681-2 (1933). The importance of the chemist is emphasized in controlling the samples and correcting various faults and diseases of wine. C. N. Frey.

**Observations on the composition of the wines of the 1932 vintage in Champagne.** Lebrun and Radet. *Ann. fals.* 26, 474-80 (1933). - Analyses of 33 wines are tabulated and briefly discussed. A. Papineau-Couture.

**The color of wine.** F. Montequi. *Anales soc. españ. fis. quim.* 31, 663-8 (1933). - The color curve of red wine was tested under various conditions and in comparison with artificial colors, for special properties of a given kind of wine, to det. the conclusions claimed regarding storage and adulteration. The Pulfrich photometer was used. The results indicate the importance this work might prove to have if carried further. E. M. Symmes.

**Sulfurous acid in wine making. III. Dissociation of combined sulfur dioxide in grape musts and wines.** L. Moreau and E. Vinet. *Ann. fals.* 26, 454-63 (1933);

cf. C. A. 22, 2485.—The free and combined  $\text{SO}_2$  in must or wine are in equilibrium; removal of part (or all) of the free  $\text{SO}_2$  (e. g., by oxidation) disturbs the equilibrium, which is reestablished by disson. of part of the combined which becomes free. Plotting the amt. of  $\text{SO}_2$  oxidized as abscissas against remaining free  $\text{SO}_2$  (after equil. has been reestablished) as ordinates gives a curve consisting of 2 straight lines, the left-hand one corresponding to disson. of the  $\text{SO}_2$  combined in virtue of the R no. (C. A. 21, 4018); the other (which makes a more acute angle with the x axis) to disson. of the  $\text{SO}_2$  combined in virtue of the T no. As the inhibition of fermentation of must by  $\text{SO}_2$  depends only on the free  $\text{SO}_2$  content, it is important to know how much of the combined  $\text{SO}_2$  will be disson. into free when the free  $\text{SO}_2$  is reduced to a given value, and M. and V. explain how this may be calcd. from the above curves. In the course of fermentation of must contg.  $\text{SO}_2$ , the whole of the  $\text{SO}_2$  becomes combined with the volatile constituents (probably paraldehyde) in the early stages of fermentation. Increase in temp. not only increases the rate of disson., but also displaces the equil. point in the direction of higher free  $\text{SO}_2$ ; increase in acidity retards or even completely inhibits disson. of the combined  $\text{SO}_2$ ; reduction of the acidity increases it, and complete neutralization causes practically complete liberation of the combined in not over 5 min.; diln. increases the disson. A. Papineau-Couture

**Trihexosan and dextrinose in the manufacture of beer.** J. Satava and P. Rach. *Chimie & Industrie Special No.*, 1173-6 (June, 1933).—Trihexosan,  $[\alpha]_D^{20}$  102.1°, reducing power equiv. to 3.1% glucose, was isolated by a tedious method combining fermentation, dialysis and repeated pptns. with alc. and requiring about 3 weeks. Trihexosan,  $[\alpha]_D^{20}$  103.3°, reducing power equiv. to 0.82, mol. wt. 487 (theoretical 486.2) was obtained from beer wort by defecating with tannic acid and basic Pb acetate, pptg. excess Pb with  $\text{H}_2\text{S}$ , neutralizing with NaOH, eliminating colloidal S with Carborafin, dialyzing to remove acetates and ash, pptg. with alc., oxidizing the ppt. with  $\text{H}_2\text{O}_2$  and NaOH and pptg. with alc. To det. trihexosan in beer, after oxidation with  $\text{H}_2\text{O}_2$  and NaOH, the liquid is hydrolyzed with HCl to convert the trihexosan quantitatively into glucose, which is detd. During the primary fermentation of beer, about 30% of the trihexosan is decompd. by the yeast. A. Papineau-Couture

**Study of the composition of pitch baths (for beer kegs).** L. Idoux. *Brasserie & malterie* 23, 182-9, 197-200 (1933).—Deterioration of the pitch used for treating beer kegs is due to loss of volatile matter and decompn. of the resin, by heat. Though Fe kettles are corroded to some extent, as shown by the presence of an appreciable amt. of Fe in the ash of used pitch, this Fe apparently does not act as an oxidation catalyst. The pitch deteriorates much more rapidly in practice than in lab. tests conducted under apparently the same conditions of heating; this is probably due to uneven heating and local superheating in com. equipment. It is suggested that Al kettles would reduce this trouble, and would probably be more economical than Fe kettles, in spite of their higher first cost.

1 Better results would probably be obtained by removing a small portion of the used pitch at the end of each day's run and replacing by fresh pitch, than by the usual practice of waiting till the bath is useless and then renewing the whole charge. A. Papineau-Couture

**Improvement of yields by the use of various types of saccharomyces.** René Pique. *Chimie & Industrie Special No.*, 1108-72 (June, 1933).—A brief discussion showing that the use of various strains of *Saccharomyces ellipsoideus*, especially studied for each must to be fermented, increases the yield of alc., accelerates the rate of fermentation, ensures preservation of the finished beverage by elimination of injurious ferments and imparts a characteristic bouquet depending on the particular strain used. A. Papineau-Couture

**The vitality of yeast plasma.** Vaclav Jonaš. *Chimie & Industrie Special No.*, 1164 7 (June, 1933).—See C. A. 25, 5011. A. Papineau-Couture

**Ultra-violet irradiation stimulates yeast activity.** Wm. L. Owen. *Food Ind.* 5, 252-4 (1933).—The fermentation of molasses wort by yeast is greatly accelerated by short exposure to ultra-violet rays, and the final efficiency of fermentation is also increased perceptibly by it. A baker's yeast, given a limited exposure to ultra-violet rays (2300-3100 Å.) has a definite acceleration and a greater sustained fermentation activity than untreated yeast of the same origin; also because of this greater sustained fermentation activity, irradiated yeast is capable of producing a greater leavening effect than untreated yeast. Thus, less yeast is required to produce normal fermentation. In general, 24% less yeast can be used with an actual saving of time. C. R. Fellers

**Kvapn. and its applications [in the distillery industry]** (Lafitte) 13. Sterilizing and purifying sugar liquids (Brit. pat. 395,527) 28.

**Distillation for purification of alcoholic liquids, etc.** Elot Ricard and Henri M. Guinot (to Soc. anon. des distilleries des Deux-Sevres). U. S. 1,929,901, Oct. 10. For purifying alc. worts contg. impurities insol. in water, the material is heated to boiling temp., fed into the middle portion of a distg. zone which is heated at its lower end, and a stream of water heated to about 98° is sprayed into the upper part of the distg. zone; vapors which reach the upper part of the distg. zone are collected, condensed to form a liquid which seps. into 2 layers, one of the layers contg. the impurities is decanted, and the other layer is returned to the distg. zone, and dil. alc. freed from impurities is collected at the base of the distg. zone. Various details of app. and operation are described.

**Evaporator suitable for concentrating distillery slop, etc.** Gustave T. Reich. U. S. 1,930,861, Oct. 17.

**Yeast.** Hans Braasch and Arnold Braasch. Brit. 395,910, July 20, 1933. See Fr. 748,594 (C. A. 27, 5471).

**Yeast.** "Salvis" A.-G. für Nahrungsmittel- und chem. Ind. (Rudolf Bertel, inventor). Ger. 582,090, Aug. 10, 1933. See Fr. 716,250 (C. A. 26, 2375).

## 17--PHARMACEUTICAL CHEMISTRY

W O EMBERY

**Brazilian vegetable drugs. I. Vegetable mercury Apodanthera smilacifolia.** O. de Lazzarini Peckolt. *Rev. brasil med. pharm.* 9, 93-101 (1933).—The leaves and roots of this tree contain an alkaloid, apodantherine 0.053 g. % in the leaves; 0.112 g. % in the roots) and a glucoside, apodanthine (0.046 g. % in the leaves; 0.024 g. % in the roots). The roots and leaves are used in the treatment of syphilis and rheumatism. E. S. G. B.

**Standardization of hormone preparations.** H. Harms. *Egyptian Med. Assoc.* 16, 874-96 (1933).—Review.

**Cosmetic colors.** E. G. McDonough. *Drug and Cosmetic Ind.* 33, 333-4 (1933).—A discussion. H. M. B.

**Volatile oil of Juniperus polycarpus.** Kock. H. N. Rutovskii, K. Guseva and L. Kuroleva. *Reichstoff Ind. u. Kosmetik* 8, 161-2 (1933).—Three samples of leaf oil showed the following consts.:  $d_4^{20}$  0.8685-0.8746,  $[\alpha]_D^{20}$  +22.2° to +25.82°,  $n_D^{20}$  1.4745-1.4758, acid no. 1.50-2.03, ester no. 0-26.84. The oils when rectified by steam distn. had the consts.:  $d_4^{20}$  0.8598,  $[\alpha]_D^{20}$  +27.08°,  $n_D^{20}$  1.4710. Oil was distd. in vacuo into 8 fractions and the first 4 fractions were redistd. over Na at ordinary pressures into fractions I-VI with b. p. ranging from 151° to 167°. (11) yielded  $\alpha$ -pinene (nitroschloride m. 95-6°, benzylnitrolamine m. 122°) and a pinonic acid which yielded a cryst. acid m. 69-70°,  $[\alpha]_D^{20}$  +71.17° in alc. soln. (semicarbazone

m. 147°); camphene is present in (III); in (VI) and (VII) were found cedrol, m. 85.5° (phenylurethan m. 107°) (5-20%) and a small quantity of a liquid primary or secondary sesquiterpene alc. and cedrene (about 5%) or a similar sesquiterpene.  $\alpha$ -Pinene and camphene constituted about 55% of the oil. H. M. Burlage

**Glycerol.** K. Pfaff. *Richtstoff Ind. u. Kosmetik* 8, 164 (1933).—The value of glycerol in cosmetics and cosmetic preps. (with formulas) is discussed.

H. M. Burlage

**Essential oil of Podocarpus totara.** Geo. B. Beath. *J. Soc. Chem. Ind.* 52, 538 40T (1933).—The pale green oil obtained by steam distn. of the leaves contained 8% alc. (calcd. as  $C_{15}H_{24}O$ ), very little acid and ketone, and practically no ester. Vacuum distn. gave 43-52% of a terpene fraction and 19.28% of a sesquiterpene fraction in which were identified  $\alpha$ - and  $\beta$ -pinene and cadinene, resp. The latter fraction contained no monodendrene or eudesmene, since only cadalene was obtained on dehydrogenation. The distn. residue consisted of a diterpene,  $[\alpha]_D^{25} +44.7^\circ$  (in  $CHCl_3$ ), m. 55°, shown to be identical with immene (I) obtained by Finlay and McDowell (*C. A.* 19, 1176) from Rinnu (*Dacrydium cupressinum*). Refluxing with 90%  $HCOOH$  gave an isomer, m. 107°, identified with isodacrene, obtained by isomerization of dacrene, from *Dacrydium biforme* (*C. A.* 24, 2739). I gave a monohydrochloride m. 63°, a mononitroschloride m. 86.8°, a tetrabromide m. 55-60°, dihydromimene (II), and (very slowly) tetrahydromimene. I is therefore tricyclic, with one C-C group probably tetrasubstituted. Ozonolysis of I gave  $CH_2O$  equiv. to one  $CH_2$  group. This is the first double bond hydrogenated, since II gave no  $CH_2O$ . Formulas for I and for isoretene obtained from it by dehydrogenation with S are discussed. A. M. C.

**Sterilization of iodoform.** Ph. A. Coppens. *Pharm. Weekblad* 70, 1053-7 (1933).  $CHI_3$  may be kept sterile by covering it with a shallow layer of 96% EtOH.

A. W. Dox

**Communications from the laboratory of the Dutch society for the advancement of pharmacy. No. 35 Glandulae thyreoidae.** H. J. van Giffen. *Pharm. Weekblad* 70, 1101-14 (1933). A detailed discussion of the Dutch Pharm. and the Hunter-Reith methods for detn. of I in thyroid preps. and a report on the I content of 25 comm. preps. as detd. by the 2 methods. The latter method gave higher I values for all samples examd.

A. W. Dox

**Manufacture of medicaments in the druggist's laboratory.** R. A. Feldhoff. *Apoth. Ztg.* 48, 1205-8 (1933).—It is shown how the manuf. of preps. like aqua amygdalarum amararum, Bi subnitrate, Bi subgallate, Bi subsalicylate, reduced Fe with sugar,  $NH_4$ , Na and K iodides may be conveniently and practically effected in the av. druggist's lab.

W. O. Emery

**Germany's import of drugs, and domestic drug and condiment plant culture.** Ilse Esdorn. *Apoth. Ztg.* 48, *Deut. Apotheker* 2, 211 16 (1933).—Both export and import data are tabulated for the years 1913, '30, '31 and '32.

W. O. E.

**Bark of Ailanthus glandulosa Desf., and its bitter principle ailanthin.** R. Wasicky and S. Gerin. *Pharm. Presse, Wiss. prakt. Mitt.* 1933, 120 3. The anatomical structure of the bark of *Ailanthus glandulosa* in the various stages of development has been investigated. From this bark a new substance, *ailanthin*, was isolated. It has the compn.  $C_{20}H_{26}O_{10}$ , m. 223.4°, very bitter in taste, difficultly sol. in cold, somewhat more in hot,  $H_2O$ , more readily in  $H_2O/H$ , very sol. in  $CHCl_3$ , insol. in petr. ether. It crystallizes from  $CHCl_3$  in tetrahedrons, and in many ways resembles other bitter principles like quassin occurring in the Simarubaceae. *Ailanthin* tastes distinctly bitter in a diln. of 1:5,000,000. The trunk bark contains a fluorescing, hydrolyzable substance, probably a glucoside of hydroxycommarin, and also a saponin. W. O. E.

**Chemical constitution and importance of certain photographic developers, as related more particularly to prescription druggists.** Fritz Hagelstein. *Pharm. Zentralhalle* 74, 409-15, 426 30, 454 60 (1933). W. O. E.

**Sterilization of sodium bicarbonate solution.** Ar. Mihalovici. *Pharm. Zentralhalle* 74, 615 (1933); cf. *C. A.* 27, 3032.—Reference is made to recent papers on this subject. An app. ("Tinner Siphon") is described for effecting the desired sterilization. W. O. E.

**Prehistoric representatives of official plants.** Robert Potonié. *Pharm. Ztg.* 78, 1040-2 (1933).—Certain paleobotanic illustrations of leaves are shown in connection with their pharmacognostic relationships. W. O. E.

**Investigations on galenical preparations. I. L. Rosenthaler.** *Pharm. Ztg.* 78, 1000-4 (1933).—The results involve 3 galenicals: aqua amygdalarum amararum, aqua laurocerasi and aqua aurantii florum, official in the D. A.-B. 6, and hence are mainly important in view of its requirements. W. O. E.

**Analytical practice in the apothecary and commercial laboratories.** W. Peyer. *Sudderl. Apoth. Ztg.* 73, 414 16, 421 3, 463 5, 469 70, 476-7, 503-4, 517-18, 523-4, 548 9 (1933); cf. *C. A.* 27, 4347.—Several analytical schemes are systematically arranged for the examn. of crude drugs, their exts. and galenicals. W. O. E.

**Estimation of mustard oil in semen sinapis via the D. A.-B. 6.** Hans Kaiser and Otto Leeb. *Sudderl. Apoth. Ztg.* 73, 612-13 (1933).—An exptl. study of the official method leads to certain suggestions for its improvement. W. O. E.

**Latest investigations of digitalis glucosides.** Hans Kaiser. *Sudderl. Apoth. Ztg.* 73, 627 9 (1933).—An address. W. O. E.

**Recent regulations governing drug announcements in Bavaria and Württemberg.** Georg Herold. *Sudderl. Apoth. Ztg.* 73, 641-4 (1933). W. O. E.

**The bactericidal efficiency of menthol and camphor.** Louis Gershenfeld and Ruth E. Miller. *Am. J. Pharm.* 105, 490 502 (1933).—Results obtained from tests of menthol and camphor solus. in solvents of liquid petrolatum, in water, and in a solvent composed of alc., glycerol, water and soap are summarized as follows: (1) Solns. of 1% menthol, 1% camphor, and a mixt. of 1% menthol and 1% camphor in liquid petrolatum did not display any bactericidal action in any of the tests performed. (2) Satd. aq. solns. of menthol proved bactericidal against *B. typhosus* within 30 min. (with 0.1 cc. of culture), and bactericidal against *Staphylococcus aureus* (0.1 cc. of culture) within 24 hrs. in most instances (bacteriostatic in only one instance); while bacteriostatic action was displayed against *B. coli*. Satd. aq. camphor solus. displayed bacteriostatic action only against *B. coli* and neither bactericidal nor bacteriostatic action against *B. typhosus* or *Staphylococcus aureus*. (3) Phenol coeffs. for menthol and for camphor in a solvent composed of 31 parts each of alc., glycerol and water and 6.6 parts of soap when tested by the phenol coeff. test against *B. typhosus* and *Staphylococcus aureus* are listed. The effect of temp. on the bactericidal efficiency of these menthol and camphor solus. is shown in tables, but as the phenol controls also vary with the temp., in some instances this increase in bactericidal efficiency of menthol and camphor is not indicated by its phenol coeff. at the higher temp. unless the computation is made against the phenol at its standard temp. A bibliography is appended. W. G. Gaessler

**The production of pseudomorphine from morphine.** Charles C. Fulton. *Am. J. Pharm.* 105, 503-30 (1933).—Pseudomorphine can be manufd. from morphine in alk. soln. with a yield of about 90% by oxidation with ferricyanide, or by heating with a salt of Hg as  $HgCl_2$ . It can also be manufd. by catalytic oxidation with a yield of about 75%, with persulfate as oxidizing agent, Cu as catalyst, and pyridine as the substance with which Cu forms an effective complex. This new catalytic method and the Hg method originated with F. The production of pseudomorphine can be made a characteristic and fairly simple test for morphine either by utilizing the green color it gives with  $HCHO$ ,  $H_2SO_4$  and an oxidizing agent, or by recognizing its crystals under the microscope. In the color test the morphine is converted by simple oxidation, in the crystal test by catalytic oxidation. These new

tests for morphine are sensitive to a 1:3000 morphine soln.

W. G. Gaessler

**Sketch of the properties of pseudomorphine.** Charles C. Fulton. *Am. J. Pharm.* 105, 511-13 (1933).

W. G. Gaessler

• **Essential oil of Chrysanthemum lavandulaefolium Makino var. typicum Makino.** I. Buyu (Takeyu) Takahashi. *J. Chem. Soc. Japan* 54, 843-51 (1933).—Steamy distn. and ether extn. of the distillate gives an oil having a greenish color and agreeable aroma, yield 0.8%. It is slightly acid, but an alc. soln. of this oil has no reaction with  $\text{FeCl}_3$ . Consts. are:  $d_{20}^{25}$  0.9283,  $n_D^{25}$  1.4622,  $[\alpha]_D^{25}$  +8.68°, acid no. 6.0, sapon. no. 36.5, sapon no. after acetylation 177.5. The oil has a characteristic aroma and  $b_{10}$  75.6°; its semicarbazone,  $\text{C}_{10}\text{H}_{15}\text{ON}_3$ , m. 185-6°, *p*-nitrophenylhydrazine,  $\text{C}_{10}\text{H}_{13}(\text{O})\text{N}_2$ , m. 131-5°, 2,4-dinitrophenylhydrazine,  $\text{C}_{10}\text{H}_{12}(\text{O})\text{N}_2$ , m. 115-6°; it is a new ketone and is named *chrysantone*,  $\text{C}_{10}\text{H}_{16}\text{O}$ . The other constituents of the oil are an alc.  $\text{C}_{10}\text{H}_{18}\text{O}$ ,  $b_{10}$  92-4°,  $d_{20}^{25}$  0.951,  $n_D^{25}$  1.4761,  $[\alpha]_D^{25}$  +3.28, M. R. 44.53, and azulene,  $b_{10}$  145-50°,  $d_{20}^{25}$  0.9273,  $n_D^{25}$  1.4990. K. Kitsuta

**The volatile oil from the fruit of "Sankan."** Keigai Sebe. *J. Chem. Soc. Japan* 54, 973-81 (1933).—The skin of the ripe fruit (a variety of *Citrus tokotan* Hayata) has a light yellow color with a lemon-odor-like oil. Consts. are:  $d_{20}^{25}$  0.8460,  $n_D^{25}$  1.4719,  $[\alpha]_D^{25}$  +92.4°,  $[\alpha]_D^{25}$  108.96°, acid value 0.00, ester value 6.25 (after acetylation 12.70). Over 95% of the oil is *d*-limonene (I). The principal aroma of the oil is due to the presence of aldehydes (mostly octyl- and some decylaldehyde), alcs. (mostly  $\alpha$ -terpineol and a diol-*fin* alc.  $\text{C}_{11}\text{H}_{20}\text{O}$  (II)) and Ac ester of II. Terpenes other than I are pinene,  $\alpha$ -terpinene and *p*-phellandrene. The basic substance contained in the oil is the Me ester of methylanthranic acid. K. Kitsuta

**Depilatories.** Alejandro Berenguer Luque. *Quim. ind.* 10, 173-8 (1933). Alkali or alk. earth sulfides are the basic constituents of chem. depilatories. Theoretical generalities on these sulfides and their hydrolysis are presented, even acid sulfides are shown to have an alk. reaction. The industrial prepn. of these chem. depilatories is described with suggestions for diminishing their caustic action on the skin. M. McMahon

**Importance of medicinal plants in the chemical and pharmaceutical industry** K. Muller. *Chimie et industrie Special No.*, 1014-16 (June, 1933).—A brief discussion A. Papineau-Couture

**Preparation and purification of ergot alkaloids.** Miloš Hrold. *Chimie et industrie Special No.*, 1017-18 (June, 1933). A very brief review of the extn. and properties of ergot alkaloids. The following method has been developed for the com. extn. of ergot alkaloids: ground, slightly moistened and alkalinized ergot is extd. with  $\text{C}_6\text{H}_6$ ,  $\text{H}_2\text{O}$ -sol. impurities and coloring matter are extd. by shaking with very dil. alkali, the alkaloids are extd. by shaking with  $\text{H}_2\text{O}$  slightly acidulated with tartaric or citric acid, pptd. by adding  $\text{Na}_2\text{CO}_3$  to a *pH* of not over 7.7, filtered under suction, dissolved in  $\text{Et}_2\text{O}$  (to remove any histamine that may be present), extd. with 1% sulfanilic acid soln. and pptd. with  $\text{Na}_2\text{CO}_3$ ; the ppt., consisting of ergotamine, ergotamine and ergotamine, but contg. no ergotamine, is dried *in vacuo* in a current of dry, inert gas. A. P.-C.

**Report on rhubarb and rhaponticum.** Arno Viehoever. *Assoc. Official Agr. Chem.* 16, 527-31 (1933). A brief review of morphological, histological, chem., physico-chem. and physiol. methods applicable to the differentiation between these 2 drugs. A. Papineau-Couture

**Solubilities of some organic drugs and their application in drug analysis** L. R. Warren. *J. Assoc. Official Agr. Chem.* 16, 571-5 (1933).—The solubilities of 32 org. drugs in  $\text{C}_6\text{H}_6$ ,  $\text{CCl}_4$  and petroleum benzine, as found in the literature or detd. in W.'s lab., are tabulated and discussed from the standpoint of their applicability to the analytical sepn. of the drugs. A. Papineau-Couture

**Three periods of British pharmacy.** Ernest C. Cripps. *Chemist and Druggist* 119, 224-8 (1933).—An illustrated and documented account is given of the development of Allen and Hanbury's Ltd., since 1715. Pharmacy in the

Napoleonic era. *Ibid.* 348-52.—Reprints of historical documents are shown and discussed. S. Waldbott

**The Canadian Formulary.** Anon. *Chemist and Druggist* 119, 372-3 (1933).—A review of the 5th revision of the Canadian Addendum to the Brit. Pharm. S. W.

**Physicochemical characters of oil of the yolk of eggs, in particular its solubility in ethyl alcohol.** Gaetano Vita and Lorenzo Bracaloni. *J. pharm. chim.* 18, 104-8 (1933).—In the prepn. of egg ext. for serum therapy,  $\text{EtOH}$  is used as the extg. solvent. As the presence of small quantities of the yellow oil of eggs causes opalescence in the serum, the soly. curves of egg oil in alc. at concns. of 60-90% by vol. and at temps. of -4°, 15° and 37° were detd. to find the conditions of min. soly. of the oil in alc. The tabulated results and graph show that for alc. concns. of 90-90% the influence of temp. on soly. is very great; for concns. between 90 and 60% it is almost nil. The consts. of pure oil of egg are:  $d_{20}^{25}$  0.918; m. p. 16-18°; f. p. 16-17°; fatty acids m. p. 36-38°; s. p. 33-35°; thermosulfuric degree (Fortelli) 67°;  $n_D^{25}$  (Zeiss) 60.2; sapon. no. 199.5-200.5; I no. 69.8-70.3. Differences in the consts. obtained by different authors are caused by variety of feed; they also depend on the method of extn. and subsequent purification. S. Waldbott

**Assay of preparations of nux vomica.** E. Léger. *J. pharm. chim.* 18, 281-7 (1933).—The assay method is based on that for cinchona in the French Codex 1908. The use of  $\text{CHCl}_3\text{-Et}_2\text{O}$  (1:3) or of  $\text{C}_6\text{H}_6$  for extg. the alkaloids from nux vomica is advised, both giving nearly identical results. S. Waldbott

**The hydrates of sodium *p*-aminobenzenearsonate.** Ernest Kahane. *J. pharm. chim.* 18, 334-9 (1933).—When this compd. is exposed to the air at about 20°, it rapidly acquires either by hydration or by dehydration a  $\text{H}_2\text{O}$  content of 18.43%, indicating a trihydrate. When this is kept in an atm. satd. with  $\text{H}_2\text{O}$  vapor, it rapidly becomes a pentahydrate tending to a hexahydrate. The anhyd. salt when warmed to 42° in air, is changed to a monohydrate; this is also formed at ordinary temp. (20°) when the trihydrate loses  $\text{H}_2\text{O}$  *in vacuo* over concd.  $\text{H}_2\text{SO}_4$ . Seven references are added. S. Waldbott

**Preparation of glutathione.** Mlle. M. Th. Regnier. *J. pharm. chim.* 18, 369-76 (1933).—Ext. glutathione (A) from fresh or vacuum-dried baker's yeast with 45% alc.; this effects complete extn. and avoids sticky, unfilterable solns. Ppt. A from this soln. as Pb salt, decompn. with  $\text{H}_2\text{SO}_4$  gives impure A. Ppt. A as a Cu salt (cf. Hopkins, *C. A.* 15, 3119), a soln. of pure A is obtained by decompn. with  $\text{H}_2\text{S}$ , evapn. *in vacuo* below 30° and pptn. by abs. alc. as a white microcryst. powder. Its formula is that of a tripeptide; yield 1 g. + from 1 kg. fresh yeast. Ten references. S. Waldbott

**Pseudo iodine indexes of essential oils.** R. Huerre. *J. pharm. chim.* 18, 381-4 (1933); cf. Morvillez and Tackx, *C. A.* 26, 3874.—These indexes, referred to 100 g. of essence, are the max. quantities of I which disappear under definite exptl. conditions when the essence is in contact with an alc. soln. of I contg. the optimum excess of I. Dissolve 0.2 g. essence in 20 cc  $\text{CHCl}_3$ , add 30 cc. of 10% alc. soln. of I (i. e., about 15% wt. of essence). Allow this and a blank without the essence to stand for 2 hrs. in a shaded place, add to each 20 cc. 10% soln. of KI and titrate first with a *N* and then end with a 0.1 *N*  $\text{Na}_2\text{S}_2\text{O}_3$  soln. The wt. of I disappeared  $\times$  500 gives the pseudo I index. In 15 constituents of essences, the values obtained were 0-300; in 37 essences 0-330.2. S. W.

**The chemical composition of liquor arsenicalis Fowleri** Axel Jerinstad and Ottar Ostby. *Pharm. Acta Helv.* 8, 144-6 (1933).—By heating 1 g.  $\text{As}_2\text{O}_3$  in aq. soln. with  $\text{K}_2\text{CO}_3$ , 0.1134 g.  $\text{CO}_2$  was given off. This clearly points to the formation of the compd.  $\text{KH}(\text{AsO}_2)_2$ . S. W.

**Adulteration of drugs and their microscopic study in filtered ultra-violet light.** R. Freudweiler. *Pharm. Acta Helv.* 8, 147-51, 155-61, 190-201 (1933); cf. Wasicky, *C. A.* 8, 203; Miglet and Bischoff, *C. A.* 24, 4900, and following abstr.—Powd. drugs of analogous character can be differentiated by ultra-violet light. Among the groups studied were strophanthus seeds, anise, caraway, conium

and similar seeds, saffron and possible adulterants, pepper and other spices, roots and rhizomes (belladonna, veratrum, hellebore), ginger and similar drugs, leaves and herbs (belladonna, digitalis, artemisia), and the chamomile group. S. Waldbott

**Fluorescence-microscopic studies. I. Crocus (saffron) and some of its adulterants.** Kurt Leupin. *Pharm. Acta Helv.* 8, 166-70 (1933).—The percentage limits at which adulterants may still be detected are given for calendula and carthamus flowers, turmeric root, santal wood, capsicum, corn starch, cane sugar and meat fibers, examd. in powder form or in liquid media:  $H_2O$ , glycerol, alc. or chloral hydrate. S. Waldbott

**Newer ointment bases of Pharm. Helv. V; direction for the preparation of cetyl alcohol.** J. B. Lang. *Pharm. Acta Helv.* 8, 165-6 (1933).—*Unguentum ceticum* ( $C_{18}H_{38}O$ ), adeps laevis 10, white vaselin 86) can take up more than its own wt. of  $H_2O$ ; besides, it can never turn rancid. To prep. cetyl alc., m. 48-8.2°, cetaceum is saponified with alc. KOH, the K palmitate is converted into (EtO-insol.) Ca soap, and the cetyl alc. is extd. with  $H_2O$ . L. obtained a sapon. no. 10-15; the demand of the Pharm. for a sapon. no. = 0 is too rigorous. S. Waldbott

**The pharmacy of the future. II.** E. Armstrong. *Pharm. J.* 131, 432-5 (1933).—An address, with photograph of the author; also cf. *Chemist and Druggist* 119, 455-6 (1933). S. Waldbott

**Agar-agar and paraffin emulsions; extemporaneous preparation.** C. L. M. Brown and E. A. Lami. *Pharm. J.* 131, 341 (1933). To obtain the best results, triturate  $NaHCO_3$  10 grams, powd. tragacanth 20 and powd. acacia 60 grains to a smooth paste with glycerol 6 drachms. Dissolve agar 17.5 grains in boiling water 2 fluid oz., add this while hot to the mixt. in the mortar while stirring. Then add liquid paraffin 3 oz., 2-3 drachms at a time. Triturate until cold, allow to stand for 1 hr., triturate again for 5 min. and add water to complete 6 oz. If an emulsifying app. worked by hand is available (cf. *Thi* 315), a thick emulsion is obtained with agar 15,  $NaHCO_3$  6 grams, liquid paraffin 3 oz., tragacanth 5, acacia 5 grains, glycerol 2 drachms, water to make 6 oz. S. Waldbott

**A hospital pharmacopeia of 1814.** R. J. Stratton. *Pharm. J.* 131, 347 (1933). The contents of a small manuscript formulary used by the Ipswich Public Dispensary, entitled *Pharmacopoeia Valetudinariae Hippocrenensis*, probably by John Morgan, apothecary and house surgeon, are described. S. Waldbott

**The rate of solution of tablets; a method for its determination.** G. H. Elliott. *Pharm. J.* 131, 511 (1933). The "solvoimeter" of Colman (*C. A.* 26, 878) was used. It is based on the increase of buoyancy of the app. in water as the tablet is going into soln. Graphs are given showing the soly. in eg. per min. of 5 kinds of tablets:  $KI$ ,  $NH_4Br$ , quinine  $2HCl$ , hexamine and phenazone. The influence of temp. was also detd. S. Waldbott

**Edible yeasts (Givartovskii) 12.** Constitution of jasmine (Treff, Werner) 10. Manuf. of absorbent cotton (Fehre) 25. Citral (Bogett, Fourman) 10. Stenderoff polarimeter (Seiler) 1. Czechoslovakian hop oil and its utilization [in perfumes and medicine] (Nebovidský, Horcl) 16. White mineral medicinal oil (U. S. pat. 1,928,832) 22. Substituted fatty acid amides [use in medicines and cosm. ties] (Ger. pat. 582,390) 30. 3,5-Diiodo-4-pyridone (Brit. pat. 391, 37) 10

**Therapeutic preparation.** Fritz Lange and Kug. Fehre. Ger. 584,014, Sept. 13, 1933. A prepn. for distending the blood vessels and reducing the blood pressure is prepd. as follows. Animal organs contg. blood vessels are extd. with water and the ext. is freed from albumin in known manner. Phosphatides are then extd. with an org. solvent, e. g., petroleum ether, the purified aq. ext. is evapd., and the residue is extd. with a higher alc., e. g.,  $PrOH$  or  $BuOH$ . The ext. is evapd. and the evapn. residue is extd. with  $EtOH$  satd. with  $HCl$ . This ext.

is evapd., the evapn. residue is dissolved in water and the desired product finally recovered as a cryst. salt (picrate, flavianate or aurate).

**Therapeutic adsorbent preparations.** Pharmaceutische Werke "Norgine" A.-G. Ger. 583,141 Aug. 29, 1933. See Austrian 130,242 (*C. A.* 27, 1091).

**Hydroxyamino acids and their derivatives.** Schering-Kahlbaum A.-G. (Otto v. Schickl, inventor). Ger. 583,243, Aug. 31, 1933. Glycidic acid and its alkyl, aryl or aralkyl substitution products, or their esters or amides, are heated with primary or secondary monoamines. Water-sol. hydroxyamino acids (or derivs. thereof) of therapeutic value are obtained. Thus, dimethylglycidic Et ester and  $PhNH_2$ , heated for 5 hrs. in xylene under reflux, yield  $\alpha$ -hydroxy- $\beta$ -aminoisovaleric Et ester, m. 70-1°; the corresponding amide, m. 102°, and  $\beta$ -methylamino compd., b<sub>p</sub> 172-4°, are prepd. similarly from dimethylglycidic amide (I) and  $PhNHMe$ , resp. The following have also been obtained:  $\alpha$ -hydroxy- $\beta$ -phenetidinisovaleric amide, m. 105°;  $\alpha$ -hydroxy- $\beta$ -aminopyridinoisovaleric amide, m. 182-3°;  $\alpha$ -hydroxy- $\beta$ -(6-methoxy-8-amino)quinolinisovaleric diethylamide, b<sub>p</sub> 225-8° ( $HCl$  salt, m. (decompu.) 170-1°);  $\alpha$ -hydroxy- $\alpha$ -methyl- $\beta$ -phenyl- $\beta$ -methylaminopropionic methylamide, m. 98° ( $HCl$  salt, m. 245°); a compd. m. 151°, from I and 1-phenyl-2,3-dimethyl-4-amino-5-pyrazolone; and a compd. unmelted at 250°, from I and Na arsanilate.

**Pyridine derivatives.** Schering-Kahlbaum A.-G. Brit. 395,119, July 13, 1933. See Ger. 583,132 (*C. A.* 27, 1093).

**Theophylline derivative.** Chem.-Pharm. A.-G. Bad Homburg (Erwin Kohlstaedt, inventor). Ger. 583,054, Aug. 28, 1933. A water-sol. compd. of therapeutic value is prepd. by treating theophylline with 2 mols. of diethanolamine. Examples are given.

**Urea and thiourea derivatives.** I. G. Farbenind. A.-G. (Fritz Schouhofer and Hans Heneka, inventors). Ger. 583,207, Aug. 30, 1933. Urea and thiourea derivs., which contain the residue of a heterocyclic or aromatic heterocyclic compd. contg. a quaternary N atom in the nucleus, are prepd. by standard processes. In typical examples, (1) 6-aminoquinoline is treated with  $COCl_2$  and the resulting urea (di- $HCl$  salt m. 260-2°) is converted into quaternary salts m., resp., 235-7°, 260°, 255-7°, and 168°, with 2 mols. of  $Me_2SO_4$ ,  $MeCl$ ,  $MeI$  and 1 mol. of  $Me_2SO_4$ , 5- and 7-aminoquinoline and 3-aminoquinoline similarly yield ureas m., resp., 284-5°, 282° and 276°, which form with  $Me_2SO_4$  salts m., resp., 217°, 228°, and 193°; (2) quinoline-6-carboxylic acid (I), boiled in benzene soln. with 6-methoxy-8-aminoquinoline, yields N (quinolyl-6)-N'-(6-methoxyquinolyl-8)urea m. 239°, which forms with 1 mol. of  $Me_2SO_4$  a salt m. 239°; asym. ureas are obtainable similarly from I and 1-phenyl-2,3-dimethyl-4-amino-5-pyrazolone (urea m. 242-3°, urea di- $Me_2SO_4$  salt m. 217°), N-methyl-1,2,3,4-tetrahydro-6-aminoquinoline (urea m. 227°, urea di- $Me_2SO_4$  salt m. 206-7°), 6-(3'-amino-4'-toluyl)aminoquinoline (urea m. 245°, urea di- $Me_2SO_4$  salt m. 224°), 3-diethylaminoethoxyaniline (urea m. 193°, urea di- $Me_2SO_4$  salt described), 6-p-aminophenoxyquinoline (urea m. 209°, urea di- $Me_2SO_4$  salt m. 242°), (methyl)(diethylaminoethyl)amine (di- $Me_2SO_4$  salt of the urea is described), 4-amino-3',5'-dimethyldiphenyl ether (urea m. 198°, urea  $Me_2SO_4$  salt m. 234°), 5-aminoisouquinoline (di- $Me_2SO_4$  salt of the urea m. 221-2°), 7-aminoquinoline (urea m. 229°, urea- $Me_2SO_4$  salt m. 238°), and 5-chloro-8-aminoisouquinoline (urea m. 234°, urea  $Me_2SO_4$  salt m. 227°); 2 mols. of I and 1 mol. of 1,2,3,4-tetrahydro-6-aminoquinoline yield N-(quinolyl-6)-N'-(1-(quinolyl-6-carbamino)-1,2,3,4-tetrahydroquinolyl-6)urea m. 160°, the di- $Me_2SO_4$  salt of which m. 187°. The following have also been obtained: N,N'-di(5-nitroquinolyl-6)urea di- $MeCl$ , m. 242°; N,N'-di(6-methoxyquinolyl-5)urea  $Me_2SO_4$  salt m. 192°; N,N'-di(8-methoxyquinolyl-6)urea  $Me_2SO_4$  salt m. 194°; the  $Me_2SO_4$  salt m. 211°, of the urea m. 276-7°, from 3-aminocarbolidine; the di- $MeCl$  salt m. 100-5°, and  $Me_2SO_4$  salt of N,N'-di(8-methylquinolyl-6)-thiourea m. 196°; the di- $MeCl$  salts m., resp., 237°, 150°.

and 205-6°, of the sym. thioureas m., resp., 190°, 178°, and 208°, from 6- and 8-aminoquinoline and 3-aminoquinoline; a  $\text{Me}_2\text{SO}_4$  salt, decomp. 180°, of the thiourea m. 179-80° from 7-aminoquinoline; *N*-(quinolyl-6)-(thiourea m. 218°, and its salts, m., resp., 208-9° and 234°, with  $\text{Me}_2\text{SO}_4$  and  $\text{MeCl}$ ; *N*-(quinolyl-6)urea  $\text{MeCl}$  salt m. 240°; *N,N'*-di- $\gamma$ -pyridylurea m. 208°, and  $\text{Me}_2\text{SO}_4$  salt m. 191°; a nitro-*N,N'*-di- $\gamma$ -pyridylurea di- $\text{MeCl}$  salt; *N*-(quinolyl-7)-*N'*-(1-*p*-ethoxyphenylbenzimidazolyl-5)-urea m. 248°, (di- $\text{Me}_2\text{SO}_4$  salt m. 241°); *N*-(quinolyl-6)-*N'*-piperidylurea m. 166°, (mono- $\text{Me}_2\text{SO}_4$  salt m. 181°); *N*-(quinolyl-6)-*N'*-(3-nitro-4-tolyl)urea m. 250-2°, (mono- $\text{Me}_2\text{SO}_4$  salt m. 226°); a salt m. 268-70°, of *N*-(quinolyl-6)-*N'*-(3-amino-4-tolyl)urea with 1 mol. each of  $\text{Me}_2\text{SO}_4$  and  $\text{HCl}$ ; *N*-(quinolyl-6)-*N'*-(4-dimethylaminophenyl)urea m. 220°, and its di- $\text{MeCl}$  salt m. 190°; a sulfate m. 150-2°, of 6-guanylcarbaminoquinoline methyl chloride; 6-quinolinecarbonyl-6'-quinolylsemicarbazide, m. 230°, and its di- $\text{MeCl}$  salt m. 252°. The salts are effective against blood parasites.

F. H. O.

**Cyanamide-formaldehyde condensation product.** I. G. Farbenind. A.-G. (Hans Schmidt, inventor). Ger. 580,830, July 17, 1933. Addn. to 522,056 (C. A. 25, 3130-1).  $\text{CN}_2\text{H}_2$  is treated at atm. temp. with  $\text{CH}_2\text{O}$  in aq. acid soln., and the mixt. is then warmed. A condensation product not identical with that described in Ger. 522,056 is obtained. The product is useful as an intermediate for drugs. The use of impure  $\text{CN}_2\text{H}_2$  prep'd directly from  $\text{CaCN}_2$  is excluded. Examples are given.

**Stable acridine salt solutions.** I. G. Farbenind. A.-G. Brit. 395,405, July 17, 1933. Addn. to 342,690 (C. A. 25, 4663). Aq. solns. for injection purposes are manifd. by incorporating a reducing substance, other than a carbohydrate, with a (soln. of a) salt of an aminoacridine or aminoacridinium comp'd, other than the salts of 3,6-diaminoacridine or 3,6-diamino-10-alkylacridinium comp'd, or double compds. thereof. Suitable acridine compds. are the salts of substitution products of 3,6-diaminoacridine and 3,6-diamino-10-alkylacridinium compds. and of other aminoacridines or aminoacridinium compds. or their substitution products or the corresponding double compds. The salts of  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SO}_4$  or sulfoxylic acid, as such or in the form of derivs., e. g., compds. with aldehydes or ketones, and hydrazines and hydroxylamines, or mixts. thereof, may be used as reducing substances. Other compds. advantageous for therapeutic application, e. g., glucose, adrenaline, acid amides, glycerol, pyridine, methylene blue,  $\text{CaCl}_2$  or  $\text{Ag}$  salts, may be added. Examples describe the prepn. of solns. contg. (1) 2,7-dimethyl-3,6-diamino-10-methylacridinium chloride, 2,7-dimethyl-3,6-diaminoacridine- $\text{HCl}$ ,  $\text{NaHSO}_4$  and  $\text{Na}_2\text{SO}_4$ ; (2) 2,7-dimethyl-3-amino-6-dimethylamino-10-methylacridinium chloride, acetone bisulfite,  $\text{Na}_2\text{SO}_4$  and glucose or an acid amide, etc.

**Chondroitin compounds.** Arthur E. Meyer (to Chappel Bros., Inc.). U. S. 1,929,786, Oct. 10. Cartilage is treated with a water-sol. aldehyde such as formaldehyde to insolubilize protein matter assoc'd. with the cartilage and the latter is then ext'd. with an alk. soln. such as  $\text{NaOH}$  to obtain desired chondroitin compds. which are purified and sepd. and may be used for medicinal purposes.

**Organic metallic compounds.** I. G. Farbenind. A.-G. Heinrich Jung and Hans Andersag, inventors). Ger. 580,516, July 12, 1933. Addn. to 578,488 (C. A. 27, 149-50). Complex metal compds. are prep'd. by various standard methods from 1,2,3-triazole derivs. which are substituted by or condensed with an aromatic or heterocyclic ring contg. an acid or basic salt-forming group. Examples are given of the prepn. of Au compds. of Na benzotriazole-*p*-carboxylate (I), Na benzotriazole-*p*-arsonate, Na benzotriazole-*p*-sulfonate, and Na benzotriazole-*p*-phosphate (II); Cu compds. of I, II, benzotriazole-*p*-carboxylic acid (III) and III diethylaminoethyl ester, and Hg and Ag compds. of III. The products are generally sol. in water and are of therapeutic value.

**Double calcium salts of organic acids.** Chemische Fabrik vormals Sandoz. Brit. 394,596, June 29, 1933.

1 See Fr. 747,350 (C. A. 27, 4886). The salts possess therapeutic properties.

**Double calcium salts.** Chemische Fabrik vormals Sandoz. Brit. 395,296, July 13, 1933. Double  $\text{Ca}_2$  salts that are useful therapeutically are prep'd. by treatment of  $\text{CaBr}_2$  with equimol. proportions of the  $\text{Ca}$  salts of polyhydroxymonocarboxylic acids derived from polyaldoses. In a modification polyaldoses are oxidized with  $\text{Ca}$  hypobromite in presence of  $\text{Ca}(\text{OH})_2$ , the  $\text{CaBr}_2$  liberated uniting with the neutralized oxidation product. Among examples (1)  $\text{CaBr}_2$  is ground, or dissolved in hot  $\text{H}_2\text{O}$ , with  $\text{Ca}$  lactobionate, the double salt being crystd. from the soln., and (2) lactose is oxidized in aq. soln. as described above.

**Acetamides.** Karl Ziegler. Brit. 394,084, June 22, 1933. Tertiary acetamides contg. 2 or 3 unsatd. alkyl groups are prep'd. by sapon. the corresponding nitriles which may be prep'd. by the process of Brit. 393,955 (C. A. 27, 5755). The products possess hypnotic properties. Examples are given of the sapon. with  $\text{KOH}$  of triallylacetoneitrile, diallylethylacetoneitrile and diallylpropylacetoneitrile dissolved in  $\text{BuOH}$ .

**Hormones.** Schering-Kahlbaum A.-G. (Erwin Schwenk and Friedrich Hildebrandt, inventors). Ger. 584,211, Sept. 16, 1933. Crude compus. contg. sexual hormones are treated with a reagent which forms a condensation product with the hormones and also contains a salt-forming group, or a group convertible into a salt-forming group. The salt-forming portion of the mixt. is then sepd. and the hormone concentrate recovered by standard methods. Thus, a crude male sexual hormone prep'n may be fused with phthalic anhydride and the acid phthalic ester of the hormone extd. with dil. soda soln. and then sapond. Similarly, the ovarian hormone of the formula  $\text{C}_{27}\text{H}_{48}\text{O}_2$ , which contains a  $\text{CO}$  group, may be treated with phenylhydrazinesulfonic acid. Details are given.

**Hormones.** Schering-Kahlbaum A.-G. (Max Gehrke, inventor). Ger. 584,340, Sept. 18, 1933. Sexual hormones are recovered by extg. urine in the warm with a normally solid hydrocarbon. The latter is sepd. after the mixt. has been cooled, and the hormone is then concd. by distg. the hydrocarbon or by crystg. it from an org. solvent.

**Hormone derivatives.** Schering-Kahlbaum A.-G. (Friedrich Hildebrandt and Erwin Schwenk, inventors). Ger. 581,113, Sept. 15, 1933. Cryst. esters of ovarian hormones are prep'd. directly from crude oil contg. such hormones by treating the oil with aq. alkali, sepg. the aq. layer, and treating this with an acclating agent. Examples are given.

**Foam-producing compositions.** August Karreth. Ger. 583,388, Sept. 2, 1933. Compns. which are stable at atm. temp. but evolve foam at a raised temp., e. g., at body temp., without addn. of water or other liquid, are prep'd. by uniting two or more gelatinous compns., each of which contains one component of a gas-evolving reaction, and one at least of which contains water or other liquid. Thus, granules of an aq. gelatin compn. contg.  $\text{NaHCO}_3$  may be embedded in an aq. gelatin compn. contg. tartaric acid. Numerous details and modifications are described. The products may be used, *inter alia*, for medical and cosmetic purposes.

**Medicines for animals.** Josef Pekar. Brit. 395,264, July 13, 1933. Medicines for injection for the treatment of septic ailments are prep'd. by dissolving oil of parsley in abs. alc. and then diluting with an amt. of distd.  $\text{H}_2\text{O}$  varying according to the nature of the disease and the animal.

**Elastic impression material suitable for making casts of parts of the human body, etc.** Carl R. Kellner. U. S. 1,930,391, Oct. 10. A nitrogenous colloid such as agar-agar and gelatin is used together with soap, Na borate and resin combined in soln.

**Synthetic perfumes.** Soc. anon. M. Naef & Cie. Brit. 394,197, June 22, 1933. See Fr. 744,345 (C. A. 27, 4031).

**Perfumes.** Compagnie de Béthune. Ger. 580,450,

July 11, 1933. See Fr. 728,998 (C. A. 26, 8071) and 42, 143 (C. A. 27, 4881).

**Disinfectants.** I. G. Farbeniud. A.-G. Brit. 394,026, June 22, 1933. Bis(haloxyphenyl) oxides and substitution products thereof are obtained by halogenating the bis(hydroxyphenyl)oxides by customary methods with the introduction of 1 or more halogen atoms or by replacing active groups in the compds., e. g., NH<sub>2</sub> groups, by halogen in known manner. The OH groups may be protected by alkylation, followed later by hydrolysis. Among examples bis(2-hydroxyphenyl)oxide is brominated and chlorinated in AcOH or iodinated in NH<sub>4</sub> soln. to give mono- or di-halo derivs. and bis(2-methoxyphenyl) oxide is nitrated and brominated followed by hydrolysis of the MeO group.

**Water-soluble disinfectants.** Paul Godrich (to Godrich Chemical Co.). U. S. 1,930,474, Oct. 17. Fatty oils such as olive oil or castor oil and bactericidal aromatic compds. such as chlorothymol which are sol. in the fatty oils but insol. or slightly sol. in water are dissolved together and concd. H<sub>2</sub>SO<sub>4</sub> is added to the oil soln. at a reduced temp. (suitably about 20°) and the action of the acid is permitted to continue until the solvent oil has become substantially sulfonated. Excess acid is then removed by washing.

**Denicotinizing tobacco.** Ludwig Lippmann. Brit.

395,458, July 20, 1933. Denicotinizing is effected by moistening the leaves with pure H<sub>2</sub>O, slightly alk. H<sub>2</sub>O or a virulent alk. liquor contg. tobacco bacteria, permitting free or copious access of air during fermentation and removing the excess of alk. produced by adding an org. acid. A cloth soaked in AcOH may be laid over the leaves or the acid may be applied by sprinkling. Volatile aromatic bases removed by the air current are collected and returned to the leaves. Cf. C. A. 27, 376.

**Denicotinizing tobacco.** Alfred Schuchard and Willy Stelkuns. Brit. 394,889, July 6, 1933. A substance for use in smoking tobacco to remove nicotine and other toxic vapors is composed of (1) Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> or other substance which, on heating, will liberate a substance, e. g., SO<sub>2</sub>, that combines with nicotine, (2) a binding material and (3) an oxidizing agent which prevents, e. g., the formation of SO<sub>2</sub> from SO<sub>3</sub>. The binding material may be formed by dissolving 20 parts ethylcellulose in 80 parts CCl<sub>4</sub>. To this may be added the other ingredients, KNO<sub>3</sub> serving as oxidizing agent. Nitrocellulose may serve both as binder and oxidizing agent. Thin rods of the dried compressed compn. are inserted in cigar, cigaret or pipe.

**Apparatus for conditioning tobacco by subjecting it to dry or moist air in counter- or co-current in a rotating drum having baffle members.** Eduard Quester. Brit. 395,818, July 27, 1933.

## 18 ACIDS, ALKALIES, SALTS AND SUNDRIES

### B. M. SUMMIS

**Experiments in construction and use of apparatus from acid-resisting concrete for production of phosphoric acid.** B. Krapukhin and N. Zuev. *Khimstron* 5, 2455 60 (1933). A mixt. of andesite, Na SiF<sub>6</sub> and water glass was used in insulating a H<sub>3</sub>PO<sub>4</sub> absorption tower and a Cottrell precipitator, with tolerably good results. C. Blane

**Sulfuric acid produced from heavy refinery sludge by use of improved contact process.** S. F. Spangler. *Oil Gas J.* 32, No. 23, 76, 78 (1933). The sludge is burned in a rotary kiln countercurrent to combustion gases from a furnace. The gases are cooled, washed with H<sub>2</sub>O and sepd. from condensed oil. The gases are further oxidized in a secondary furnace and pass into a catalytic converter, which converts 98% of the SO<sub>2</sub> to SO<sub>3</sub>. This is absorbed to make any strength acid desired. A recovery of approx. 90% of the acid content of the sludge may be expected. J. R. Strong

**Intensification of the tower process for sulfuric acid.** V. N. Shul'z. *J. Chem. Ind. (Moscow)* 1933, No. 6, 17-31; cf. C. A. 26, 4684. Theoretical and practical methods of improving the yield are given. H. M. L.

**The manufacture of sulfate of alumina.** R. L. Brown. *J. Southeastern Sect. Am. Water Works Assoc.* 3, 87-91 (1933). W. A. Moore

**Photoelectric study of the sedimentation of fresh, exhausted and regenerated activated charcoals.** V. D. Netuka. *Chimie et Industrie Special No.* 1160 3 (June, 1933). The rate of sedimentation of fresh, exhausted and thermally regenerated carboraffin and norites in pure water and in 0.02 N KCl and Na<sub>2</sub>SO<sub>4</sub> was studied by means of the Sander photoelectric colorimeter (C. A. 23, 3122-3). Fresh norite settles more rapidly than fresh carboraffin; electrolytes do not affect the rate of sedimentation of norite but merely considerably that of carboraffin. Neither of the charcoals settles in pure water when exhausted; electrolytes increase their rate of sedimentation, that of norite more than that of carboraffin. The sedimentation of thermally regenerated norite is slightly lower than that of fresh norite, and is but little affected by electrolytes. The sedimentation of thermally regenerated carboraffin is slightly quicker than that of the fresh product and is accelerated by electrolytes. A. Papineau-Couture

**Carbon black.** G. R. Hopkins and H. Backus. *Bur. Mines, Minerals Yearbook* 1932-33, 546-54 (1933). Alden H. Emery

**The manufacture of bromine in France.** M. Kaltenbach. *Mém. compt. rend. soc. ing. civils France* 85, 418 15 (1932). A detailed description of the process used for the manuf. of Br in France and Tunis (started in 1916), with particular emphasis on recent improvements in mfg. equipment. A. Papineau-Couture

**Helium.** Andrew Stewart. *Bur. Mines, Information Circ.* 6745, 46 pp. (1933). — The discovery of He and other rare inert gases, their properties, sources, com. production, and uses are described. Ninety references. A. H. E.

**Sulfur in Chile.** S. V. Griffith. *Mining Mag.* 49, 137-44, 213 19 (1933). Occurrence, mining and prepn. are described, with details of production, costs, etc., for the year 1931, at 3 individual plants. At Mount Ollague the retort system of refining has been abandoned in favor of one employing steam at 60 lb. per sq. in., and patented. A. W. Furbank

**Lime.** Paul Hatmcker and A. T. Coons. *Bur. Mines, Minerals Yearbook* 1932-33, 629 37 (1933). **Sulfur and pyrites.** R. H. Ridgway and A. W. Mitchell. *Ibid.* 669 86. **Salt, bromine, calcium chloride, and iodine.** A. T. Coons. *Ibid.* 687 700. **Barite and barium products.** R. M. Santmyers and B. H. Stoddard. *Ibid.* 753 61.

**Potash.** J. H. Hedges. *Ibid.* 763 75. **Natural sodium compounds and boron minerals.** A. T. Coons. *Ibid.* 795 8. Alden H. Emery

**Fluorspar and cryolite.** H. W. Davis. *Bur. Mines, Minerals Yearbook* 1932-33, 723 34. **Feldspar.** H. O. Rogers and C. Galilee. *Ibid.* 735 43 (1933). A. H. E.

**The possibility and importance of organization of the production of silica gel in the Soviet Union.** S. T. Sanovich. *J. Chem. Ind. (Moscow)* 1933, No. 6, 677 81. The methods of manuf. of SiO<sub>2</sub> gel are reviewed. H. M. Leicester

**Experiments on the continuous preparation of superphosphates by the method of prolonged mixing.** B. A. Sokolovskii and E. N. Zhuchkov. *J. Chem. Ind. (Moscow)* 1933, No. 6, 62 70. — Phosphorite is well mixed with 10% excess H<sub>2</sub>SO<sub>4</sub> for 40-60 min., and the mixt. allowed to stand for 1/2-1 hr. after leaving the mixer. About 93-7% decompn. occurs, and a superphosphate of good phys. properties is obtained. About 31% of the P in the phosphorite is recovered. H. M. Leicester

**Experiments on the preparation of double and enriched superphosphates from Khibin apatite.** L. Berlin and V. Mikerov. *J. Chem. Ind. (Moscow)* 1933, No. 6, 55-62.

Superphosphates may be prepd. from apatite by its extrn. with the theoretical amt. of  $H_2SO_4$  plus 10% more of 40%  $H_2PO_4$ . Impurities in the apatite decrease the amt. of  $P_2O_5$  in the product. The purer the apatite, the greater is the improvement of the resulting superphosphate when it is allowed to stand. H. M. Leicester

Fuller's earth. W. W. Adams and C. Galiner. Bur. Mines, *Minerals Yearbook* 1932-33, 709-14 (1933).

Comparison of methanol and other anti-freeze agents. T. C. Albin. *Chem. & Met. Eng.* 40, 526-7 (1933).

E. H.

Hydrocyanic acid. Konrad Keller (to Ges. für Kohlen-technik m. b. H.). U. S. 1,931,441, Oct. 17. A soln. of  $NH_4CNS$  is treated with  $HNO_3$  which is always maintained in excess of 1% in the reaction mixt.

Concentrating nitric acid. Emil Lüscher (to Lonza Elektrizitätswerke und chemische Fabriken A.-G.). U. S. 1,930,881, Oct. 17. Finely divided O (suitably after passing through ceramic plates or the like) is forced into a mixt. of dil.  $HNO_3$  and  $NO_2$  at an elevated temp. and under a pressure of at least 15 atm.

Means for feeding nitric acid to Glover towers. Georg Schaich. Ger. 583,051, Aug. 28, 1933.

Phosphoric acid. Charles H. Milligan (to American Agricultural Chemical Co.). U. S. 1,929,441, Oct. 10. A phosphate-contg. material such as animal bone matter or a mineral phosphate is treated with  $H_2SO_4$  in a quantity sufficient to form  $H_2PO_4$ . The admixed materials are then contacted with not exceeding 5 multiples by wt. of an extrn. liquid consisting mainly of  $BuOH$ ; the soln. thus formed is sepd. from undissolved material and the  $H_2PO_4$  is recovered from it. U. S. 1,929,442 relates to an otherwise generally similar process in which the  $H_2PO_4$  is extrd. from the reaction mixt. by a "water-immiscible oxygenated hydrocarbon liquid of not exceeding 8 C atoms in the chain carrying the O group," such as Bu, Am, heptyl and hexyl alks., etc. and U. S. 1,929,443 relates to a like process in which the  $H_2PO_4$  thus std. is converted into an alkali metal phosphate, as by reaction with  $Na_2CO_3$ .

Phosphoric acid, dicalcium phosphate, fertilizers. Oskar Smeltwerk A S and Erling Johnson. Ger. 579,627 & 9, June 30, 1933, 579,731, July 3, 1933, and 580,521, July 12, 1933. Addns. to 573,284 (C. A. 27, 3042). The mother liquor contg.  $H_2PO_4$  obtained from crude phosphate and  $HNO_3$  as described in Ger. 573,284, is worked up to mixed fertilizers by treatment with substances such as urea or cyanamide, with or without salts of K or  $NH_4$  (579,627). Alternatively, the mother liquor may be treated with  $NH_4$ ,  $(NH_4)_2CO_3$ , or an alkali carbonate in an amt. sufficient to ppt. Ca as  $CaHPO_4$ , the filtrate from the sepn. of  $CaHPO_4$  being evapd. to produce mixed fertilizer (579,628). When  $H_2PO_4$  or phosphate is to be recovered from the mother liquor, the latter may be freed from  $HNO_3$  by distn., preferably *in vacuo* at a low temp., at any stage in the process (579,629). Foam in the treatment of the crude phosphate with  $HNO_3$  is avoided by adding the acid in two stages. The first addn. should be sufficient to react with gas-evolving impurities and give a pasty product, which should be thoroughly kneaded before the rest of the acid is added (579,630).  $CaHPO_4$  obtained as described in Ger. 579,628, may be mixed with crude phosphate and the mixt. treated with  $HNO_3$  as described in Ger. 573,284.  $Ca(NO_3)_2 \cdot 4H_2O$  is extrd. from the soln., and the mother liquor is treated as described in Ger. 579,628 (580,521). Each patent includes examples and numerous details. Cf. C. A. 27, 1461.

Water-supply system for sulfuric acid chambers. Georg Schaich. Ger. 583,050, Aug. 28, 1933.

Catalytic combustion of ammonia. Ivar W. Cederberg. Brit. 394,400, June 29, 1933. In the catalytic combustion of  $NH_3$  the gas mixt. is passed through the catalyst with a linear flow velocity which exceeds the linear velocity of combustion under the conditions existing in the catalyst. The velocity may be higher in the free gas space before the catalyst than through the catalyst proper. A suitable

catalyst consists of (twilled) galloon fabric of Pt-Rh alloy; cooling, e. g., by a liquid layer of  $H_2O$  or  $HNO_3$ , may be applied if necessary. App. is described.

Alkali metal aluminates. Robert O. Wood (to National Aniline & Chemical Co.). U. S. 1,929,619, Oct. 10. For the production of alkali metal aluminate and of a product contg. an activated Fe oxide, a mixt. comprising an alumina sludge, an Fe oxide sludge and an alkali such as  $Na_2CO_3$  is calcined at 650-900°, the calcined material is treated with water, and the soln. of alkali aluminate thus formed is sepd. from the insol. residual material comprising activated Fe oxide.

Pure alkali metal and ammonium orthophosphates. Charles F. Booth (to Swann Research, Inc.). U. S. 1,929,476, Oct. 10. Assocd. impurities present in solns. of mono-basic orthophosphates are treated (as by the addn. of  $MnO_2$  or  $KMnO_4$ ) to form in them a trivalent Mn compd. and effect pptn. of impurities.

Alkali phosphates. Chemische Fabrik Budenheim A.-G. Ger. 583,052, Aug. 28, 1933. See Fr. 741,347 (C. A. 27, 4035).

Alkali phosphates. Metallges. A.-G. (Conway von Girschwald, Hans Weilmann and Gerhardt Roesner, inventors). Ger. 584,348, Sept. 18, 1933. See U. S. 1,903,582 (C. A. 27, 3297).

Alkali silicates or alkali-alkaline earth silicates. Henkel & Cie. G. m. b. H. Brit. 395,182, July 13, 1933. Alkali-alk. earth silicates are manufd. by treating alkali chlorides,  $SiO_2$  and alk. earth compds., heated electrically to a high temp., with steam, the heat being generated in the interior of the furnace by using the furnace contents as the heating resistance. App. is described.

Carbides; phosphorus. Nikolaem Caro and Albert R. Frank (H. Heinrich Franck and Hans Fuldner, inventors). Ger. 583,454, Sept. 4, 1933. Crude  $Ca_3(PO_4)_2$  or other tertiary phosphate is heated with C to 1200-1600° or more, if necessary under a raised partial pressure of CO. Under these conditions, P is driven off from the mixt., but the formation of carbide is precluded. When all the P has been driven off, the residue is heated to a higher temp. under a CO partial pressure of 1 atm. to cause the formation of carbide.

Chlorides and oxalates of thorium and the rare earth metals. I. G. Farbenind. A.-G. Brit. 395,300, July 13, 1933. Hydrated chlorides of the Ce group, free from Th, are pptd. by passing HCl into a soln. of said chlorides, contg. also  $ThCl_4$ , cooled to about 0° or below, or by the addn. of chlorides, e. g., of Ca or Mg, (with or without HCl) that are more sol. than Ce chloride and not pptd. by HCl at room temp. In the latter method it is unnecessary to cool the soln. The pptd. chlorides are washed with cooled coned. HCl. In an application of the process a reaction melt obtained by decomp. monazite sand in any manner is dissolved in HCl, the major part of the chlorides of the Ce group pptd. as above and the filtrate treated to ppt. the metals of the  $\gamma$  group, the remainder of the Ce group and the Th as oxalates, from which the Th is sepd. in known manner.

Cyanamides of alkaline earth metals and magnesium. Herbert Wittek. Ger. 583,476, Sept. 4, 1933. A mixt. of  $NH_3$  and  $CO_2$  is led over a dehydrating catalyst and then at 500-800° over an oxide of an alk. earth metal or Mg, or a compd. which yields such oxide. The catalyst may be  $Al_2O_3$  or a rare earth oxide, and is preferably supported on wood charcoal. The alk. earth or Mg compd. may also be mixed with a catalyst, e. g., an alkali or alk. earth halide or an alkali carbonate, or layers of the catalyst may alternate with layers of the compd. to be treated. The  $NH_3$ - $CO_2$  mixt. may contain hydrocarbons. Cf. C. A. 27, 3565.

Stabilization of phosphates. N. V. Maatschappij tot Exploitatie van de Parker Octrooien "Parker Rust Proof." Ger. 583,024, Aug. 26, 1933. Powd. phosphates are stabilized and prevented from caking by addn. of 1-5% of  $H_2BO_3$  or a similar proportion of  $ZnCO_3$ , sugar or like substance. The treatment is intended particularly for powd. phosphates required for making baths for protecting iron against rust.

**Acid metal phosphates.** Robert L. Sebastian (to American Agricultural Chemical Corp.). U. S. 1,929,452, Oct. 10. Inorg. phosphate-contg. material is treated with  $H_2SO_4$  to form  $H_2PO_4$  and the  $H_2PO_4$  formed is extd. from the reaction mixt. by an extn. liquid consisting mainly of one or more water-immiscible aliphatic alcs. contg. not more than 8 C atoms and the soln. thus formed is sepd. and treated with a metal phosphate of greater basicity than a mono-basic phosphate, such as a tri-basic phosphate in order to form an acid metal phosphate such as a di-basic phosphate.

**Aluminum oxide gel.** Earle H. Barclay (to Silica Gel Corp.). U. S. 1,929,942, Oct. 10. A soln. of an Al salt such as  $Al_2(SO_4)_3$  is mixed with a suitable reacting compd. of opposite character such as NaOH to form a gelatinous mass at low temp. under slightly alk. conditions. An Al oxide gel may be obtained which is hard, stable, highly porous and capable of absorbing water vapor to an extent of at least 21% at 25° C. when in equil. with water vapor at a temp. of 30° and a partial pressure of 22 mm. Hg.

**Ammonium nitrate and sulfate.** De Directie van de Staatsminen in Limburg. Brit. 394,447, June 29, 1933. See Fr. 732,903 (C. A. 27, 379).

**Calcium nitrate; diammonium phosphate.** Friedrich Uhde. Ger. 584,375, Sept. 19, 1933. Crude  $Ca_3(PO_4)_2$  contg.  $CaCO_3$  is sludged with  $Ca(NO_3)_2$  soln. and treated gradually with sufficient  $HNO_3$  to react with the  $CaCO_3$  without decomp. a substantial proportion of the phosphate. Alternatively, the crude phosphate may be treated directly with a soln. of  $Ca(NO_3)_2$  contg.  $HNO_3$ , which soln. may be prepd. from nitrous gases. In either case, the soln. of  $Ca(NO_3)_2$  is sepd. and crystd., and the  $Ca_3(PO_4)_2$  then converted into  $(NH_4)_2HPO_4$  in known manner.

**Dicalcium phosphate and ammonium chloride.** Louis Durepaire and Bernard Quanquin. U. S. 1,930,744, Oct. 17. Natural tri-Ca phosphate is treated with HCl in the presence of a concd. soln. of  $CaCl_2$  obtained from the mother liquors of a preceding operation. Milk of lime is added to the mixt. Di-Ca phosphate is sepd. as the principal product, the remaining soln. of concd.  $CaCl_2$  is recovered, part of this  $CaCl_2$  is decompd. by reaction with  $NH_3$  and  $CO_2$  and  $NH_4Cl$  and  $CaCO_3$  are thus formed and are recovered as secondary products, and the rest of the  $CaCl_2$  liquor is recycled in the process. An arrangement of app. is described.

**Nickel and iron carbonyls.** I. G. Farbenind. A.-G. Brit. 394,906, July 9, 1933.  $Ni(CO)_4$  is obtained by acting directly with CO (contg. gases, e. g., producer, water or illuminating gas) at elevated temp. and preferably elevated pressure on Ni-contg. mats or stones or like products obtained by a melting operation and which contain Ni and S with or without other metals such as noble metals or heavy base metals that combine with S, e. g., Fe, Cu, Co, Mo. The gases may be led in a cycle, impurities such as COS being removed and CO being regenerated therefrom. The initial materials may be treated to enlarge their surface before the reaction, e. g., given a blistered or loamy structure, granulated by pouring the molten material into  $H_2O$ , etc. If Fe is present the reaction may be so conducted that Ni only is attacked or mxts. of carbonyls may be obtained which may be subsequently sepd. Impure Ni may be refined by fusing with NiS or FeS or with other sulfides or S and subjecting the resulting mat to CO action. Cf. C. A. 27, 2257.

**Phosphorus pentachloride.** I. G. Farbenind. A.-G. (Friedrich A. Henglein and Friedrich W. Stauff, inventors). Ger. 583,395, Sept. 2, 1933. The inconveniences arising from the treatment of powd.  $PCl_5$  with water are avoided by compressing the  $PCl_5$  to form cylinders or the like which sink in water.

**Silica.** Peter Spence & Sons Ltd. Ger. 584,371, Sept. 19, 1933. See Brit. 357,993 (C. A. 26, 4922).

**Silver thiosulfate.** James J. Bajda. U. S. 1,929,466, Oct. 10. Reaction is effected between a suitable Ag salt such as  $AgCl$  and an alkali thiosulfate such as that of Na in a molten state.

**Sodium aluminate.** Harold W. Heiser (to Aluminum

Co. of America). U. S. 1,930,271, Oct. 10. A mixt. of finely ground alumina and soda ash with Na aluminatate is moistened with water, formed into briquets and the latter are heated to 900–1100°.

**Sodium aluminate.** Leslie M. Clark and Henry M. Spittle (to Imperial Chemical Industries, Ltd.). U. S. 1,931,374, Oct. 17. For prep. a cryst. Na aluminate, an aq. soln. of Na aluminatate of a compn. within the range of 1.5–2.5  $Na_2O$  to 1  $Al_2O_3$  of a concn. over 45% calcd. as  $Na_2O + Al_2O_3$  is cooled and the crystals which form are sepd. from the mother liquor.

**Apparatus for making sterile solutions of sodium chloride, mercuric chloride, and other corrosive reagents.** F. & M. Lautenschläger G. m. b. H. Ger. 584,160, Sept. 15, 1933.

**Trisodium phosphate.** Nils C. Lindberg (to Victor Chemical Works). U. S. 1,930,205, Oct. 10. For eliminating chlorides and sulfates from the continuous production of  $Na_3PO_4$  from comminuted ferro-P and  $Na_2CO_3$  contg. chlorides and sulfates, the initial materials are heated together to a reaction temp. below the fusion point and sulfates and chlorides are removed by passing a blast of heated gases (such as combustion gases from petroleum hydrocarbons) over the reaction mixt. The gases are removed and the sulfates and chlorides are sepd. from them by centrifugal action to recover not more than 95% of the solids and the centrifugized solids are returned to the reaction mixt. while removing the sulfates and chlorides in the gases;  $Na_3PO_4$  is leached from the reacted mixt. with an alkali leaching liquid and  $Na_3PO_4$  is crystd. from the soln.

**Purifying "technical" crystalline sodium pyrosilicate hydrates.** Myron C. Waddell (to Grasselli Chemical Co.). U. S. 1,931,364, Oct. 17. Free caustic alkali present in the material as an impurity is converted into Na pyrosilicate hydrate (suitably by adding a Na silicate of higher  $SiO_2$  content). Cf. C. A. 27, 5158.

**Titanium dioxide.** Hermann Haber and Paul Kubelka (to Krebs Pigment and Color Corp.). U. S. 1,931,380, Oct. 17. Vaporized  $TiCl_4$  is caused to react with steam at 300–400°. U. S. 1,931,381 relates to a process in which vaporized  $TiCl_4$  is heated in the presence of free O-contg. gas such as air to about 1000° or higher.

**Treating zinc oxide residues.** Robert V. Brown and Robert O. Wood (to National Aniline & Chemical Co.). U. S. 1,931,220, Oct. 17. Zinc oxide residues such as are obtained in the reduction of org. nitro compds. are freed from org. matter (as by adding  $H_2SO_4$  and formaldehyde) and filtering, in treating a residue obtained in the production of hydrazobenzene from  $PhNO_2$ .

**Apparatus for the production of bleaching powder by intimately mixing finely divided lime with chlorine and air.** Paolo Pestalozza. Brit. 394,373, June 19, 1933.

**Borax from Searles Lake brine.** Homer L. Robson (to Burnham Chemical Co.). U. S. 1,929,902, Oct. 10. Trona is removed from the brine and its alk. is thereby increased. Pptn. of  $Na_2CO_3$  is prevented by dilg. the brine with water, and the excess alk. of the brine is reduced sufficiently to ppt. borax but not sufficiently to ppt. trona by use of  $SO_2$  and borax is pptd. by cooling the treated brine.

**System for regenerating carbonate solutions used for removing carbon dioxide from gases.** Braunkohlengas G. m. b. H. Ger. 584,449, Sept. 20, 1933.

**Hydrogen peroxide.** Kali-Chemie A.-G. Fr. 750,592, Aug. 12, 1933.  $H_2O_2$  and sol. salts of Ba are made by treating  $BaHPO_4$  (obtained by decomposing  $BaO_3$  with  $H_2PO_4$ ) with volatile acids capable of forming sol. Ba salts.

**Nitrogen-hydrogen mixtures.** Walter Klempt. U. S. 1,931,442, Oct. 17. In producing N-H mixts. by first splitting hydrocarbons with steam and air in the presence of catalysts, then converting the CO of the resulting gas mixt. to  $CO_2$  by steam in the presence of a catalyst, and finally absorbing the  $CO_2$ , the N-H production is effected in 2 stages the first of which constitutes the endothermic part of the process and consists in converting only a part

of the hydrocarbon with the aid of steam chiefly into CO and the second of which constitutes the exothermic part of the process with addn. of air by which the remaining hydrocarbon material is also chiefly converted to CO.

**Sulfur trioxide manufacture by the contact process.** Theodore V. Fowler, Jr. (to General Chemical Co.). U. S. 1,930,125, Oct. 10. A  $\text{SO}_2$  gas, having a temp. above converting temp. and of a purity such that it may be passed directly to the catalyst without poisoning the latter, is cooled to a temp. below the requisite temp. for conversion but above about  $175^\circ$  (with conservation of the heat abstracted from the gas) and the cooled gas is subsequently reheated to conversion temp., contacted with a catalyst to form  $\text{SO}_3$ , and the heat generated in the conversion reaction is utilized for the reheating of the gas supplied to the reaction. App. is described. Cf. C. A. 27, 5488.

**Apparatus for making active carbon.** Deutsche Gold- und Silber-Scheideanstalt vorm. Roeseler. Ger. 583,206, Aug. 30, 1933. Addn. to 568,400 (C. A. 27, 2019).

**Furnace for making active carbon.** Soc. de recherches et d'exploitations petrolifères. Ger. 583,184, Aug. 30, 1933. See Brit. 316,870 (C. A. 24, 1040).

**Carbon black, etc., from hydrocarbon gases and vapors.** Wm. D. Wilcox. U. S. 1,929,604, Oct. 10. For obtaining carbon black and a mixt. of H and N in controlled proportions, a partial disocn. of hydrocarbon gases such as  $\text{CH}_4$  is effected by passing them through the interior of a conduit heated to progressively higher temps. by the contact of combustion gases flowing countercurrent in contact with the exterior of the conduit; entrained carbon is removed and steam is added to the gas and it is passed through an externally heated conduit and heated to above  $700^\circ$ . Simultaneously air is passed through an externally heated conduit and heated to above  $700^\circ$  and the gas is mixed with a controlled proportion of the heated air and the resulting gases are discharged in contact with and in countercurrent flow with the exterior surfaces of the conduits through which the gas and air were introduced. App. and various operative details are described. U. S. 1,929,605 relates to app. for disocg. hydrocarbon gases and vapors in which catalytic material such as Fe or Ni may be used.

**Reactivating adsorbent carbon.** Carbo-Norit-Union Verwaltungs-G. m. b. H. Ger. 583,240, Aug. 31, 1933. The carbon is preheated to about  $200^\circ$ , e. g., with superheated steam, and then treated with a mixt. of steam and air contg. not more than 15% of O while the temp. is maintained at 300–500°. The carbon is treated in bulk, preferably in the adsorber.

**Chlorine.** Ludwig Rosenstein (to Shell Development Co.). U. S. 1,930,664, Oct. 17. See Can. 335,978 (C. A. 27, 5906).

**Drying wet chlorine.** Coke S. Lykes (to Solvay Process Co.). U. S. 1,930,526, Oct. 17. Wet Cl gas is brought into direct contact with cooling water substantially free from materials foreign to the Cl gas and the treated gas is then contacted with  $\text{H}_2\text{SO}_4$ .

**Sulfur.** Christian J. Hansen. Brit. 394,917, July 6, 1933. S is pptd. from  $\text{H}_2\text{S}$ -contg. gases by their passage through an aq. soln. of a thiocyanate, the soln. or the gas contg.  $\text{SO}_2$ .  $\text{NH}_3$  in the gases to be treated is previously removed.

**Sulfur.** Chem. Pat. in Billwärd, vorm. Hell & Sthamer A.-G. (Hanno Geller, inventor). Ger. 584,042, Sept. 14, 1933. A soln. of  $(\text{NH}_4)_2\text{S}_x$  is treated in the cold with an aldehyde, e. g.,  $\text{CH}_3\text{CHO}$ , preferably in the presence of a protective colloid, e. g., dextrin. The mixt. is stirred until pptn. occurs, and is then evapd., *in vacuo* if desired, to a paste or to dryness. The product contains up to 60% of free colloidal S, together with org. compds. of unknown constitution. It yields stable dispersions, and is useful in the agricultural, pharmaceutical and rubber industries.

**Sulfur recovery from sulfide materials such as sulfide iron ores.** Stanley I. Levy and Wm. S. Millar (to Sulphide Corp. of N. Y.). U. S. 1,929,502, Oct. 10. Sul-

fidic material contg. Fe is treated with a chlorinating medium such as Cl gas to form  $\text{FeCl}_2$  and displace the S content of the material in elemental form, in a described app. in which the sulfidic material and the chlorinating medium are subjected to the same progressive heat treatment, as by travel through a furnace in the same direction.

**Recovery of thallium from cadmium solutions.** American Smelting and Refining Co. Brit. 395,159, July 13, 1933. See U. S. 1,860,214 (C. A. 26, 5392).

**Catalytic agents.** The Goodyear Tire & Rubber Co. Brit. 394,576, June 29, 1933. Catalysts are prepd. by levigating a carrier in the presence of a salt of Ni, Co or Cu, adding a carbonate to ppt. the metal and subsequently reducing the pptd. carbonate *in situ* on the carrier. In an example 100 parts kieselguhr is levigated in a ball mill with a soln. of 100 parts Ni nitrate in 100 parts  $\text{H}_2\text{O}$ , the resulting paste being heated to  $70-80^\circ$ , and 60 parts  $\text{Na}_2\text{CO}_3$  in 260 parts  $\text{H}_2\text{O}$  is added. The mass is filtered, dried and reduced in H, C or MeOH or EtOH vapor at about  $450^\circ$ .

**Artificial masses.** Rohm & Haas A.-G. Brit. 395,291, July 13, 1933. Artificial masses are manufd. by treating polymers of acrylic acid, its derivs. or homologs, or mixts. thereof, obtained by combination of completed polymers or by combined polymerization, with Cl, with or without the application of heat and (or) pressure and with or without stirring or agitation. The products may be used for the production of lacquers, films, intermediate layers for safety glass, articles for electro-technology, threads, artificial leather, oilcloth, rayon, fabrics, sacks, elastic and transparent bandages, handles for knives, umbrellas or brushes, buttons, buckles, billiard balls, drinking cups, gramophone records, dentures, shoe soles, floor coverings, etc. Examples describe the action of Cl on (1) polymerized Me acrylate in  $\text{CHCl}_3$  soln. in the presence of light, (2) polyacrylic acid in aq. soln., (3) a film of polymerized Me acrylate, etc. A lacquer is prepd. by dissolving the product of (1) together with polymerized Bu acrylate in EtOAc with the addn. of Ti white.

**Condensation products.** N. V. de Bataafsche Petroleum Maatschappij. Brit. 395,193, July 13, 1933. Substituted carboxylic acids or carbonyl compds. are manufd. by condensing aliphatic mono-olefins, or tech. mixts. contg. aliphatic with or without aromatic mono-olefins, with substances having a double bond between 2 C atoms conjugated with 1 or more  $\text{COOH}$  or  $\text{CO}$  groups, e. g., maleic acid or anhydride, crotonic acid, crotonaldehyde, acrolein or quinone, and recovering the substituted acids or carbonyl compds. from the reaction mass. The products may be used as such or converted with other substances into synthetic resins, pharmaceutical preps., plasticizing means, lacquers or insulating materials. Among examples (1) amylene (produced from fermentation  $\text{AmOH}$ ) is heated in an autoclave to  $180^\circ$  with maleic anhydride (I) and the product treated with lye and then pptd. with a mineral acid, e. g.,  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ , to produce amylesuccinic acid and (2) cracking benzene, e. g., vapor phase cracking benzene, is heated in an autoclave at  $200^\circ$  with I and the substituted succinic acid formed is recovered as in (1).

**Condensation products from urea, thiourea, and formaldehyde.** The British Cyanides Co. Ltd. Ger. 583,262, Sept. 4, 1933. See Brit. 206,028 (C. A. 22, 505).

**Plastic composition.** Robert C. Korf. Ger. 583,176, Aug. 31, 1933. A soln. of natural or synthetic resin in borax soln. is mixed in the cold with fillers, pigments and metal salts or oxides (none specified) to produce a plastic mass which hardens in the air and can be used for interior decoration, etc.

**Plastic compositions.** Soc. des brevets étrangers de la Neoxyle. Ger. 583,374, Sept. 2, 1933. An org. or inorg. filling material is mixed with about 0.5 mol. of  $\text{H}_2\text{SO}_4$  (as 5%  $\text{H}_2\text{SO}_4$ ) and 5 mols. of  $\text{HCl}$  (as 20%  $\text{HCl}$ ), and the mixt. is treated with an aq. or anhyd. mixt. of about 4 mols. of  $\text{CaO}$  with  $\frac{1}{2}$  mol. of  $\text{ZnO}$ . The whole mixt. is then molded under pressure and dried. Addn. of powd. Al and a carbohydrate to the mixt. is advantageous.

• **Plastic compositions comprising cellulose derivatives and synthetic resins.** James F. Walsh and Amerigo F. Caprio (to Celluloid Corp.). U. S. 1,930,069, Oct. 10. A compn. suitable for the manuf. of sheets, etc., comprises a cellulose deriv. such as cellulose acetate and a plasticizer such as triphenyl phosphate in such quantity that exudation would normally occur, together with a synthetic resin such as one formed from toluenesulfonamide and formaldehyde in a quantity of 1-20% that of the plasticizer, which serves to prevent exudation and otherwise improves the properties of the product.

**Plastic compositions from dihaloparaffins and polysulfides.** Nathan Maxwell Mookin. Ger. 583,277, Aug. 31, 1933. See Brit. 350,456 (C. A. 26, 5302).

**Adhesives.** Stockholm. Bunnjolsfabriks Aktiebolag. Brit. 394,517, June 29, 1933. A dry flexible adhesive film consists of bone glue or a mixt. thereof with hide glue. Small quantities of potato starch may be added. The film may be made by mulling a viscous glue compn. between rollers and it may be reinforced with paper or fabric by immersing the latter in the liquid glue compn. and drying. The film may be used for veneering, heat and pressure being used to transform it to a viscous mass which sets on cooling. Glycerol, glucose and K lactate may be added to promote the change to a viscous state.

**Cement.** Siemens & Halske A.-G. (Reinhold Reichmann, inventor). Ger. 583,347, Sept. 1, 1933. A cement, particularly useful for securing the middle electrodes of spark plugs, is prepd. by mixing with water glass soln. a compn. comprising  $Al_2O_3$  50-53,  $Al(OH)_3$  10, powd. quartz 16, and powd. Pb glass 2.5 parts.

**Sheets or films.** I. G. Farbennud. A.-G. Brit. 394,244, June 22, 1933. The mech. properties of sheets or films prepd. from solns. of artificial polymerization products of a high degree of polymerization are improved by freeing them, by treatment with an org. liquid, from the solvents and softening agents (if any) still present, without dissolving the polymerized products themselves. Among examples a film cast from a soln. of polyvinyl chloride in a mixt. of cyclohexanone is extd. with MeOH, a mixt. of MeOH and BuOH and  $C_2H_6$ .

**Compound sheet materials.** Arthur Lichengrun. Brit. 394,753, July 6, 1933. Lacquer-like coatings on flexible materials are produced by applying by means of heat and pressure thin foils of thermoplastic material having a thickness of 0.01-0.05 mm. The flexible base may be paper, cardboard, fabrics, leather, metal foil, celluloid, synthetic resins, galalith or artificial cork made from disintegrated cork and nitrocellulose. Suitable thermoplastic materials are cellulose derivs., e. g., the nitrate, acetate, formate, propionate or butyrate and Et, Me or benzyl cellulose, which may contain plasticizers and synthetic resins. The foils may be colored and a plurality of foils having different compns. and consequently different softness may be superposed and pressed in 1 operation. Washable paper may be thus produced.

**Decorative panels.** Dulcie G. Vaughan, Alfred G. Larter and Albert F. Wagstaff (trading as Enterprise Glass Co.). Brit. 393,184, June 1, 1933. Decorative panels are made by placing between 2 sheets of glass a sheet of fabric, celluloid or cellulose acetate on which an illustration has been painted, applying to the assembly by dipping, brushing or spraying a mixt. of methylcyclohexanol acetate and Et phthalate and finally heating under pressure.

**Cleansing composition.** Dreitur-Seifenfabrik Viktor Wolf (Michael Lewinsohn, inventor). Ger. 584,477, Sept. 20, 1933. A compn. for removing grease from household articles, etc., contains an alkali or alk. earth acetate and a subordinate amt. of silica or water glass, with or without other usual components. A typical compn. contains NaOAc 25, borax 20, cryst. soda 50 and water glass 5%.

**Cleansing composition for wallpaper, painted surfaces, etc.** Herbert Walter. Ger. 584,312, Sept. 18, 1933. Coarse rye flour is treated with two thirds of its wt. of hot dil. aq. water glass soln.

**Wetting agents, etc.** Deutsche Hydrierwerke A.-G. Pr. 750,547, Aug. 14, 1933. Unsubstituted or mono-substituted amines, in which one at least of the radicals joined to N is composed of a hydrocarbon radical of high mol. wt. of the fatty or alicyclic series, are transformed to halogenated amides by treatment with halogenated carboxylic acids having one or more mobile halogen atoms or with their anhydrides or chlorides, and then one or more of the halogen atoms are replaced by sulfonic groups. Examples are given of the prepn. of cetylpropionamide- $\beta$ -sulfonic acid ( $C_{16}H_{33}NHC(=O)CH_2CH_2SO_3H$ ), dodecyl(hydroxyethyl)acetamidesulfonic acid ( $C_{12}H_{25}N(CH_2CH_2OH)C(=O)CH_2SO_3H$ ) and naphthylacetamidedisulfonic acid. The products are wetting, dispersing, cleansing and foam-producing agents.

**Emulsifying and dispersing agents.** Henry Dreyfus. Brit. 391,657, June 19, 1933.  $H_2O$ -insol. compds. are emulsified or dispersed in  $H_2O$  by means of the esters, amides or ester-amides obtained by condensing amino-acids with naphthene or resin acids, e. g., of colophony and various copals or the synthetic resin acids prepd. by condensing natural resins with phenol-aldehyde and urea aldehyde condensation products, glyptal resins and the products obtained by condensation of aliphatic dicarboxylic acid, e. g., sebacic, with alic. The esters or amides may contain  $HSO_3$  groups and, when a free COOH group is present, may be converted into the Na, K or NH salts or esterified with other alics. They are particularly useful for making aq. dispersions of dyes for dyeing and printing textile fibers, especially cellulose fibers, and for dispersing lakes and pigments for use as aq. paints. Ammonoles mentioned are mono-, di- and tri-ethanolamine, diaminopropanol, dihydroxypropanolamine, butanolamine, pentanolamine and such compds. as made by the action of ethylene oxide on ethylcucdiamine. An example is given of the dyeing of cellulose acetate fabric with a dispersion of 1-amino-4-methylaminoanthraquinone prepd. by grinding the dye with the condensation product of naphthene acid and ethanolamine in the presence of  $H_2SO_4$  and stirring the mixt. into  $H_2O$ .

**Non-resonant surfaces.** Michel & Marchal. Brit. 394,927, July 6, 1933. Non-resonant surfaces are obtained by treating the surface with a layer of adhesive and depositing pulverized vegetable or animal textile fibers thereon. A suitable adhesive comprises stand oil 25,  $CaCO_3$  45, synthetic resin 3, mineral oil 22.5,  $PbO$  0.5 and siccativ with Mn and Co 1%.

**Materials for duplicating rolls.** Carl S. Miner (to Charles H. Joy, Jr.). U. S. 1,929,601, Oct. 10. A backing material such as paper is coated on both sides with lacquer, a binding agent contg. solvents for both lacquer and duplicating compn. is applied to at least one lacquer coating, and a duplicating compn. is applied over the binding agent.

**Friction composition for brakes.** American Brake Materials Corp. Ger. 583,461, Sept. 4, 1933. See U. S. 1,882,702 (C. A. 27, 820).

**Puncture sealing compositions.** Arthur W. Dickeson and Clara E. Dickeson. Brit. 394,978, July 4, 1933. The compn. comprises a filler mixt. of ground mica, teased asbestos fiber, French chalk (or tripoli, whitening or asbestos powder), ground cork (or ground rubber) and matted human hair. It is used in conjunction with a film-forming agent consisting of tragacanth "sorts," agar agar and formalin soln.

**Chewing gum base.** John O. Barker (to Sweet's Laboratories, Inc.). U. S. 1,930,436, Oct. 10. A caustic alkali soln. is added to latex and the mixt. is allowed to stratify into layers; the rubber contg. layer is sepd. and other chewing gum components are added to it.

**Dental fillings.** Sally Oppenheim. Brit. 394,260, June 22, 1933. A dental root-canal filling consists of a mixt. of 2 different powd. metals, e. g., Ag and Au, mixed with an electrolytic liquid, e. g., the  $H_3PO_4$  used as a binder for the cement that holds the filling in place.

**Sound records.** Laurence Fisher. U. S. 1,931,287, Oct. 17. A disk of fibrous material such as cardboard

is treated on both sides with a sizing and a glue wash is applied to the sizing. Two disks of cellulose ester composition such as cellulose nitrate or acetate are treated on one side with a "cellulose" soln which is a thermally reactive adhesive and the other sides of the cellulose ester disks are treated with a soln of bronzing liquid contg pulverized silica and a filling powder such as soapstone, whiting and soap. Disks of paper are placed between opposite sides of the fibrous disk and the adhesive-treated sides of the cellulose ester disks, and sound lines are impressed under the action of heat and pressure on the assembled materials.

**Apparatus for blowing slag to form artificial pumice stone** Carl H Schol Ir 750,610, Aug 11, 1933

**Printing-surfaces** Henz Horn Brit 395,214, July 13, 1933 Rubber forms for relief and intaglio printing are produced by supplying the matrices or original forms

with natural or synthetic, thinly or thickly liquid or paste like rubber milk which may be mixed with fillers, (e.g., chalk, ZnO, Zn or other metal dust, cement, powdered cork, heavy spar and S, and may be hardened by vulcanizing at normal temp or in an oven at 115°. The milk may be vulcanized, concd or mixed with suitable substances to render it microporous before it is applied. The matrix or original form is preferably coated with a thin layer of rubber-repellent substance, (e.g., gelatin, chalk).

**Foam-producing compositions for extinguishing fires** Felix Neville Ger 543,231, Aug 31, 1933 Comps of the known kind comprising an anhyd carbonate,  $Al_2(SO_4)_3$ , a foam-producing agent, and a dehydrating agent are improved as regards stability to storage by using anhyd  $Al_2(SO_4)_3$  and an anhyd foam-producing agent. Anhyd  $NaHSO_4$  may replace a part of the  $Al_2(SO_4)_3$ .

## 19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

F BARTOW C H KEIR

**Venetian art glass** Robert Schmidt *Glastech Ber* 11, 324 (1933) J I Hyde

**Old Thuringian cut glass** Gustav I Paurick *Glastech Ber* 11, 325 (1933) J I Hyde

**Essentials of glass technology based on American practice** Samuel R Scholes *Ceram Ind* 21, 242-52 (1933), cf C 1 27, 591, Herbert S Willson

**A peculiar attack on chemical glassware by dilute aqueous ammonia** Franz Hundt *Glastech Ber* 11, 323 (1933) On standing several months there was a skin of hydrated amorphous silica, accompanied by small nodules. The base of these were brownish black and consisted of  $MnO$ . The remainder of the nodules was made up of calcite crystals. Thus considerable  $Mn$ , lime, alkali and silica had been extd. J I H

**The coloring of glasses with copper selenium and sulfur** Hermann Weckerle *Glastech Ber* 11, 273-8, 314-23 (1933) The study of the Cu ruby was carried out on a base glass of the compn  $SiO_2$  50.43,  $PbO$  21.2,  $CaO$  0.09,  $Na_2O$  7.49,  $K_2O$  5.33,  $B_2O_3$  0.05,  $Li_2O$  0.08%. Cu was introduced in the form of  $Cu_2O$  with Sn as the reducing agent. The amt of  $Cu_2O$  was varied from 0% to 9% and the Sn from 0% to 6%. The time and temp of heat treatment required to produce coloring and liveness were directly proportional to the amt of Cu present. An analysis of colors, ruby and liver glass showed the Cu to be present as metal and oxide in nearly equal amts, so that the difference must be largely phys., such as particle size. This, together with ultra-microscopic examn, substantiates the theory that the colorless glass contains only crystal centers which grow by pptn of the dissolved Cu on proper heat treatment to give the ruby and finally livering. A glass of the compn  $SiO_2$  55.9,  $Na_2O$  2.1,  $K_2O$  15.0,  $CaO$  7.0%, was used in the study of pure S glasses. Addn of  $Na_2SeO_3$  with a reducing agent failed to give any color but brown. The compn of the glass used in the study of the Se Cd sulfide ruby was  $SiO_2$  58.58,  $B_2O_3$  2.19,  $PbO$  0.31,  $Na_2O$  3.4,  $K_2O$  14.06,  $CaO$  4.21,  $ZnO$  16.21%. Omission of  $B_2O_3$  and  $PbO$  did not affect the color. Replacement of K by  $Na$  shifts the color toward yellow. Replacing  $ZnO$  by  $Al_2O_3$  or  $CaO$  results in colorless or brownish glasses. Leaving out  $CdS$  gives colorless glasses. Cd introduced as oxide also gives a colorless glass. With  $CdSe$  added, in amts equiv to the usual amts of  $CdS$ , to the normal Zn-contg glass good ruby glass resulted. The amt of Cu remaining in a glass was directly dependent on the Zn content. It is definitely shown that Zn, Cd and Se are all essential to the production of a ruby glass. The Se may be introduced as  $Se$ ,  $Na_2SeO_3$  or  $CdSe$ , and the Cd as  $CdS$  or  $CdSe$ . The S is in any case unnecessary. For S yellow glasses the following compn was used:  $SiO_2$  42,  $Na_2O$  18% with small addns of sulfate and C. The  $SiO_2$  obtained from  $Na_2SiO_3$  was iron free and the melting done in Pt. The yellow color due to C is weak, hard to reproduce, and therefore of no significance. The real

yellow to deep brown colors are the result of introduction of S. The pure melt was colorless showing the absence of any color due to Na S. The variation in color with  $Fe$  content was studied. The  $Fe$  has no influence on the (sulfide) S content of the glass. Forty-two references. J F Hyde

**Studies on the heat currents in tanks by means of models** Adolf Schild *Glastech Ber* 11, 305-14 (1933) Transparent oil of the proper viscosity, in conjunction with dye, was used to simulate glass in model tanks of various types. The behavior of the currents is amply illustrated by sketches and photographs. J F H

**Scientific principles of fuel economy in the glass industry** The importance of low-grade town gas David Brown *Glass* 10, 108-11 (1933), cf C 4 27, 5932

Herbert S Willson

**Is glass a rigid substance?** Hugo Kuhl *Glastech Ber* 63, 155 (1933) —Seemingly rigid and brittle glass is more or less elastic and plastic. Elasticity and plasticity depend on the compn and working of the glass melt. Inhomogeneity of the glass is the reason for an increased brittleness and depends on the prepn of the batch, melting and working of the glass. The compn of the glass is very significant for the rigidity of its structure, for its elasticity, and hence, for its plasticity. Alumina glasses are very viscous and elastic glasses rich in Pb are very viscous and plastic. Viscous and elastic glasses have a high impact strength and are resistant to pressure. Plasticity is a relative property of glass. Every glass is plastic in the softened state and is only distinguished by the height of temp necessary to bring about the plastic state. The more elastic the glass is, the smaller is its plasticity. The crystal processes producing devitrification in old glasses show that the arrangement of the mol. and their position changes. These phenomena are not conditioned by newly originated formations of crystals but by the growth of those present. This transformation of glasses is considerably affected by their compn and working. Certain optical phenomena stipulated by chem reactions confirm the relative movement of mol. in glass assumed to be rigid. Rays acting chemically release chain processes in the glass. Another confirmation of the mobility of seemingly rigid mol. is shown by the fluorescence of glasses contg Cu when exposed to Röntgen rays and the violet coloring of Mn glasses originally colorless.

Pipet analyzer of Krausz. O. Sommer. *Ber. deut. keram. Ges.* 14, 193-7 (1933). A new app. is described for measuring the fineness of grain of clay by the pipet sedimentation method.

Notes on the x-ray diffraction patterns of mullite. K. Posnjak and J. W. Gray. *J. Am. Ceram. Soc.* 16, 569-83 (1933).—Various artificial  $Al_2O_3 \cdot SiO_2$  products, also clay minerals and clays heated to 1000°, were examined by the x-ray powder method. All patterns identified were mullite, not sillimanite. Mullite crystal conts.  $Al_2O_3$ ,  $Fe_2O_3$  or  $TiO_2$  in solid soln gave patterns with lines slightly displaced toward the origin. Mullite crystals, freed by HCl from the matrix, often gave patterns in which the intensity of certain lines was much different from normal, because of the orientation of the minute, etched crystals when mounted for photographing. No basis is found for claims of the discovery of similar materials for which new names have been proposed.

Melting ranges of silica-glass oxide systems and some conclusions. M. Hollnagel and H. Rumpf. *Ingew. Chem.* 46, 662-7 (1933). The phase diagram of  $SiO_2$  glass oxide systems was investigated, which contained the glass oxides in the following mol. proportion: (1) 0.3  $K_2O$ , 0.7  $Al_2O_3$ , 0.7  $CaO$  and, for lower melting concs., (2) 0.3  $K_2O$ , 0.3  $Al_2O_3$ , 0.7  $CaO$ , 0.7  $PbO$ . It was found that the system contg. 42.125% glass oxide mol., the balance being  $SiO_2$ , after melting, form pure phys. solns of these oxides in  $SiO_2$ . The proof of the fully anisotropic state of the melt is established by Dbye diagrams. The system with less than 12.5% glass oxide mol., after melting, consist of mixed crystal, where the oxide mol. are probably interspersed in the quartz lattice. Well-formed interference figures at the Dbye diagrams of the melts prove their crystal character. Only at the m. p. of the mixt. contg. 12.5% glass oxide mol., 1472°, do 3 phases exist in equil. In the melting range of the other mixts. only 2 phases exist, the solid amorphous or the solid crystal and the liquid phase. These observations hold only within the melting range and slightly below it, as on cooling, some pure  $SiO_2$  always crystallizes out. The point of separation into  $SiO_2$  and  $SiO_2$  glass oxide mixt. lies lower for greater quantity of dissolved glass oxide mol.

An investigation of the refractories used in ladles and in ingot casting. I. Some characteristics of the clays used in the manufacture of runners, stoppers, nozzles, etc. J. R. Prastly and W. J. L. *J. Soc. Chem. Ind.* 52, 297-304 (1933).—Fine clays from the Sheffield district showed a shrinkage up to 1100°, then a slight expansion around 1200°, then further shrinkage until permanent bloating begins at 1300°. This expansion at 1200° may be due to mineralogical changes or to a premature bloating. The mineralogical exams have not been completed, but porosity and sp. gr. data indicate that the expansion is due to an increase in the closed pores.

Test for chemical resistance of glass containers. F. C. Flint and A. K. Lyle. *Bull. Am. Ceram. Soc.* 12, 296-9

(1933).—A simple NaOH and an autoclave test are described.

Air-cooled enamel. Vielhaber. *Emailwaren-Ind.* 10, 303-4 (1933).

Practice in the enamel shop, efficiency of heat transfer. Ludwig Stuckert. *Ceram. Age* 22, 102-3 (1933); cf. *C. A.* 27, 1645. Bibliography.

Sintering of the lining of rotary kilns for fusing enamel. Karanus. *Emailwaren-Ind.* 10, 285-7 (1933).—Directions are given.

Majolica enameling according to the wet and powder methods. Lang. *Glashutte* 63, 204-6 (1933).—Four methods for applying powder and the wet method are described.  $SiO_2$  (2.4%) is the best opacifier for the round coat in the wet method. Attempts to use  $SnO_2$  were unsatisfactory, it produced bubbles and dark spots.  $SiO_2$  increased the adherence of the ground coat. Fluorides should not be used in the ground coat when the wet method is employed.

Manufacturing defects and mechanical damages in wet process porcelain enamelware. Edward Dahill. *Bull. Am. Ceram. Soc.* 12, 317-18 (1933).

Waste in enamel works. H. Motscham. *Emailwaren-Ind.* 10, 284-90 (1933).

Leakage in horizontal gas retorts [also in fireclay retorts]. (Lucas) 21. Uses of coal in the ceramic industry (Nold) 21. Joints between metal and siliceous refractories (Brit. pat. 394,311) 9.

Littleton, J. T., and Morey, G. W. Electrical Properties of Glass. Monograph No. 3, Natl. Research Council Series. New York: John Wiley & Sons, Inc. 184 pp. \$3.00. Reviewed in *Ind. Eng. Chem.* 25, 1408 (1933).

Electric furnaces for making glass, etc. Harold W. McIntosh (to Hartford-Empire Co.). Brit. 394,709, July 3, 1933. In the production of glass, sol. Na silicate and vitreous enamels the graphite electrodes are coated with the substance to be made before insertion in the furnace so that they are not oxidized and the product consequently discolored.

Resistance furnace, with auxiliary gas burner, for glass manufacture. Patent-Inchard Ges. fur Glask. Glash. Lampen u. H. Ger. 584,389, Sept. 19, 1933.

Tank furnace for glass manufacture. Deutsche Glas- u. Owens Ges. fur maschinelle Glasherstellung A.-G. Ger. 581,388, Sept. 19, 1933.

Means for preventing formation of bubbles in molten glass. Leopoldo Sanchez Vello. Ger. 584,163, Sept. 15, 1933. See Brit. 379,216 (*C. A.* 27, 2551).

Apparatus for manufacture of hollow glassware such as bottles. Clyde C. Cook and Charles Badger (to Owens-Ill. Glass Co.). U. S. 1,931,375, Oct. 17. Mech. features.

Apparatus for making glass articles such as bottles. Hartford Empire Co. Fr. 750,558, Aug. 12, 1933.

Apparatus for the manufacture of glass containers such as jars and bottles. Arthur C. Forster. U. S. 1,920,842, Oct. 10. Mech. features.

Apparatus for forming glassware such as bottles. Henry W. Inck (to Hartford-Empire Co.). U. S. 1,930,139, Oct. 10. Mech. features.

Apparatus for forming glassware such as bottles. Willard L. Van Ness (to Owens-Ill. Glass Co.). U. S. 1,931,336, Oct. 17. Mech. features.

Apparatus for making glass filaments. Borukes and Brenner und Glasmaschinen G. m. b. H. Ger. 584,215 and 584,216, Sept. 16, 1933.

Apparatus for making glass strip with a surface of colored glass. Deutsche Spiegelglas-A.-G. Ger. 584,214, Sept. 16, 1933.

Continuous apparatus for drawing glass or wired glass strip. Hugo Knoblauch. Ger. 584,015, Sept. 13, 1933, and 584,391, Sept. 19, 1933.

Apparatus for sheet-glass manufacture. Paul J. M. Escole (to Forges et ateliers de constructions electriques

de Jeumont, Soc. anon.). U. S. 1,930,424, Oct. 10. Mech. features.

**Preventing blurring or dulling of sheet glass.** "Mühlig-Union" Glasindustrie A.-G. Brit. 394,635, June 29, 1933. The dulling or corrosion of sheets or plates of glass, due to the action of condensed moisture, is prevented by treating their surfaces with a medium, e. g.,  $\text{CuSO}_4$ ,  $\text{FeSO}_4$ , citric acid,  $\text{H}_2\text{BO}_3$ , that neutralizes the alkalies extd. by the moisture. The medium may be incorporated with a carrier adapted to be spread thinly off the surface, e. g., asbestos, sawdust, etc. Paper, satd. with a soln. of 1 g.  $\text{FeSO}_4$  per 1.  $\text{H}_2\text{O}$ , may be used for sepg. glass sheets when packed or stacked.

**Method of hardening sheet glass by blowing with air.** Société anon. des manufactures des glaces et produits chimiques de St. Gobain, Chauny & Cirey. Ger. 584,217, Sept. 16, 1933.

**Apparatus for drawing glass tubes.** Soc. anon. "Le Pyrex." Ger. 584,162, Sept. 15, 1933.

**Roller for flat-glass-drawing machines.** Joseph Gaskell (to Pilkington Bros. Ltd.). U. S. 1,930,999, Oct. 17. Mech. features.

**Glass transparent to ultra-violet rays.** Sendlinger optische Glaswerke G. m. b. H. (Georg Jacekel, inventor). Ger. 583,001, Aug. 20, 1933. Glass of high transparency to ultra-violet rays contains  $\text{BaO}$  at least 10 and  $\text{B}_2\text{O}_3$  not more than 10%, and not more than 3.5 mols. of acid ( $\text{SiO}_2 + \text{H}_2\text{O}$ ) per mol. of base ( $\text{BaO} + \text{Na}_2\text{O}$  and/or  $\text{K}_2\text{O}$ , with or without  $\text{ZnO}$ ). The glass contains no  $\text{As}_2\text{O}_3$  and practically no  $\text{Fe}_2\text{O}_3$  and preferably no  $\text{CaO}$ . A specified compn. is  $\text{SiO}_2$  59,  $\text{B}_2\text{O}_3$  4,  $\text{Na}_2\text{O}$  7,  $\text{K}_2\text{O}$  7,  $\text{BaO}$  10 and  $\text{ZnO}$  4%.

**Apparatus and process for the formation of flashed glassware by pressing.** Glashüttenwerke vormals J. Schreiber & Neffen. Brit. 395,599, July 20, 1933.

**Rolling machine for making wire glass.** Chance Brothers & Co. Ltd., Wm. H. S. Chance and Leonard Garman. Brit. 394,783, July 6, 1933.

**Press for making nonsplintering glass.** Carl Schaefer. Ger. 584,171, Sept. 15, 1933.

**"Acid-grooving" of safety glass.** Brook J. Dennison (to Duplate Corp.). U. S. 1,930,587, Oct. 17. For removing the periphery of a sheet of cellulose deriv. material such as cellulose acetate compn. lying between a pair of glass sheets in a laminated plate, the plate is submerged in a bath of  $\text{H}_2\text{SO}_4$  contg. an oxidizing agent such as  $\text{HNO}_3$ .

**Laminated glass.** Joseph G. Davidson (to Carbide & Carbon Chemicals Corp.). U. S. 1,929,352, Oct. 3. Glass sheets are united by a layer composed of a polymerization product of an ester of vinyl alc. such as polymerized vinyl acetate which adheres directly to the glass.

**Non-drip vessels.** Corning Glass Works. Brit. 394,918, July 6, 1933. The underside of the rim or lip of a glass or pottery vessel is coated with a transparent, fired-on film of a metallic compd. that resists wetting by aq. solns., dripping being thus prevented when pouring therefrom. Suitable materials for the coating are  $\text{TiCl}_4$ ,  $\text{SiCl}_4$ ,  $\text{SnCl}_4$  and  $\text{FeCl}_3$ . Cf. C. A. 27, 4646.

**Composite articles of fused silica or the like.** Elihu Thomson (to General Elec. Co.). U. S. 1,930,327, Oct. 10. Articles such as large telescope mirrors are formed by accretion from particles of  $\text{SiO}_2$  or the like fed into a fusion zone at such a rate, during formation of a portion of the article, that a dense transparent product results, and, subsequently, at a higher rate by which a less transparent and less dense product is formed. Cf. C. A. 27, 1471.

**Composite articles, such as large telescope mirrors, of fused silica.** Alvarado LeR. Ellis and Gunnar A. F. Winckler (to General Elec. Co.). U. S. 1,930,340, Oct. 10. Otherwise homogeneous articles such as telescope mirrors are formed in part of transparent vitreous silica having a d. of about 2.2 and substantially devoid of gas inclusions, and in part of a translucent material contg. gas inclusions and having a d. of about 2.0.

**Manufacture of pyroxylin tubing.** Cecil J. Carroll

(to Nizon Nitration Works). U. S. 1,930,995, Oct. 17. Various details of app. and operation are described.

**Purifying clay.** David F. McCormick (to Kaolin Processes Inc.). U. S. 1,930,247, Oct. 10. Clay is purified by disintegrating, drying and air-sepg. a part of the clay from its impurities, and washing the rejects of air sepg. contg. pure clay for recovering substantially the balance of pure clay, these operations being carried out successively on a constantly moving stream of clay (in a described app.).

**Ceramic compositions.** A C Spark Plug Co. (Hans Navratil and A. H. Fessler, inventors). Ger. 583,003, Sept. 1, 1933. See Brit. 322,361 (C. A. 24, 2853-4).

**Apparatus for extruding hollow bricks, etc.** Heinrich Supthut (trading as the firm Wilhelm Schülke) and Paul Thomas. Brit. 395,341, July 4, 1933. Addn. to 380,591 (C. A. 27, 5503).

**Porous bricks and pottery.** Aage Nielsen. Ger. 583,301, Sept. 1, 1933. See Fr. 735,954 (C. A. 27, 1471).

**Pottery product suitable for chemical work, etc.** Max Hauser. U. S. 1,930,095, Oct. 10. A container having acid-resisting properties, high-thermal cond. and high resistance to breakage from temp. changes has walls comprising a fired mixt. of discrete particles of finely ground or granular  $\text{Si}$  bonded by a matrix of ceramic raw material of the silicate type such as may be formed from clay, etc.

**Products such as bent tubes or rods from plastic materials such as fire clay, etc.** Louis C. Bonnot (to Bonnot Co.). U. S. 1,931,371, Oct. 17. A mass of plastic material is homogenized by degasifying, and subsequently formed and reshaped.

**Gramophone needles.** Jack F. Jordan. Brit. 394,823, July 6, 1933. Needles for gramophones, etc., are made of burnt clay, preferably by drying to a plastic condition a colloidal suspension obtained by washing out the coarser ingredients, drying further and heating to a sintering temp. about 10-12 hrs. An analysis of a suitable clay is given.

**Refractories.** Alterra A.-G. Brit. 394,115, June 22, 1933. Refractory sintered  $\text{MgO}$  is produced from raw materials low in  $\text{Fe}$  by adding to the charge a small proportion of preformed  $\text{CaFe}_2\text{O}_4$  or  $\text{CaO}$  and  $\text{Fe}_2\text{O}_3$  (or substances yielding these) in such proportions that the  $\text{CaO}$  does not exceed that necessary to form  $\text{CaFe}_2\text{O}_4$ , addns. other than  $\text{CaO}$  and  $\text{Fe}_2\text{O}_3$  being made, or being present as impurities, only in such quantities that the formation of  $\text{CaFe}_2\text{O}_4$  is not impeded. The  $\text{CaO}$  may be present in the raw material as impurity. Where the raw material contains acid silicates, or substances yielding acid silicates on calcination, sufficient basic material is added to combine therewith, and if  $\text{CaO}$  is added for this purpose, sufficient excess must be added to combine with the added  $\text{Fe}_2\text{O}_3$ . In an example magnesite, poor in  $\text{CaO}$ ,  $\text{SiO}_2$  and  $\text{Fe}$ , is mixed with 15%  $\text{CaO}$  and 5%  $\text{Fe}_2\text{O}_3$  and fired at 1350°.

**Refractory ceramic articles.** Deutsche Ton- & Steinzeug-Werke A.-G. Ger. 583,195, Aug. 31, 1933. Articles made from an ordinary ceramic compn. are provided with an internal supporting framework of a material more highly resistant to temp. and pressure and of similar compn. Thus, a standard compn. comprising chamotte and clay may be molded around a framework of  $\text{SiC}$  and then fired in the usual way. The products retain their shape when subjected to a bending force at a high temp. and pressure.

**Refractory compositions.** Victor M. Goldschmidt (Rudolf Knudsen, co-inventor). Ger. 583,194, Aug. 31, 1933. Comps. consisting mainly of  $\text{Mg}$  orthosilicate are prepd. by heating talc with  $\text{MgO}$  or magnesite to a temp. insufficient to fuse the mixt., e. g., to 1300-1450°. Natural  $\text{Mg}$  orthosilicate may be added to the initial mixt.

**Cast refractory bricks for Siemens-Martin furnaces, etc.** Arthur Sprenger. Ger. 583,125, Aug. 29, 1933. Constructional features are described.

**Waterproof abrasive articles.** Zoltan Hadnagy, Albert Bouillard and Andre Auby. Brit. 394,442, June 29, 1933. The articles, e. g., sand paper, emery cloth, etc.,

are made by use of an adhesive consisting mainly of material elastic at normal temp., melting or softening at about 100° and solidifying in a few sec. on natural cooling. Suitable substances are oils treated with S, stearin pitch, gutta-percha, balata with or without oil, partially oxidized or polymerized oils, e. g., linolin, mordant or blown oil,  $C_{10}H_8$  and S and to these may be added resins, wax or a mixt. of synthetic and natural resin. App. is described for prepg. abrasive paper.

**Abrasive tools for grinding, lapping and finishing of metals.** Joseph N. Bethel (to Norton Co.). U. S. 1,931,370, Oct. 17. Tools such as burs, disks or wheels are formed of a molded compacted mixt. of sep. and distinct particles of granular metal such as brass, Al, Sn or Pb and granular abrasive material such as SiC or emery held in position by a brittle, non-metallic bond such as shellac or Na silicate which has been heat-set to form an integral body. Cl. C. A. 27, 4050.

**Machine for testing abrasive qualities of materials and for testing lubricants.** The Timken Roller Bearing Co. Brit. 395,976, July 27, 1933.

**Adhesive for use in manufacture of waterproof abrasive products such as abrasive cloth or paper.** Jacques Lemerle (to Société anon. compagnie centrale des emeris et produits a Polir). U. S. 1,930,393, Oct. 10. An oxidized drying oil such as oxidized linseed oil is mixed with about 4% of a bitumen material such as asphalt.

**Enameling.** The Porcelain Enamel and Manufacturing Co. of Baltimore. Brit. 395,482, July 20, 1933. Vitreous enamelled articles having a multicolored appearance are produced by forming a rough surface on an article, applying colors to the surface so that the article appears of different color when viewed from different directions and then firing to produce a smooth surface. Comps. of suitable enamels are given.

**Coating metal surfaces such as steel or iron.** Ford C. Zimmer (to General Elec. Co.). U. S. 1,930,331, Oct. 10. A corrodible metal surface such as steel or iron is provided with a ground coat of vitreous enamel and a superposed protective and decorative coat of an org. finishing material such as a synthetic resin varnish entirely covering the ground coat.

## 20 CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

**Cement.** H. H. Hughes and B. W. Bagley. *Bur. Mines, Minerals Yearbook 1932* 33, 565 75(1933).

**Rapid analysis of portland cement.** P. N. Grigoriev. *Z. anal. Chem.* 94, 249 51(1933).—First det. the loss on ignition in a Pt crucible. Digest the ignited product with 3-5 cc. of HCl and heat to gelatinize the hydrated  $SiO_2$ . Cool, dil. with water and filter off the ppt. without dehydrating. For this a membrane filter is recommended. Divide the filtrate into 3 aliquot parts. In one det. the  $Fe_2O_3$  content by the Zimmermann-Reinhardt method. In a second part, ppt. with  $NH_4OH$  and weigh the ignited ppt. of  $Fe_2O_3$  and  $Al_2O_3$  in the usual way. In the filtrate from this pptn. det.  $SO_4^{2-}$  by the rhodizomate method, as follows: neutralize, add an excess of 0.5 N  $BaCl_2$ , shake repeatedly, add 2 cc. of  $HCl$  and 10 drops of Na rhodizomate and titrate the red soln. with 0.2 N  $(NH_4)_2SO_4$  to det. the excess  $Ba^{++}$ . In the third aliquot det.  $CaO$  and  $MgO$ . To do this, heat to boiling without neutralizing, add  $NH_4OAc$  and  $(NH_4)_2C_2O_4$ , filter off the resulting  $CaC_2O_4$  and titrate with  $KMnO_4$  in the usual way. In the filtrate ppt. the  $Mg$  as  $MgNH_4PO_4$  and titrate the ppt. with 0.1 N  $HCl$  by the method of Killig. The entire analysis can be completed in 7-8 hrs.

**Preparation and properties of anhydrite cement.** Peter P. Budnikov. *Chem.-Ztg.* 57, 801 3(1933).—Addn. of small amts. of  $NaHSO_4$  and  $CuSO_4$  to dead-burnt gypsum results in a product that may be rehydrated to a cement having a tensile strength above 40 kg./sq. cm. after a month. G. B. Taylor

**Porcelain cement for cable mountings.** St. Reiner. *Chem. Fabrik 1933*, 461 2. Directions are given for making phys. tests of cements, with some results. J. H. M.

**Special low-heat cement for mass concrete dams.** Samuel B. Morris. *J. Am. Water Works Assoc.* 25, 1350 61(1933). Concrete of high early strength is not necessary. Low heat of hardening is usually coupled with durability. Constancy of vol., high d. and strength reduction of cement used reduce the heat of setting. Specifications are outlined and explained. D. K. F.

**Volume changes of concrete.** Edmour Chauret. *Rev. trimestr. can.* 19, 311-30(1933).—The influence of the following factors upon vol. changes of concrete are discussed: (1) chem. compds. in portland cement and possible reactions and mechanism in the setting and hardening process, (2) heat, (3) water, (4) freezing, (5) phys. action of dissolved salts, and (6) chem. action of dissolved salts. Vol.-change curves of cement test bars over test periods of 18 20 years, for repeated immersions in  $H_2O$ , and short-time tests extending over 60

days including observations for the first appearance of cracking are presented. Fourteen references. K. K.

**Note on the possible attack of concrete-reinforcing iron by blast-furnace cement.** Paul Proulx. *Chimie & Industrie Special No.*, 820 1(June, 1933).—Examin. of the Fe removed, after 10 yrs. service, from concrete consisting of slag lumps, granulated slag and slag cement, showed that its surface was not attacked. Expts. on the elec. potential of blast-furnace cement confirmed its suitability for this purpose. A. Papineau-Couture

**Development and use of a Canadian plastic magnesia.** A. F. Gill. *Can. Chem. Met.* 17, 200 3, 208(1933).—Plastic magnesia as used with  $MgCl_2$  soln. for the production of oxy-chloride cement is obtained by the "caustic" calcination of Mg-bearing carbonate rock. It possesses a comparatively high degree of chem. activity, caused by the low temp. of calcination (800-1000°). Points discussed include: the occurrence of Mg minerals, work of the Research Council on magnesite, the problem of hydration, calcination, magnesia as a flooring material, etc. Curves show the effect of heat treatment of plastic magnesia on initial set and on final set, and certain specifications and comparisons of plastics are tabulated. W. H. Boynton

**Crushing resistance. Linear deformation and cohesion according to the Jourdain test.** Vladimir Škola. *Chimie & Industrie Special No.*, 830 50(June, 1933).—Jourdain recommends that, in the crushing test of structural materials, a small rubber disk be placed between the sample and the crushing surface, the results thus obtained are lower than those by the usual procedure, but it is claimed there is better concordance between duplicate tests. Comparison of the 2 technics showed that the ratio between the results is not const., but depends on the properties of the material tested. Analysis of the accuracy of the 2 methods by the method of least squares showed that both the abs. variation and the relative variation were smaller by Jourdain's technic than by the usual procedure. A. Papineau-Couture

**The decomposition of mortars.** Ed. Marcotte. *Mém. compt. rend. soc. ing. civils France* 85, 129-43(1932); cf. C. A. 27, 2275.—A general discussion of the practical protection of mortars and concrete against the action of sea water and S-bearing waters. A. P.-C.

**Gypsum.** R. M. Santmyers. *Bur. Mines, Minerals Yearbook, 1932-33*, 617-28(1933).

**Methods for testing wood preservatives. I. Testing the corrosive effect of preservative solutions.** W. Krieg and H. Pfug. *Chem.-Ztg.* 57, 773-4(1933).—Iron plates, 2 × 20 × 80 mm. are immersed in 270 cc. of the soln. to be tested. After 10 days, loss in wt. is noted and

the appearance of the surface. The toxicity of the soln. before and after the test may be detd. II. Determining the leachability of preservatives from treated wood. *Ibid.* 794-5.—(1) Fifty g. pine saw-dust, treated with the preservative soln., after drying is successively washed with 50 cc. of  $H_2O$  10 times on a suction filter. The filtrates are analyzed separately. (2) A block of pine weighing 100 g. is impregnated with the preservative soln. under vacuum and after drying is split into match sticks. These are placed in a 1 l. flask, 600 cc.  $H_2O$  added and mechanically shaken 1, 2, 4, 6 and 8 hrs. After each shaking period the soln. is decanted and 600 cc. more  $H_2O$  is added. The resulting solns. are separately analyzed. (3) A series of wood blocks  $5 \times 2.5 \times 1.5$  cm. is impregnated as in (2). Ten dried blocks are placed in a 1 l. flask and 600 cc.  $H_2O$  is added. The flask is mechanically shaken for 30 days, 8 hrs. per day. The  $H_2O$  is changed at the beginning and end of each 8-hr. period. At the end of the test period the blocks are removed, dried at  $105^\circ$  and weighed. The flasks are then given a toxicity test by the "block nutrient agar method" of the Berlin Toxicity Conference 1930 (*C. A.* 26, 2205). A. K.

Hydrated Ca aluminates (Erculisse, Sapgir) 6. Repairs to reinforced concrete by the cement gun method (Pearson) 21. Chem. equipment from acid-resisting concrete (Bernatki) 1. Cold tar [for road surfacing] (Mallison) 21. App. for indicating the moisture content or consistency of concrete aggregates (U. S. pat. 1,930,831) 1.

Kieslinger, A.: Weathering of Stone Buildings. Its Cause and Prevention. Leipzig: F. Deuticke. Reviewed in *Mineralog. petrol. Mitt.* 44, 83-1 (1933).

Cements. "Straba" Strassenbaudarls A.-G. Brit. 391,122, June 22, 1933. Bituminous material is admixed with a hydraulic binding medium, e. g., cement, by atomizing or dispersing the 2 constituents and intermingling them. The bituminous material may also be thus admixed with  $Ca(OH)_2$ , tuff, furnace slag, etc., and later intermingled with dispersed cement.

Burning cement; roasting ores, etc. Fried. Krupp Grusonwerk A.-G. (Arno Andreas, inventor). Ger. 583,198, Aug. 31, 1933. Briquets or granules of the material are prevented from caking in the furnace by coating them with dust pptd. from the furnace gases.

Rotary kiln for burning cement raw materials. Povel T. Lindhard (to F. L. Smith & Co.). U. S. 1,929,953, Oct. 10. A kiln is described having a preliminary heating section comprising a perforated shell closed at its upper end and surrounded by a housing. Combustion gases from a calcining section of the kiln are delivered to the interior of the shell of the preliminary heating section. Various structural and operative details are described.

Rotary kiln for cement, etc. Fried. Krupp Grusonwerk A.-G. (Arno Andreas, inventor). Ger. 583,197, Aug. 30, 1933.

Pozzuolanic materials. Società anonima italiana per la produzione calce e cementi Di Segni. Brit. 391,518, June 29, 1933. The pozzuolanic activity of natural pozzuolanas and rocks of volcanic origin, e. g., volcanic ashes and tufts, basalts, diabases, trachytes, syenites, gabbros, Santorin earths, etc., is increased by heating to  $400-900^\circ$  and then chilling, e. g., by air, a mixt. of air and steam or a mixt. of air and  $HCl$ . The treated material may be mixed in powd. or granulated form with  $CaO$  or portland cement to form cements, mortars and concretes.

Paving material. Charles A. Mullen. U. S. 1,929,388, Oct. 3. A cold or but slightly warmed mineral aggregate is treated with a priming oil to coat the aggregate and facilitate subsequent admixtures. Bituminous cement is then added, followed by the addn. of another and dissimilar volatile oil as a temporary fluxing oil to soften the mixt. for transportation and laying so that heating is not required and the pavement will sustain traffic after laying and compaction.

Bituminous road-making compositions. Maschinenfabrik Komnick G. m. b. H. Brit. 205,288, July 13, 1933. The interstices between paving blocks are filled by a compn. prepd. by mixing sand with bitumen in a hot state. In an example the filling material comprises fine sand 100, bitumen 3.5 and  $Ca(OH)_2$  0.5-0.75 parts. The sand is perfectly dry and heated to  $150-200^\circ$  and mixed with liquid bitumen at the same temp., the  $Ca(OH)_2$  being added when the mixt. is cold. The blocks preferably comprise  $CaO$ -sandstone or a mixt. of  $CaO$  and  $SiO_2$  or silicic acid, molded and impregnated with bitumen, the proportion of bitumen being substantially higher than in the filling compn. The molded blocks are treated with steam under pressure for a short time to produce a thin skin of  $Ca$  hydrosilicate.

Bituminous compositions for making roads. Larvite (Foreign & Colonial Rights) Ltd. Ger. 583,238, Aug. 31, 1933. See Brit. 351,385 (*C. A.* 27, 390).

Bituminous emulsions for roads. Romag A.-G. für Rohmaterialien. Ger. 583,196, Aug. 31, 1933. Sulfite cellulose lye of about 16 B $\phi$ . and an acidity of 0.08-0.11 N, and tar or a soln. of bitumen in tar, are fed in approx. equal parts by wt. through a colloid mill or like emulsifying app. Fermented sulfite cellulose lye may be used, and about 0.2% of bentonite may be added to the lye before it is mixed with the tar.

Bituminous emulsions for use in making roads. Robert Tagg. Ger. 583,237, Sept. 4, 1933. A mixt. of tar and (or) petroleum bitumen with water glass and an org. solvent for tar and bitumen is agitated with hot milk of lime.

Calcining gypsum. Wilbur S. Randel and Manuel C. Dailey (to U. S. Gypsum Co.). U. S. 1,931,240, Oct. 17. Gypsum lumps of a diam. of one-eighth in. to 2 in. are agitated in a closed externally heated container for 2.5-5.0 hrs., evolved steam is removed to maintain a uniform gage pressure of 17-50 lb. per sq. in. in the container, the calcined product is ground so that 88% or more of it passes a 100-mesh screen, to obtain a product having a compressive strength of 3500-5000 lb. per sq. in. when set with water at pouring consistency. Cf. *C. A.* 27, 3052.

Apparatus (with a vertical cylinder and beater) for producing foam for light-weight gypsum products, etc. Bernard T. Ballard (to U. S. Gypsum Co.). U. S. 1,929,170, Oct. 10. Structural and mech. details.

Lining tubes. Veremigte Stahlwerke A.-G. Brit. 395,019, July 10, 1933. In lining tubes, etc., with a bituminous or similar material the cleaned tube is heated  $30-10^\circ$  above the working temp. of the bitumen which is then applied in a thin layer and baked. The tube is then cooled and a final thicker coating is formed centrifugally by injecting heated bitumen into the rotated tube.

Building materials. Michael Groskopf. Ger. 579,880, July 1, 1933. Addn. to 544,060 (*C. A.* 26, 3644) and 541,439 (*C. A.* 26, 2033). For sound- and heat-insulating purposes, use is made of bituminized material, prepd. as described in Ger. 544,660 or 541,439, in the form of a loose layer on which a solid layer united by a binder is superimposed.

Flat products formed from hydraulic cement and fibrous material. Lloyd R. Calkins (to Ruberoid Co.). U. S. 1,931,018, Oct. 17. Articles such as asbestos-cement shingles formed of hydraulic cement and fibers are pressed with a flexible membrane such as waxed paper interposed between opposed faces of the articles, in order to produce an irregular wavy surface.

Sound-absorbing material suitable for covering walls and ceilings. Ernest T. Hermann. U. S. 1,929,425, Oct. 10. A mineral aggregate such as pumice particles is mixed with a fusible ceramic binding material, in only sufficient quantity to coat the aggregate, the mixt. is formed into desired shape, and is heated to fuse the binding material. Various formulas are given.

Coating wood. H. Albert Hellmers. Ger. 584,253, Sept. 16, 1933. Freshly cut veneers are coated with an aq. mixt. contg. cellulose acetate, chrome alum, gelatin and glycerol.

## 21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND ALDEN H. EMERY

**Fuel problems of combustion engines.** G. D. Boerlage and J. J. Broeze. *Ingenieur* 48, W31 48(1933).—A lecture describing Diesel engine tests on the combustion qualities of different fuels, behavior of lubricating oils, etc.; the high-speed Diesel engine is especially discussed. The ignition qualities of Diesel oil are expressed (cf. C. A., 26, 4438) by the "cetane" index detd. by comparison of the oil with mixts. of cetene,  $C_{16}H_{34}$  and 1-methylnaphthalene. For normal Diesel oils this index (percentage  $C_{16}H_{34}$ ) is between 40 and 60; the index may be as low as 25 or as high as 70; rapid ignition is indicated by a high no. Many curves, drawings and tables are included and a detailed discussion of the operating characteristics of various types of high-speed Diesel engines.

B. J. C. van der Hoeven  
**The automatic regulation of combustion in producer furnaces.** Giulio Allata. *Gas u. Wasserfach* 76, 722 f(1933). More const. temps. are maintained in producer furnaces by using a controller to maintain the secondary air rate at a fixed ratio to the primary air. Advantages claimed are fuel economy and easier control of the furnace.

R. W. Ryan  
**Volumetric determination of the combustible constituents H - O/S and C in solid and liquid fuels.** Hellmann. *Feuerungstech.* 21, 136 8(1933).—Two rather similar pieces of app. are described in which the fuel is burned in a closed system with O and the contraction in vol. and  $CO_2$  produced are noted.

Ernest W. Thiele  
**Valuation of fuels for boiler and gas-producer plants.** E. Wesmann. *Arch. Eisenhüttenw.* 7, 329 32(1933). A method is developed which permits detg. the proper choice of fuel and a comparison of several kinds of fuel by exactly evaluating costs for all items entering into production and operating conditions of boiler plants and large gas-producer installations. The application of the formulas evolved is illustrated by several examples. M. H.

**Fuel comparisons for billet reheating furnaces.** G. W. Akerlow. *Gas Age-Record* 72, 103 6(1933).—Carefully controlled tests on costs of reheating steel billets gave the following results: (1) with a coal-fired furnace with a W. Va. coal of 14,125 B. t. u., at \$5.56 per ton, \$3.13 per ton of steel; (2) with oil of 28,876 B. t. u., of 19,300 B. t. u. per lb., costing at the burner 8.07¢ per gal., \$5.65 per ton; (3) with gas of 5,300 B. t. u. at 30¢ per M. cu. ft., \$5.13 per ton. To make gas fuel successful automatic control of temp. and gas feed must be maintained.

H. L. Olin  
**The use of alcohol as a motor fuel.** Adrian Corbett. *Petroleum Times* 30, 459(1933).—The economic and political aspects of the use of alc. as motor fuel in France, Germany, U. S. and other countries are discussed.

C. Wirth, III  
**The place of oil in the world of fuel.** John Cadman. *Gas J.* 204, 208 9, *Petroleum Times* 30, 501(1933). During the gasification of coal, energy equiv. to 20% of the total in the coal is consumed, but in the production of motor fuel by hydrogenation 60% is used up.

P. J. Wilson, Jr.  
**The problem of olive oils as fuels and lubricants.** S. Pachum. *Chimie & Industrie Special No.* 1078 9(June, 1933).—A criticism of recent attempts to use vegetable oils, and more particularly olive oil, as fuels for Diesel and similar engines and lubricants.

A. P. C.  
**How and why we burn cottonseed hulls.** V. Hoffman. *Power* 77, 462 3(1933). The hulls, analyze moisture 11.25, ash 2.52, volatile matter 68.81, fixed C 17.42%, and heating value 7,077 B. t. u. Operations are described.

Alden H. Emery  
**Production, utilization and conservation of coal in South Africa.** P. N. Latagan. *J. Chem. Met. Mining Soc. S. Africa* 34, 46 56(1933). General. A. H. E.

**Microscopic structure of Tzuhsien coal and its bearing on coking property.** C. C. Wang. *Contrib. Sin Yuan*

*Fuel Lab., Geol. Survey China No. 11; Bull. Geol. Soc. China* 12, 413-32(1933).—Coal from 8 seams was studied microscopically. In 5 seams there are abundant bands of fusain, xylain, xylovitrain and vitrain, in which fragmented or unfragmented cellular tissues are visible. Nearly all the Tzuhsien coals that are coking are composed essentially of wood or materials of woody origin. Analyses of 11 coals are given. Ash of > 10% or pyrite of > 1% are recognized microscopically in polished section.

Alden H. Emery  
**Graphical classification of Chinese coals.** K. Y. King. *Contrib. Sin Yuan Fuel Lab., Geol. Survey China No. 12; Bull. Geol. Survey China No. 21, 1-11(1933).*—The general features of 11 existing methods of coal classification are tabulated. A graphical method of coal classification is presented and applied to Chinese coals.

A. H. E.  
**The plastic range of coking coals in China.** K. Ping. *Contrib. Sin Yuan Fuel Lab., Geol. Survey China No. 10; Bull. Geol. Survey China No. 21, 45 56(1933).*—The plastic ranges of 17 Chinese coals were detd.; the Layng-Hathorne app. was used. The initial softening point (7 coals) was 342-433°, fusion point (15 coals) 364-457°, solidification point (16 coals) 410-690°, pressure of fusion point (14 coals) 38.5-133.0 mm., pressure at solidification point (14 coals) 82-346 mm., and swelling coeff. (17 coals) 0.90-2.72. Those coals showing greatest resistance to gas flow when plastic and those with the smallest range of plasticity give comparatively good cokes. Pressure difference/plastic range arranged the coals in order of their coking ability. P measured plastic properties of fractions of various sizes of the same coal and obtained different results for each size. He favors using 60-200-mesh coal for the test.

Alden H. Emery  
**A low-temperature carbonization assay of some Chinese bituminous coals.** C. C. Hsiao. *Contrib. Sin Yuan Fuel Lab., Geol. Survey China, No. 9; Bull. Geol. Survey China No. 21, 13-44(1933).*—Low-temp. carbonization tests were made on 16 Chinese coals with the Gray-King app. The coals analyzed moisture 0.10-2.00% and, on the moisture-free basis, volatile matter 21.25-37.60, fixed C 45.81-73.88, ash 4.31-20.59, S 0.57-5.47% and heating value 11,124-14,902 B. t. u. Yields of coke, oil, gas, liquor and  $NH_3$  and analyses of the coke and gas are given. High yields of oil are given by coals with high content of volatile matter. The well-known coking coals show rather low tar-oil yields. The younger the coal the greater is the tar yield. Low-temp. tars reflect the character of the coal more than high-temp. The gases are rich in satd. hydrocarbons and are relatively low in  $H_2$ ,  $CO$  and unsatd. hydrocarbons. Coals from Shunkengshan and Chiawang give a high oil yield and a strong coke.

Alden H. Emery  
**Recent developments in coal utilization.** A. C. Fieldner. *Bur. Mines, Minerals Yearbook 1932-33, 433-50(1933).*—Recent developments in combustion of coal, brown coal as fertilizer, plastics from brown coal, briquetting, seam. of bright and dull coal, high-temp. and low-temp. carbonization, hydrogenation and liquefaction of coal, and synthesis of chem. products from gases produced from coal or coke are described. Over 100 references.

Alden H. Emery  
**Uses of coal in the ceramic industry.** H. E. Noid. *Am. Inst. Mining Met. Engrs., Tech. Pub.* 509, 10 pp. (1933).—High-volatile coals are the most desirable solid fuels for kiln firing; low-volatile coals can be used. Producer gas is a desirable fuel and profitable in some larger plants. Natural gas is the greatest competitor of coal for kiln firing and largely has replaced coal for firing the finer wares. It cannot compete with coal in firing heavy clay products except in regions where cheap gas is available.

Alden H. Emery  
**Coal-washability curves. A discussion of efficiency formulas.** G. S. Scott. *Mineral Industries, Penna.*

*State Coll.* 2, No. 7, 8(1933); cf. *C. A.* 27, 3059.—The Drakeley and the France formulas are discussed.

Alden H. Emery

The inflammation of coal dusts: the effect of the nature of added incombustible dust. T. N. Mason and R. V. Wheeler. *Safety in Mines Research Board, Paper No. 79*, 13 pp.(1933).—Tests of 7 different incombustible dusts showed that their relative efficacies in preventing the propagation of coal-dust explosions were, in ascending order of effectiveness: shale (2 samples), fuller's earth, anhydrite limestone, pptd.  $\text{CaCO}_3$  and gypsum. Quantities were in the same ratios for both coals used, one of 21.7% volatile matter and one 36%. With the latter 67.1% of shale, 57.1% of limestone and 40% of gypsum were necessary to suppress inflammation.

A. H. E.

Mechanical separation of the constituents of coal. David Brownlie. *Steam Engr.* 3, 5-6, 44(1933).—Fusain and extraneous mineral matter can be sepd. from coal by froth flotation in 2 stages with starch or dextrin treated with acid. In the Lehmann process, coal is treated in a percussion mill and the 4 constituents, differing in friability, are roughly sepd. with air.

Alden H. Emery

The distillation of coal under very low pressures. V. Stone and M. W. Travers. *Chemistry & Industry* 1933, 686 7.—Distn. of coal under pressures of 0.01-0.001 mm. Hg and at a temp. of 350° yielded a brown pitch almost completely sol. in  $\text{C}_6\text{H}_6$  and a small residue sol. in abs. alc. Yields were almost identical with those obtained by Bunc with  $\text{C}_6\text{H}_6$  extn. under pressure and the possibility of identity of the 2 exts. is suggested.

H. L. Olin

Possible production of low ash and sulfur coal in Illinois as shown by float-and-sink tests. David R. Mitchell. *Univ. Ill. Eng. Expt. Sta., Bull.* No 258, 43 pp.(1933).—Float-and-sink data on Illinois coals from beds 1, 2, 5, 6 and 7 which have been compiled since 1931 are set forth to show the relative difficulties of producing clean products. In brief, No. 2 coals are amenable to treatment; No. 5 varies from simple to difficult; from No. 6 products of less than 6 8% of ash are possible; while No. 7 would prove somewhat difficult. X-ray technique has proved to be valuable in the study of ash in the coal structure.

Town gas and industrial recovery. R. D. Keillor. *Gas World* 99, No. 2568, *Ind. Gas Suppl.* 106-7(1933). Recent applications of gas in automobile factories, as a motor fuel, and for railways.

P. J. Wilson, Jr.

Possible improvements in gas and coke production. K. Hawthorn. *Gas World* 99, 349-51; *Gas J.* 204, 14 16(1933).

P. J. Wilson, Jr.

Gas-manufacturing plant for a small works. Wm. Scott. *Gas J.* 204, 217-18; *Gas World* 99, 376-7(1933).—A comparison of the operating and capital costs of horizontal retorts, vertical retorts, carburetted water gas, complete carburettation and a combination of horizontal retorts and carburetted water gas.

P. J. Wilson, Jr.

The Marienburg gas plant. Heidt. *Gas u. Wasserfach* 76, 720 2(1933).—A description of the Marienburg gas plant, with operating results. This plant consists of a bank of 5 Otto vertical ovens with a built-in producer.

R. W. Ryan

Centralized manufacture and distribution of gas in Belgium. Geo. Evetts. *Inst. Gas Engrs. Communication No. 71*, 56 pp.(1933); cf. *C. A.* 27, 3584.—The plant of the Cokeries du Brabant is described. It has a max. daily gas output of 116,400 therms, or a min. output of 52,800 therms with all ovens at work and a max. output of 1583 tons of coke (for sale), or 1075 tons at a min. with both batteries compounded. Data are given on horizontal ovens heated by coal gas (I) or by producer gas (II) and on continuous vertical chambers heated by coal gas (III) or by producer gas (IV). I and II yield 59.5 therms per ton of dry coal, III and IV 67.4 therms. I and II yield, per ton of coal, 11,650 cu. ft. of gas of 488 cal. heating value; III and IV give 16,600 cu. ft. of 470 cal. gas. I gives 6500 cu. ft. of surplus gas, II, 11,650 cu. ft., III 11,300 cu. ft. and IV 16,600 cu. ft. Net coke production was 1 875 tons, II 407 tons, III 473 tons and IV 266 tons. Benzene yield was 1 9.4 tons, II 4.85 tons, III 5.0 tons and IV 3.4 tons. Cost of gas per 1000 cu. ft. was I 6.0 d., II 7.25 d., III 6.75 d. and IV 7.75 d.

Alden H. Emery

A new installation of Glover-West verticals at Forli, Italy. C. Jori. *Gas J.* 204, 532(1933).—The capacity of the plant has been raised from a max. of 198,000 cu. ft. daily from the horizontal retorts to 318,000 cu. ft. by addn. of 8 Glover-West continuous vertical retorts.

P. J. Wilson, Jr.

Leakage in horizontal gas retorts. A. H. Lucas. *Gas World* 99, 421-5; *Gas J.* 204, No. 3676, *Institution of Gas Engineers Suppl.* 6-9(1933).—In order to det. the gas leakage from horizontal gas retorts, tests were made at New Wortley on fire clay retorts, each 20.5 ft. long and 22 in.  $\times$  16 in. oval D section, set 8 in a bed and fired with producer gas. The leakage was calcd. by use of the formula: Leakage in therms per ton of coal carbonized =  $797(a - c)/u(c - 13.2)$ , where  $a$  = percentage of  $\text{CO}_2$  in the theoretical combustion products (air-free, dry), and  $c$  = percentage of  $\text{CO}_2$  in the actual waste gases (air-free, dry). In tests on 9 beds, in which the working life of the retorts varied from 1570 to 2700 days and no retort had been scurfed within 20 days prior to the testing gas leakage losses varied between 2.7 and 0.7 therms per ton. The pressure in the middle line of the retort mouthpieces varied between 0.2 and 0.05 in. water during each test. Increase of this pressure to 1 in. increases the loss to the order of 15% of the gas. Studies were made of the losses due to the permeability of the retort material by pumping air into a sealed empty retort. The leakage was measured by the rate of delivery of the air and the pressure in the retort. The leakage results for a retort were found to approximate a straight-line function of pressure. Leakage was not influenced by the working life of the retort, nor by the position in the setting. After scurfing the leakage was greatly increased, and even after hot patching and spraying with a refractory slip it was extensive. Generally the leakage did not vary to any great extent beyond the first 6-10 days after scurfing. Although the wet spraying did not tighten the retorts, it did reduce the coke-discharging troubles from retorts with 1200 days of use to which it was applied.

P. J. Wilson, Jr.

The results of constructive policy as applied to a small gas undertaking. W. Clark Jackson. *Inst. Gas Engrs. Communication No. 52*, 33 pp.(1932).—Costs of caring for consumers' complaints due to naphthalene, rust and H<sub>2</sub>O condensation were reduced from 1988 (1920) to £211 (1930) and £117 (1932) by installation of a Dri-Gas and Naphthalene Washer. Costs of operating, including capital charges, were £174 (1930) and £166 (1932).

Alden H. Emery

Efficiency and economy in gas-works practice. H. C. Sims. *Gas World* 99, 446-8; *Gas J.* 204, 413-15(1933).—Small but important economies in the gas mfg. process may be effected by close attention to such points as coal quality, elimination of heat losses in the gas producer, performance of the charging machines on horizontal retorts, etc.

P. J. Wilson, Jr.

The design of town-gas-fired furnaces. F. L. Atkin.

*Gas World* 99, No. 2572, *Ind. Gas Suppl.* 112-18 (1933).—A. deals with furnaces operating at temps. of 600-1200°.

P. J. Wilson, Jr.

Investigating reactions taking place in gas generators. Rudolf Lehman. *Glashutte* 63, 270 (1933).—Investigations of reactions occurring in a generator with a revolving grate are described. The compn. of the gas present in different layers in the generator is given. M. V. K.

Applications of gas analysis to industrial problems. Morton Bernmann. *Gas Age-Record* 72, 211-14 (1933).—Numerous nomographic charts for solving practical problems are illustrated. H. L. Olin

Viscosity of natural gas. W. B. Berwald and T. W. Johnson. *Bur. Mines, Tech. Paper* 555, 34 pp. (1933).

By use of a simple app., the viscosity of gases is detd. easily by measuring the relationship between the friction factor and the Reynolds no. for flow of gas through circular tubing. A gas of known viscosity is used to det. the relationship for any tube. From this calibrated relationship and from the flow of gases of unknown viscosity through the tube, it is possible to calc. the viscosity of the latter within  $\pm 1.25\%$ . The smallest rates of flow (low Reynolds nos.) consistent with accuracy in volumetric measurement should be used. The observed viscosities of 25 natural gases of widely different chem. compns. at 60° F. and approx. atm. pressure were 0.00000646-0.00000866 lb. per sec.-ft., depending on the compn. Expts. at 40°, 60° and 80° F. show a viscosity increase of about 7% within this range, but varying somewhat with the chem. compn. Viscosities at 500 lbs. per sq. in. differ little from those at atm. pressure. Alden H. Emery

Limits of inflammability of natural gases. C. W. Jones and R. E. Kennedy. *Gas Age-Record* 72, 53 (1933). See C. A. 27, 4057. H. L. Olin

Thermal decomposition of the methane of Sarmasel (Rumania) natural gas. C. Candea and J. Kuhn. *Chimie et Industrie Special No.* 561-5 (June, 1933). In the presence of catalysts, decomn. was complete at 800-1000° according to equation  $\text{CH}_4 = \text{C} + 2\text{H}_2$ , without formation of intermediate products. The best results were obtained with the following catalyst:  $\text{Fe}_2\text{O}_3$ ,  $\text{CaCO}_3$ , 2,  $\text{NiO}$  1,  $\text{MnO}_2$  0.5, on an Fe film support. A. Papineau-Conture

The coordination of power relative to gas works. F. M. Birks. *Inst. Gas Engrs. Communication No.* 47, 40 pp. (1932).—The uses of power around a gas works, the most suitable forms for each, and generation in fuel fired or waste-heat boilers are described. Process steam is used for the manuf. of water gas, steaming retorts, steaming producers, production of benzene, manuf. of  $\text{NH}_4\text{SO}_4$ , heating gas prior to purification, gas drying, etc. The use of compressed air, hydraulic power, steam and electricity as a means of transmitting power is discussed and successful examples of each type around a gas plant are described. The uses of power in the works of the Gas Light & Coke Co. are described. Alden H. Emery

Investigation of nitric oxide in gas works. Vincent Porrazzo. *Gas Age-Record* 92, 123-4 (1933). The Schuitan method for NO is used in a modern gas lot in the study of the gum problem. A continuous and controlled flow of gas and  $\text{O}_2$  in the 2:1 ratio passes to a mixing bottle where they react for 15 min. The mixt. then passes to a soln. of *m*-ph. nylene diamine in AcOH where the Bismark brown is measured with the use of color standards. H. L. Olin

The application to the Battersea Power Station of researches into the elimination of noxious constituents from flue gases, and the treatment of resulting effluents. G. W. Hewson, S. L. Pearce, A. Pollitt and R. I. Rees. *Soc. Chem. Ind., Chem. Eng. Group*, 52nd Ann. Meeting, Preprint 1933, 35 pp.—A complete description is given of the development of a process for eliminating  $\text{SO}_2$  from the flue gas of a power station. The initial concn. of  $\text{SO}_2$  in the flue gas is between 0.02 and 0.05% by vol. as a result of burning coal contg. approx. 1% S. The gas is washed with aerated water in contact with  $\text{Fe}$  oxide. A second water washing is effected in a tower constructed of chemi-

cally inert material. A final scrubber employs an aerated alk. soln. contg. 0.25% lime. After passing through a baffled chamber to remove entrained moisture, the flue gas is exhausted to the atm. with 90% of the initial  $\text{SO}_2$  removed. The time of contact of the gas in the washer is about 30 secs. and about 20 tons of water and 10-12 lb. of lime or chalk are used per ton of coal burned. The effluent from the washers is aerated to oxidize sulfites. The completed installation is capable of treating the flue gas resulting from the burning of 133 tons of coal per hr. Also in *Engineering* 136, 459-61, 556-8 (1933).

I. W. T. Cummings

Removal of acid-sulfur compounds from combustion gases. David Brownlie. *Steam Engr.* 2, 517-19 (1933); cf. preceding abstr. and Johnstone (cf. C. A. 26, 3359).—A summary and discussion. Alden H. Emery

Making sulfur recovery from flue gases an economic process. Anon. *Steam Engr.* 2, 534-6 (1933).— $\text{SO}_2$  is removed from flue gases by washing with milk of lime with an efficiency of  $>90\%$ . About 1.5 tons of lime per ton of S and 200-300 gal. of  $\text{H}_2\text{O}$  per ton of coal burned contg. 2% S are used. Alden H. Emery

Gum deposits in gas-distribution systems. I. Liquid-phase gum. A. L. Ward, C. W. Jordan and W. H. Fulweiler. *Ind. Eng. Chem.* 25, 1224-34 (1933); cf. C. A. 27, 2557. —Gum-forming compds. must be removed from the gas systems. This may be done by several methods, namely, condensation (with water for cooling), supercondensation (refrigeration), compression or oil scrubbing. Data on oil scrubbing are presented rather fully. Reduction of O, the use of adsorbents,  $\text{H}_2\text{SO}_4$  and neg. catalysts are covered. M. C. Rogers

The upkeep of gas holders. R. J. Millbourne. *Gas J.* 204, 275-80, *Gas World* 99, 398-403 (1933).—M. discusses factors in the design to handle the imposed loads, corrosion and painting. P. J. Wilson, Jr.

Repairs to reinforced concrete—by cement gun method. Geo. C. Pearson. *Gas J.* 204, 343-53; *Gas World* 99, 469-77 (1933).—Repairs to gas plant structures and protection against corrosive atm. by guniting are described. P. J. Wilson, Jr.

Corrosion from products of combustion. 33rd Report of the Joint Research Committee. Institution of Gas Engineers and Leeds University. *Gas J.* 204, No. 3676, *Institution of Gas Engineers Suppl.* 2, 1 (1933).—The preliminary investigations indicate that  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_3$  formed by combustion of S compds. in the gas are the main cause of corrosion of gas appliances; but the problem is complicated by the presence of oxides of N and water vapor condensed to a variable extent in different types of appliances. P. J. Wilson, Jr.

Third Report of the Liquor Effluents and Ammonia Subcommittee. Institution of Gas Engineers. *Gas World* 99, 425-7; *Gas J.* 204, No. 3676, *Institution of Gas Engineers Suppl.* 4, 5 (1933). Expts. on the biochem. oxidation of gas works liquor along with sewage in sectional and non-sectional bacteria beds, and in a lab. activated sludge app. have shown that although all the substances present could be destroyed completely, the individual compds. are not all of the same importance. The removal of phenol alone would appear to be of doubtful benefit. It would seem that a particularly suitable spent liquor would be produced from a crude liquor originating in gas which, while still above the dew point, is passed through an efficient tar precipitator, and is kept free from O until it enters the purifiers. This liquor will be free from higher tar acids, thiocyanates and thiosulfates. Tests on the removal of  $\text{NH}_3$  and phenols from ammoniacal liquors by distn. show that  $\text{NH}_3$  is 6.2 times as volatile as phenol. Phenol is less volatile than the cresols. The presence of  $\text{NH}_3$  in the liquor retards the distn. of phenol. A process for recovering  $\text{NH}_4\text{HCO}_3$  from crude vertical retort gas by concn. of all the  $\text{NH}_3$  in a fraction of the gas contg. sufficient  $\text{CO}_2$  to combine with it in mol. proportions is outlined. The  $\text{NH}_3$  and  $\text{CO}_2$  are absorbed continuously in a bath of  $\text{NH}_4\text{HCO}_3$  from which the salt crystallizes. Losses of benzene from the Partington benzene process dephenolizing

plant have been reduced by washing all the vapors leaving the plant in a scrubber fed with gas liquor.

P. J. Wilson, Jr.

**Liquid purification with otherwise waste ammonia.** John D. Price. *Gas World* 99, 342; *Gas J.* 204, 142 3 (1933).—At Montreal  $\text{NH}_3$  and  $\text{H}_2\text{S}$  are partially removed from coke-oven gas by water circulated in a closed system; first, through the final cooler in which absorption occurs; second, through the producer gas cooler in which the  $\text{NH}_3$  and  $\text{H}_2\text{S}$  are taken up from the water by the producer gas; and last, through a set of cooling coils. The cooled water is then returned to the final cooler. The  $\text{NH}_3$  is reduced from 300–350 grains per 100 cu. ft. to 120–150, and the  $\text{H}_2\text{S}$  from 250 to 90 grains. The  $\text{NH}_3$  in a mixed gas contg. 0.2% coke-oven gas is further reduced to 20–40 grains entering the oxide boxes by an addnl. water wash. This water is distd., and the  $\text{NH}_3$  added to the gas entering the primary cooler.

P. J. Wilson, Jr.

**The removal of phenol from gas-house water.** I and II Otto Krebs. *Chem.-Ztg.* 57, 721 3, 743–4 (1933).—A review of phenol scrubbing methods with diagrams of app. and flow.

H. L. Olin

**Modern methods of benzene refining.** The use of inhibitors to prevent gum formation. W. H. Hoffert and G. Claxton. *Gas u. Wasserfach* 76, 704 10 (1933); cf. *C. A.* 27, 4653. —Previous methods of stabilizing motor benzene resulted in excessive loss of unsatd. hydrocarbons. The most valuable inhibitors for preventing gum formation in storage are phenols and aminophenols. The effect of inhibitor addn. can be detd. both by finding the small amt. of gum formed during the inductive period as well as the length of this period before appreciable amts. of gum are formed in the oxidation test for gum-forming tendency. While 0.01% com. cresol contg. at least 60% *o*- and *p*-cresol is sufficient for many benzenes, 0.03–0.05% is added for safety. Although this inhibitor is suitable for many benzenes, some give better results with  $\alpha$ -naphthol, *p*-methylaniline, *p*-benzylaminophenol and pyrogallol. Each inhibitor has a definite range of concn. over which it gives the min. amt. of gum during the inhibition period. Inhibitors must be volatile and must not form non-volatile compds. Crude benzene may contain  $\text{SO}_2$ , which prevents inhibitor action, or substances such as thiophenol which reduce their action. These substances as well as inhibitors present in the crude benzene are removed by treatment with dil. alkali soln., followed by washing. Badly colored benzenes with a bad odor may be given a preliminary treatment with 2% by vol. of 75–80% of  $\text{H}_2\text{SO}_4$  before the alkali treatment. Odor alone may be removed by 3.5% by vol. of 25–40%  $\text{H}_2\text{SO}_4$ . After the alkali treatment and water washing the benzene is distd. and the inhibitor added during distn. to prevent gum formation. Treated benzenes ordinarily form about 1–3 mg. gum during storage up to 18 months and rarely as much as 5 mg. per 100 cc. Advantages of this process are low reagent cost, no appreciable acid tar, greater antiknock power of benzene, higher yields and adaptability to continuous operation.

R. W. Ryan

**Physicochemical conditions in the performance of distillation installation for production of crude benzene.** S. Krolevitz. *Khimstrof* 5, 2363 71 (1933).—Tabular presentations and discussion are given of the phys. and chem. conditions observed in the distn. for recovery of crude benzene extd. from coking gases. Chas. Blanc

**Sulfur elimination from flue gases.** David Brownlie. *Steam Engr.* 3, 22 (1933).—Addition to *C. A.* 25, 5750.

Alden H. Emery

**The removal of sulfur from metallurgical coke.** III. Coking coal with the addition of inorganic substances.

I. V. Shimanenkov and A. N. Blazhennova. *J. Chem. Ind. (Moscow)* 1933, No. 6, 31–6; cf. *C. A.* 26, 3051.

The addn. of  $\text{NaCl}$  to coal before coking removes more S from the product than any other substance studied.  $\text{MgO}$  and  $\text{MgCO}_3$  remove somewhat less S than  $\text{NaCl}$ , but the final S content is still below that of untreated coke.  $\text{MgCO}_3$  also increases the yield of gas formed in the process. Fe ore and  $\text{CaCO}_3$  do not greatly alter the S content,

and Fe ore lowers the yield of coke.  $\text{CaO}$  binds most of the S as  $\text{CaS}$ , lowers the yield of coke and increases the yield of gas. Dolomite increases the content of org. S in the coke and decreases the yield of gas. H. M. L.

**The treatment and distillation of tar by hot crude gases.** Alfred L. Holton. *Gas J.* 204, 331–41; *Gas World* 99, 435–45 (1933).—Tars which meet in all particulars the Brit. Standard Road Tar Specifications are successfully produced by contacting vertical retort tar with the hot gases from a Trefois producer in a vertical main, and by circulating it through the collecting and offtake mains on several batteries of vertical retorts. The mains are insulated as completely as possible, and are so operated that the gas temp. at the point of initial contact with the tar is sufficiently high to eliminate all oils not required in the road tar specified. No water is circulated in the mains. The heavy tarry deposits ordinarily encountered in the foul mains of retort houses have not been found. The process is simple. Operating results and design for tar sprays are given. The results of an expt. in which 12 tons of vertical retort tar were cracked by the process of the Firma Carl Still are described.

P. J. Wilson, Jr.

**Cold tar.** H. Mallison. *Teer u. Bitumen* 31, 273–6 (1933).—The properties of tar for use in volatile solvents for road surfacing and their detn. are discussed.

F. W. Jung

**Coke Oven Manager's Association. Presidential address.** W. E. Mordecai. *Gas World* 99, No. 2570, *Coking Sect.* 113 14; *Gas J.* 204, 263–4 (1933).—A discussion of the relative values of coke properties to different consumers leads to a plea for more research.

P. J. Wilson, Jr.

**The coke-oven plant at Beckton Gas Works.** R. W. Hunter. *Inst. Gas Engrs. Communication* No. 68, 54 pp (1933); cf. *C. A.* 27, 3586. —The coke ovens, the producer-gas plant, and the tar and  $\text{NH}_3$  recovery plant at Beckton Gas Works are described. Detailed costs and yields are given for continuous verticals, intermittent verticals, coke ovens and horizontal. A. H. Emery

**Recent developments in coking practice.** Heinrich Koppers. *Gas J.* 204, 267 72 (1933).—*Carbolux* is a coke produced by carbonizing coal between  $680^\circ$  and  $720^\circ$ . Its reactivity approaches that of wood charcoal, and is practically the same for any kind of coal. The burning qualities, high crushing strength, low friability and other properties render *Carbolux* an excellent domestic fuel. Tests made in a full-scale exptl. oven have shown that by addn. of a suitable filler (low-temp. coke) practically all caking coals may be converted by moderate temps. into a large-sized, solid fuel, and frothing and swelling of the coal in the oven are prevented. The investigation has also shown that an oven width of 11.8–13.8 in. is suitable for the carbonization of most coals at medium temps. and the production of a large-sized high-temp. coke. For *Carbolux* alone 11.8 in. and less have advantages. *Carbolux* is produced at Bruay, France, in 50 Koppers hairpin combination ovens, each with a capacity of 120 cu. ft. of coal, the designs of which are fundamentally the same as those for high temps. In these ovens the charge is homogeneously fused with no center parting, and the pieces broken up by the coke guide often have a surface area each of 10.7 sq. ft. The filler is produced in rotary, horizontal retorts, and then thoroughly mixed with the rest of the coal. The mixt. is so proportioned that shrinkage amounts to 1.5–2 cm. on each side of the charge. The coke yield is 7–9% higher than by high-temp. carbonization of the same coal. An oven of narrow width and correspondingly small capacity, even with lower carbonizing temps., shows no reduction in daily capacity as compared with a large oven at high temps. Since the capital cost for a plant with narrow ovens is less than that for a plant with wide ovens, the cost of production of coke cannot be higher.

P. J. Wilson, Jr.

**The preparation of coke for the London market.** F. M. Birks. *Gas J.* 204, 399 402 (1933).—The coke is quenched, crushed, screened and finally cleaned in an effort to provide a smokeless fuel of proper size and quality for the different uses. If the larger grades the denser cokes from coke ovens and intermittent chambers are sized somewhat

smaller than the lighter cokes from vertical continuous and horizontal retorts.

P. J. Wilson, Jr.

**Studies on coke and charcoal. XV. Preparation of selectively de-ashed carbon.** Y. Oshima, Y. Fukuda and S. Takashima. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 545-6(1933); cf. *C. A.* 27, 3804.—Samples of coke, charcoal, sugar C and C black were treated, for the purpose of selective removal of ash, with HCl, H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, HF and a mixt. of HCl and HF. It was found that gas coke and charcoal differ markedly in HF-sol. ash content and that in the charcoal the percentage decrease of ash due to the HF-HCl treatment is almost identical with the sum of those due to the resp. individual treatments with HF and HCl. The gas coke did not show such a differentiation but a certain amt. of ash was sol. in both acids. Exptl. results for the various acid treatments are presented. C was oxidized only in the treatments with HNO<sub>3</sub>.

Karl Kammermeyer

**The influence of pressure-hydrogenation upon the coking constituents of coals.** I. J. B. Blom. *J. Chem. Met. Mining Soc. S. Africa* 34, 1-44(1931). Four non-coking coals were hydrogenated at 380-395° for 5 hrs. The resulting shiny pitch-like substance was strongly coking. Heating alone or under pressure is ineffective. Hydrogenation forms large units. of benzene-sol. substances resembling the benzene pressure exts. of bituminous coal. Fraction II added to high-temp. coke is binding, fractions III and IV yield strong coherent cokes. At 80° benzene removes oily as well as solid material from the hydrogenated coal, leaving residues with coking properties. At 270° all coking elements are extd.; the solid fractions form 79-91% of the ext. With increasing maturity of coals hydrogenated the ext. at 80° falls relative to the portion extd. at 270°. The increase in the benzene-sol. portion in coals hydrogenated above 380° is due to solid rather than oily fractions. Hydrogenation is more sensitive to increase in temp. than in pressure. After hydrogenation and complete extn. with benzene, further hydrogenation produces more benzene-sol. material, but it eventually reaches an end point. Hydrogenation research is reviewed. Seventy references. Alden H. Emery

**Plastic properties of coking coals.** Joseph D. Davis, P. W. Jung, Bernard Juchner and D. A. Wallace. *Ind. Eng. Chem.* 25, 1269-74(1933).—Plastic penet. tests applied to 22 American coals covering the range in rank of those suitable for coke making have been correlated with the coking properties of the same coals carbonized by the Bureau of Mines test methods. The tests are: expansion and contraction by the Damm-Agde method, resistance to the passage of N by the Layng-Hathorne method, the max. stickiness using the plastometer, and the agglutinating power by the Marshall-Bird method. The quality of the coke is measured by the av. of the shatter index on 1.5 in. and the tumbler index on 1 in. The Damm-Agde test is the only one that does not show a rough proportionality with the strength of the coke; the agglutinating test is the best measure of this property. The apparent sp. grs. and the porosities of the cokes are shown not to vary much for coals of medium and high rank.

P. J. Wilson, Jr.

**The combustible properties of coke.** H. E. Blayden and H. L. Riley. *Gas World* 99, No. 2570, *Coking Sect.*, 116-21(1933).—An app. is employed for comparing the combustible properties of coke by measuring under standard conditions the min. air current in which coke of 10-20 J. M. M. grading will continue to burn, and the relative rates of coke consumption. The results were readily reproducible. Correlation of the results from preliminary tests by this method with known performance of cokes in domestic appliances and in cupolas indicates that the method is capable of differentiating cokes on the basis of differences in their combustible properties.

P. J. Wilson, Jr.

**Behavior of coke in the open grate.** E. I. Lloyd, F. Bell and H. J. Hodsmann. *Gas J.* 204, No. 3676, *Institution of Gas Engineers Suppl.*, 12-16(1933).—The behavior of cokes when consumed in the open grate has been examd. and correlated with the properties of the cokes

capable of measurement in the lab., i. e., reactivity to CO<sub>2</sub> and to O, ignition temp., ash content and bulk density. The ignitability of a no. of different cokes was increased by the application of a skin of coal (tar is the adhesive), the effect being most pronounced with coke made in continuous vertical retorts. The treated coke emits some smoke, but the quantity can only be a fraction of that from coal.

P. J. Wilson, Jr.

**Fuel economy in the glass industry (Brownlie) 19.** Waterless gasholder accident at Neunkirchen (Anon.) 24. Use of coal as a fertilizer (Kissel) 15. Sepp. mixed materials such as those of "run-of-mine" coal (U. S. pat. 1,931,008) 1. App. for injecting liquid material into gas streams (U. S. pat. 1,930,848) 1.

**Fuel briquets.** Walter E. Trent (to Trent Process Corp.). U. S. 1,929,800, Oct. 10. Pulverized bituminous coking coal is mixed with heavy hydrocarbon oil and the mixt. is heated sufficiently to vaporize a substantial portion of the oil and to reduce the unvaporized portion to an asphaltic condition. The coal particles thus are coated with asphaltic material and this coated material then is mixed with a substantially greater amt. of low volatile carbonaceous solids such as coal or coke and the mixt. is formed into briquets.

**Fuel pastes.** James S. B. Fleming and Imperial Chemical Industries Ltd. Brit. 394,696, June 30, 1933. Fuels in paste or like form adapted to produce heat for relatively short periods are obtained by incorporating with a soln. of nitrocellulose in EtOH or MeOH a nitrocellulose that is insol. in the alc. Citric acid or other agent preventing gelation, small amts. of other combustible liquids not causing soln. of the insol. nitrocellulose and coloring materials may be added.

**Solid fuel.** Hugh Archbald. U. S. 1,930,377, Oct. 10. A mixt. is formed of cokable material such as anthracitic, bituminous and tarry materials so proportioned as to coke without substantial deformation and to retain as planes of facile fracture the faces where pressure has been applied; this mixt. is extruded in the form of a thick-walled tube having a small bore, without substantial preheating, into a coking zone so heated that the surface of the extruded material is subjected immediately to a temp. above the range of sticking temps. of coking coals, and coking is effected while the material is still in the form of a tube. App. is described.

**Apparatus for testing fuels and other combustible liquids to ascertain the temperatures at which they ignite spontaneously in heated air and the intervals at various temperatures between contact with and ignition or explosion in the heated air.** William Hehnore. Brit. 394,736, July 6, 1933.

**Low-temperature carbonization of carbonaceous materials.** Mathias Pier and Karl Winkler (to Standard-I. G. Co.). U. S. 1,929,649, Oct. 10. For sepp. the contained oils from semi-liquid oil-bearing residues obtained by destructive hydrogenation of carbonaceous materials such as coal, the oil-bearing residues are made up into a paste with finely divided solid carbonizable material such as lignite dust and the mixt. is carbonized at a low temp. in the presence of a counterflow of hot inert scavenging gas. App. is described.

**Destructive hydrogenation of carbonaceous materials.** Hein I. Waterman (to N.-V. de Bataafsche Petroleum Maatschappij). U. S. 1,929,528, Oct. 10. In the destructive hydrogenation of materials such as brown coal, a catalyst is used comprising a mixt. contg. Mo and an activated mass derived from an alk. Fe oxide-contg. material obtained from the conversion of bauxite to Al oxide by wet treatment. Cf. *C. A.* 27, 4379.

**Apparatus for proportional mixing of coal and binder for briquets, etc.** Emory B. Jones and Jesse L. Knight (to Winding Gulf Collieries). U. S. 1,929,663, Oct. 10. Various structural, mech. and operative details are described.

**Apparatus for washing coal or other minerals.** George Norton. U. S. 1,931,390, Oct. 17.

- Compressing coal before coking.** C. Otto & Co. G. m. b. H. Ger. 584,309, Sept. 19, 1933. Details are given of a method of procedure in which the pressure applied varies inversely with the water content of the coal. Cf. C. A. 27, 2561.
- Vertical retort suitable for distilling coal, shale, lignite, etc.** Ernst L. Schultz. U. S. 1,931,417, Oct. 17. Various structural and mech. details are described of an app. comprising a heating cylinder and 2 superposed surrounding concentric rotatable cylinders spaced apart from the heating cylinder.
- By-product recovery in coal distillation.** Laurence R. Forrest (to Barrett Co.). U. S. 1,930,124, Oct. 10. Parts of coal-distn. gases are cooled and tar is sep'd. from them. The resulting gases are cleaned to sep. tar and pitch particles from them. Tar is distd. by bringing it into intimate contact with another part of the hot coal-distn. gases, the resulting gases are cleaned to sep. suspended tar and pitch particles from them, and the 2 portions of cleaned gases are combined at a temp. above the dew point for the gases for water and then are passed through an ammonia saturator at a temp. above the dew point of water. App. is described.
- Spiral baffle apparatus for purifying steam by removal of condensed water and foreign matter.** Wilson L. McLaughlin, Herold L. McLaughlin and Virg. Ballou. U. S. 1,931,135, Oct. 17. U. S. 1,931,136 relates to structural features of a steam condenser and water pre-heater.
- Steam condenser.** Henry E. Byer. U. S. 1,929,403, Oct. 10.
- Apparatus for superheating steam.** Heinrich Peperkorn and Otto H. Hartmann (to The Superheater Co.). U. S. 1,929,514, Oct. 10. Structural features.
- Steam desuperheaters.** The Superheater Co. Ltd. and John E. Wood. Brit. 394,417, June 29, 1933.
- Apparatus for desuperheating steam, etc.** Dagobert W. Rudolph (to The Superheater Co.). U. S. 1,929,520, Oct. 10. Structural and operative details are described.
- Combustible gas.** Wm. W. Odell (to Columbia Engineering & Management Corp.). U. S. 1,930,442, Oct. 10. A mixt. of steam and hydrocarbon gas comprising chiefly  $C_2H_4$  and  $C_2H_6$  is introduced into a highly heated fuel bed to produce a gas comprising essentially H and CO in the ratio of 2 to 3, resp., and the resulting gas is enriched by at least partially reforming in it, in a chamber contg. refractory material, hydrocarbon material of normally liquid character. App. is described. U. S. 1,930,443 relates to the manuf. of gas by air-blasting an ignited fuel bed to bring it to incandescence, separately introducing a hydrocarbon material into a stream of superheated steam and thoroughly mixing and heating the steam and hydrocarbon material to above  $540^\circ$ , introducing the heated gaseous product into the incandescent fuel bed from above and removing the resulting gas from beneath. The gas generated contains 2.0 to 3.5 times as much H as CO and is substantially free from suspended carbon resulting from pyrolysis of the hydrocarbon material. App. is described.
- Purifying gases such as coal gas.** Thyssen'sche Gas- und Wasserwerke G. m. b. H. Ger. 583,417, Sept. 2, 1933. Addn. to 457,264 and 482,880 (C. A. 24, 445). The bulk of the tar is removed in known manner, and the gas is then cooled to below  $15^\circ$ , e. g., to  $-10^\circ$ , in two stages.  $C_{10}H_8$  is removed in the first stage, and most of the  $NH_3$  in the second stage. The gas may be treated directly in the first stage with an oil which dissolves  $C_{10}H_8$ , and in the second stage with cooled  $NH_3$  liquor. The gas then may be treated, while still at a low temp., with a dehydrating liquid.
- Purifying coal gas.** Gewerkschaft Mathias Stinnes. Ger. 584,048, Sept. 14, 1933. Coal gas, which has been purified and cooled in the usual way, is freed from residual  $C_{10}H_8$  by passing it at a temp. above  $40^\circ$  and at atm. or raised pressure through an oil which dissolves  $C_{10}H_8$ . Oil vapor is then removed from the gas by cooling.
- Coal-distillation gases.** Harald Kemmer. Ger. 584,041. Sept. 13, 1933. The sensible heat of the combustion products from gas works, coke ovens and like plant is used to operate an absorption refrigerating machine, and the low temp. attained is utilized in purifying the coal-distn. gases.
- Horizontal retort system for producing gas and coke.** Hermann Bröcker. Ger. 583,113, Aug. 20, 1933.
- Step-grate gas producers.** Woodall-Duckham (1920) Ltd. and James W. Reber. Brit. 391,737, July 6, 1933.
- Heat-regenerating system for water-gas producers using pulverulent or liquid fuel.** Gas- und Teer G. m. b. H. Ger. 583,415, Sept. 18, 1933.
- Gas holders.** Shell-Mex & B. P. Ltd. and Edwin H. P. Young. Brit. 395,067, July 13, 1933.
- Dry gas holders.** Maschinenfabrik Augsburg-Nürnberg A.-G. Brit. 394,270, June 22, 1933.
- Waterless gas holders.** (Firm of) Aug. Klonne. Brit. 393,887, June 15, 1933.
- Means for maintaining horizontal the floating disk of a gas holder.** Edward L. Pease. Brit. 393,285, May 30, 1933.
- Desulfurizing gases and vapors.** I. G. Farbenind. A.-G. (Hans Bahr, inventor). Ger. 583,387, Sept. 2, 1933. Gas or vapor mixts. contg. H<sub>2</sub>S and org. compds. of S are passed at  $300-600^\circ$  over catalysts such as Sn, Pb, Cu, Zn or Cr, or their oxides or salts, whereby the org. S compds. are reduced to H<sub>2</sub>S. The H<sub>2</sub>S formed, and that originally present, are then catalytically oxidized in known manner at a lower temp., e. g.,  $200-450^\circ$ . Details are given of the treatment of coal gas. Cf. C. A. 27, 2564.
- Removing hydrogen sulfide from natural or other gases.** Grover M. Ford and Otto H. Schenwald. U. S. 1,930,875, Oct. 17. The gas is contacted with an aq. soln. of NaCl contg. dissolved  $Ca(OH)_2$  under pressure at least as great as that of the incoming gas; spent treating liquid is withdrawn and steam is passed through it in an open receptacle; the resulting liquid is cooled in heat-exchange relation to water at atm. temps. and the cooled liquid is pumped into fresh aq. NaCl soln. contg. dissolved  $Ca(OH)_2$  preparatory to beginning another cycle of operation. The gas contact is effected countercurrentwise. App. is described.
- Removing sulfur oxides from flue gases containing free oxygen.** Henry J. Hodsman and Alan Taylor (to W. C. Holmes and Co. Ltd.). U. S. 1,931,408, Oct. 17. The gases are passed continuously through a chamber in which they are subjected to a co-current contact with an aq. soln. contg.  $NH_3$ .
- Extracting phenols, etc., from oils containing them.** Ralph H. McKee. U. S. 1,929,438, Oct. 10. Oils such as "tar oils" are treated with a relatively strong aq. soln. of an org. acid salt of a base-forming metal such as Na cymenesulfonate in order to ext. constituents such as phenols and the soln. is sep'd., dild. and treated for recovery of the extd. substances.
- Removing carbon oxides from gases.** I. G. Farbenind. A.-G. (Georg Schiller, inventor). Ger. 583,241, Aug. 31, 1933. CO and  $CO_2$  are removed in one operation by washing the gases at atm. or raised pressure with aq. liquids contg. a cuprous compd. and a difficultly volatile amine capable of combining with  $CO_2$ , preferably  $N(C_2H_5OH)_3$ .
- Tar distillation.** Stuart P. Miller (to Barrett Co.). U. S. 1,930,130, Oct. 10. Hot fresh coal-carbonization gases from various coal-carbonization units are divided into 2 parts. One part is cleaned at a high temp. to remove solid and liquid impurities entrained in the gases, and the matter thus removed is distd. in the other portion of the coal-carbonization gases while they are still hot, and these gases are cleaned at a high temp. to remove entrained solid and liquid particles, and the cleaned gases are cooled to sep. clean oils. An arrangement of app. is described.
- Coking agglomerates of zinciferous and carbonaceous reducing materials.** Earl H. Bunce (to New Jersey Zinc Co.). U. S. 1,929,408, Oct. 10. See Brit. 344,570 (C. A. 27, 829).
- Coke-oven operation.** Carl Still G. m. b. H. Ger.

584,067, Sept. 14, 1933. Details are given of a method of forming channels in the compressed coal mass in the oven chambers. Cf. C. A. 27, 1150.  
 Regenerative vertical-chamber coke oven. C. Otto & Co. G. m. b. H. Ger. 594,055, Sept. 14, 1933. Addn. to 460,752 (C. A. 23, 1535).  
 Roller mill for breaking coke. Roy W. Green and Aldridge & Ranken, Ltd. Brit. 394,430, June 29, 1933.

## 22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. PARAGHIER

The world's petroleum resources. R. Brunschwig. *Mem. compl. rend. soc. ing. civils France* 85, 141-94 (1932). A. Papineau-Couture.

The nature of Roumanian petroleum. Emil Severin. *Petroleum Z.* 29, No. 28, 13 (1933).—Analytical data for petroleum from various Roumanian fields are given, including C, H, S, N and O contents, and the percentage of light and heavy naphtha, kerosene and gas oil. The oil contains 1-4% of light aromatic hydrocarbons.

Chemical composition of petroleum. I. M. Levine and R. A. Virabyantz. *Erdol u. Teer* 9, 170-2, 187-9, 202-3, 220-2 (1933); cf. C. A. 23, 3400.—The aromatic and unsatd. hydrocarbons, naphthenes and methane hydrocarbons of 8 European oils have been sepd., detd. and examd. Data are tabulated to show that the hydrocarbons comprise these 4 classes and that 6 types of petroleum are defined by their chem. compn., e. g., (1) methane; (2) naphthene; (3) methane-naphthene; (4) aromatic; (5) methane-naphthene-aromatic; and (6) naphthene-aromatic petroleum. Types (1), (2) and (3) are characterized by small proportions of polycyclic compds. and by long side chains. In Type (5) there are more polycyclic aromatic compds. and naphthenes. In Type (6) the ring structures are most complicated and the side chains shortest. It yields the best lubricants inasmuch as only the polycyclic naphthenes and aromatic compds. lubricate, the tricyclic being more viscous than the bicyclic. Aromatic compds. are more viscous than naphthenes but resist oxidation less. F. W. Jung.

The chemical composition of petroleum. I. The chemical composition of petroleum gases. A. N. Sakhanov, A. I. Doladugin and I. I. Lapkin. *Gosudarstvennoe Nauch.-Tekh. Izdatel'stvo Moscow-Petrograd* 1931, 3-17; cf. C. A. 27, 1151. Various methods for analyzing gases are described. Grozny natural gases are characterized by a high content of casing-head gasoline (25-30% by vol.) due to the high temp. of the petroleum in the well, 75-80°. The compn. of gases, depending on the depth (sand layer), is (av.):  $\text{CH}_4$  31.6-51.0,  $\text{C}_2\text{H}_6$  7.4-12.8,  $\text{C}_3\text{H}_8$  11.0-21.7, iso- $\text{C}_4\text{H}_{10}$  7.2-11.5,  $\text{C}_4\text{H}_{10}$  6.0-9.5,  $\text{C}_5\text{H}_{12}$  and higher 7.4-13.4% and sp. gr. 1.207-1.111. The detns. were carried out with gases freed from air and gasoline. Gas used in gasoline compressing plants from the New Grozny field contains  $\text{CH}_4$  44-8,  $\text{C}_2\text{H}_6$  7.5-8,  $\text{C}_3\text{H}_8$  14-17,  $\text{C}_4\text{H}_{10}$  8-9, iso- $\text{C}_4\text{H}_{10}$  7-9 and  $\text{C}_5\text{H}_{12}$  and higher homologs 12.5-15%. The Old Grozny district has 2 types of gas. (1) is similar to gas from New Grozny fields and (2) contains  $\text{CH}_4$  70-75,  $\text{C}_2\text{H}_6$  6-7,  $\text{C}_3\text{H}_8$  8-10,  $\text{C}_4\text{H}_{10}$  5-7 and  $\text{C}_5\text{H}_{12}$  and higher homologs 4-5%. Gases from the Matkop oil field C horizon contain  $\text{CH}_4$  85,  $\text{C}_2\text{H}_6$  3.5,  $\text{C}_3\text{H}_8$  3.8,  $\text{C}_4\text{H}_{10}$  and higher homologs 3.3 and  $\text{CO}_2$  5; those from the F horizon contain:  $\text{CH}_4$  7-10,  $\text{C}_2\text{H}_6$  17-25,  $\text{C}_3\text{H}_8$  35-40,  $\text{C}_4\text{H}_{10}$  18-19 and  $\text{C}_5\text{H}_{12}$  and higher homologs 7-8%. The amt. of casing-head gasoline found in gas from the New Grozny fields is 1050-1100 g. per cu. m., Old Grozny fields (a) 350 g. per cu. m., and (b) 200 g. per cu. m. and that from the Matkop gas is insignificant. Properties of some stabilized gasolines are given. II. Method for the determination of the chemical composition of straight-run gasolines and the determination of aromatic compounds. A. N. Sakhanov, M. D. Tilicheev and A. I. Dumskaya. *Ibid.* 18-79.—A large no. of synthetic mixts., individual compds. and fractions from petroleum were investigated. It is concluded that the detn. of "benzene," "toluene" and "xylene" fractions can be carried out by the aniline pt., nitrobenzene, refractometric and sp. gr. methods. The

refractometric method is given preference because of its simplicity and the small amt. of substance needed. The detn. of aromatic compds. in the 150-200° fraction is made by the aniline or nitrobenzene method because of the smaller influence of the varying structure of aromatic compds. in this fraction on the crit. soly. temp. method in aniline than on the sp. gr. and the  $n$ . Accordingly, the refractometric and the sp. gr. methods can be applied only to fractions b. below 150°. All 4 methods can be used in detg. the aromatic compds. in the fraction b. below 150° and the refractometric and the sp. gr. methods are preferred. For gasolines b. to 200° the aniline and the nitrobenzene methods of detg. the aromatic compds. are best. Volumetric methods are not sufficiently accurate for the detn. of aromatic compds. III. Methods for the determination of the chemical composition of straight-run gasolines and the determination of naphthene and paraffin hydrocarbons. A. N. Sakhanov and M. D. Tilicheev. *Ibid.* 80-104.—It is concluded that chem. methods for the detn. of naphthene and paraffin hydrocarbons are of little use because of the inert chem. nature of these hydrocarbons. A detn. of these hydrocarbons on the basis of their phys. consts. is difficult because of the presence of paraffin and naphthene hydrocarbons of various structures. Therefore, the best method in this case is the aniline method. A phys. sepn. may be effected by (1) distn. under reduced pressure, (2) distn. in the presence of a third ingredient which has a different soly. and (3) freezing out some of the normal paraffins (in some cases also other hydrocarbons). It is thus possible to sepn. narrow cuts of these hydrocarbons (gasoline) into 3 groups; i. e., normal paraffins, branched paraffins and naphthenes. In the exptl. part of this report pure individual paraffin hydrocarbons were obtained by the freezing method. IV. Methods for the determination of the chemical composition of kerosene and lubricating oil fractions. A. N. Sakhanov and R. A. Virabyantz. *Ibid.* 105-35. This investigation was carried out with the principal Russian and some of the American crude oils. Cofls. for the detn. of aromatic compds., naphthenes and paraffins were found in the course of the exptl. procedure which is described. Thus unsatd. compds. were detd. by the I or Br nos. described in XII, while the aromatic compds. were detd. by the  $\text{H}_2\text{SO}_4$  method, 31% vols. (monohydrate) were sufficient for the complete removal of aromatic compds. The amt. of the aromatic hydrocarbons removed may be calcd. by the phys. consts. of the fraction before and after treatment, with the aniline method. The detn. of naphthene and paraffin hydrocarbons left after the removal of aromatic compds. can be effected by detg. their phys. consts. such as their aniline poms. The methane hydrocarbons which are present in the heavier fractions are detd. from the amt. of solid paraffin which is the only satd. hydrocarbon class present in the heavy fractions. V. The chemical composition and classification of crude oils. *Ibid.* 136-74.—On the basis of the methods described in IV the chem. compn. of fractions of 23 crude oils was detd., 50° cuts being investigated. This led to the following classification of crude oils: (1) Paraffinic crude oils (Grozny paraffinic oil, Oklahoma-Davenport, Texas-Mexia, Oklahoma-Tonkawa). The American paraffinic crude oils contain 1.3-2.0% of paraffin, while the Grozny paraffinic crude oils contain 5-9% of wax. Galician, Roumanian and East Indian crude oils are also high in paraffin. The asphaltene content does not exceed 1-1½% and that of resins, 5-6%. (2) Crude oils having an unchanging high proportion of naphthenes are very rare. A typical

crude oil of that kind is the Dossor crude oil which contains 60% and more of naphthenes. (3) Paraffin-naphthene mixed crude oils are also rare. They contain an excess of naphthenes in the lower fractions while the higher fractions have more aromatic compds. These crude oils have 1.5% and more wax, while the content of asphaltene and neutral resins is very small. Surakhanui crude oil is a representative of this class. It contains up to 6% of paraffin. (4) Representatives of the paraffin-naphthene-aromatic class and Grozny mixed-base, light Voznesenskii, light Maikop, Bibi-Eibat and Huntington-Beach (Calif.), crude oils. (5) This class, the naphthene aromatic, is represented by the Grozny mixed base crude oil derived from the upper layers, heavy Maikop, Binagadi, Kirmaki Kaluga and Hull (Texas), crude oil. They contain, as a rule, not more than 0.3% wax but the amt. of neutral resin is high, reaching 15-20%. (6) A purely aromatic crude oil is Perm oil. It is characterized by a high sp. gr. and prevalence of aromatic compds. in all fractions. This type of crude oil is very rare. The analytical procedure of sepg. aromatic compds. from various fractions with the application of liquid  $\text{SO}_2$  and the use of the aniline method is discussed and characteristics of many fractions are tabulated. VI. Content of five- and six-membered naphthenes in straight-run gasolines. A. N. Sakhanov, A. I. Doladugin and I. M. Bogorova. *Ibid.* 175-84. Naphthenes were detd. in gasoline (b. below 150°) fractions by the Zelinskii catalytic dehydrogenation method. The prepn. of the catalysts (Pd and Pt) as well as the analytical procedure is described. The unsatd. compds. obtained simultaneously by dehydrogenation of satd. compds. present in the cuts were detd. by the I method. The aromatic compds. were removed before the detn. of naphthenes. Thus, 60-95°, 95-122° and 122-150° cuts freed from aromatic compds. of the Balakhano-Sabunchi, Surakhanui, Bibi-Eibat, Dossor and Grozny crude oils were analyzed. It was found that Baku crude oils contain up to 50% of six-membered naphthenes, which exceed those of five-membered compds. in the majority of fractions. All the crude oils investigated had a max. of six membered naphthenes in the 95-122° fraction, except Dossor crude oil. VII. The chemical composition of lubricating oils. A. N. Sakhanov and M. A. Butuzhev. *Ibid.* 180-217; cf. C. A. 25, 3816. VIII. Physical properties of lubricating-oil fractions and their relation to the chemical composition. *Ibid.* 218-30. The b. p., mol. wt., viscosity, and flash points of lubricating oils are closely related to their chem. compn. The mol. wts. of lubricating oils having the same viscosity depend upon the chem. nature of the crude oil. It is highest for paraffine crude oil and lowest for asphalt-base (naphthene aromatic) crude oils, the methane-naphthene crude oils occupying an intermediate position. Thus oils of the same tech. application have different mol. wts. Similarly, the b. ps. of the same tech. lubricating oils depend on the nature of the crude oil. They are highest for methane crude oils and lowest for asphalt-base crude oils with methane-naphthene crude oils having an intermediate position. Flash points of lubricating-oil fractions depend on their b. ps. and both depend on the nature of the crude oil. Thus, lubricating oils from methane crude oils are distinguished by a comparatively high b. p. and mol. wt., while those from asphalt-base crude oils have comparatively low b. ps. and mol. wts. IX. Chemical characteristics of paraffins and ceresins. Surakhanui paraffins and ceresins. A. N. Sakhanov and I. G. Zherdeva. *Ibid.* 231-45. Ceresins as well as paraffins form a group of methane hydrocarbons. Ceresins, contrary to the paraffins, produce stable mixts. with oils which cannot be sepd. from the ceresins either by filtration or sweating. Ceresins can be distd. without decompn. if the temp. is kept sufficiently low. At higher temps. they distil under partial decompn. and partial conversion into paraffins. Crude oils contain both ceresins and paraffins. The latter are obtained in the distillates from paraffins already present in the crude oils and only in part from decompd. ceresins. Surakhanui crude oil is high in ceresins which

were sepd. by the authors and investigated. Having the same m. p., the ceresins are distinguished from the paraffins by higher mol. wt., viscosity, b. p. and nitrobenzene ps. The high b. p. of ceresins permits their sepn. from paraffins which distil easily with the distillate while the ceresins are concd. in the residue. Chemically the ceresins are distinguished from the paraffins by the ease with which they are attacked by fuming  $\text{H}_2\text{SO}_4$ . It is possible that ceresins belong to the isoparaffin series; however, this is not yet proved. Paraffins sepd. from Surakhanui distillates are identical with those obtained from Grozny distillates. X. The chemical characteristics of paraffins and ceresins. Grozny paraffins and ceresins. A. N. Sakhanov and N. A. Vasil'ev. *Ibid.* 246-54. The solid hydrocarbons which are sepd. from Grozny paraffinic crude oil belong also to the paraffin and ceresin class, though Grozny crude oil has more paraffins than ceresins. The fractions of Grozny paraffins are similar to the corresponding fractions sepd. from paraffin-contg. tars from brown coal and shale. The paraffins are distinguished by a plate or strip-like structure of their crystals which are closely interwoven. Though an admixt. of oil or tar does not change the structure, an addn. of ceresin acts strongly on the structure of paraffins, changing it into a needle-like, finely cryst. agglomeration. Ceresins from Grozny crude oil are very similar in their phys. properties to those from the Surakhanui crude oil. XI. The chemical composition and structure of asphaltic resinous petroleum substances. A. N. Sakhanov and N. A. Vasil'ev. *Ibid.* 255-85. Asphaltenes in contrast to neutral resins are present in the petroleum in colloidal soln and they can be pptd. quantitatively with an excess of petr. ether for which they are lyophobic. properties. They contain C, H, O and S. Neutral resins form a true soln. in petroleum. On being sepd. by adsorbers in a pure state they are partially transformed into asphaltene, depending on the nature of the adsorber. They consist of C, H, O (and S). The content of asphaltene and neutral resins in different petroleum and their products differs and their presence is indicated by the coloration. The color in the distillates is caused almost exclusively by neutral resins, part of which distils over even with the light gas-oil distillates. The main portion of the resins, however, is left in the distn. residues. The amt. of coke formed in petroleum is in direct relation to the asphalt content, which is the principal coke-forming agent. The coke no. of pure neutral resins is higher, the higher their mol. wt. The coke no. of asphaltene is considerably higher than that of the heaviest resins. An investigation carried out with Grozny asphalt and Balakhano-Sabunchi crude oils and their products shows that the chem. compn. of the resins obtained from the above products is const. Mol. wts. of neutral resins do not exceed 1000 and are of the same magnitude as the mol. wts. of the corresponding distillates. Asphaltene have a considerably higher mol. wt. which is of the magnitude of several thousands. Both asphaltene and neutral resins are highly polycyclic compds. with not more than 1 double bond. The former are formed from neutral resins by condensation which is easily effected by a no. of factors. A further condensation of asphaltene produces the insol. modifications (carbene, carlonds). Neutral resins are formed from the basic petroleum hydrocarbons (and S compds.) by oxidation (and sulfonation). The procedure of sepg. the above substances is described and their compn. and properties are tabulated. XIII. A method for determining the unsaturated compounds in gasolines and heavy petroleum fractions by means of bromine numbers. A. N. Sakhanov, R. A. Virabyantz and A. P. Meshcheryakov. *Ibid.* 322-32. Expts. were carried out with unsatd. compd.-mixts. sepd. from cracked gasoline, with cracked gasoline, gasoline freed from aromatic compds. to which caprylene was added, and with Grozny asphalt-base crude oil. It was found that substitution and addn. products are formed with petroleum when acted upon by halogens. This method cannot, therefore,

be used. In most cases and particularly in fractions b. above 120°, the substitution no. exceeds that of addn. The substitution no. is unreliable because it depends on many factors such as the amt. of reagent used, the degree of exposure to light, and temp. Unsatd. hydrocarbons of high mol. wt. do not react with halogens. XIV. Polarimetric properties of crude oil. A. N. Sakhanov and G. M. Kagan. *Ibid.* 333 42.—The following oils were investigated: Balakhanui, Surakhanui, Binagadui Kirmaki, Bibi-Kibat, Grozny paraffinic, Grozny slightly paraffinic, Grozny, Maikop, Kaluga, Dossor, Makat, Sakhalin, Mexia, Huntington Beach and Hull fuel oils. It was found that the optical activity of methane, methane naphthene and naphthene oils is low, the highest activity being shown by the naphthene-aromatic crude oils. A treatment of the optically active distillates with fuller's earth and H<sub>2</sub>SO<sub>4</sub> does not affect their optical properties. This indicates that aromatic compds. are not the cause of optical activity. Since highly active oils belong to the naphthene-aromatic class, it is concluded that the optical activity is characteristic of highly polycyclic naphthenes.

A. A. Boethling  
The constitution of Ural petroleum (Perm). N. D. Zelinskii and Yu. K. Yur'ev. *Brennstoff-Chem.* 14, 347 9(1933); cf. C. A. 25, 4112 and Sakhanov, et al., part VI of preceding abstr.—Analytical data for 6 fractions between 150° and 240° are tabulated. Aromatic compds. were detd. by both the H<sub>2</sub>SO<sub>4</sub> and the aniline-point methods with different results. Hydroaromatic compds. were detd. as aromatic compds. after catalytic dehydrogenation. Paraffins and naphthene hydrocarbons were detd. by the Carpenter naphthene no. and the aniline point. Aromatic compds. were highest in the 150-70° fraction. Hexahydroaromatic compds. were the same throughout the fractions. Other polymethylene cyclic and paraffin hydrocarbons increased with h. p. Mono-substituted C<sub>10</sub>H<sub>8</sub> derivs. were found only in the 225-240° fraction; all the disubstituted benzenes were o-derivs. Naphthalene hydrocarbons were found neither in the aromatic compds. nor the dehydrogenated hydroaromatic compds. in contrast to the results with Baku oils.

F. W. Jung  
Crude petroleum and petroleum products. G. R. Hopkins. *Bur. Mines, Minerals Yearbook* 1932 33, 459-95(1933). Natural gasoline. G. B. Shua. *Ibid.* 535 44. Asphalt and related bitumens. A. H. Redfield. *Ibid.* 555 64.

Alden H. Emery  
Petroleum-refinery technology. A. J. Kraemer. *Bur. Mines, Minerals Yearbook* 1932 33, 511 15(1933).—The changed status of petroleum refining during recent years is reviewed. All phases of refinery operation have been modernized and cracking capacity has been increased. Developments in purification of gases, methods for processing various fractions, hydrogenations, etc., are described.

Alden H. Emery  
Technical developments in petroleum and natural-gas production. H. C. Fowler. *Bur. Mines, Minerals Yearbook* 1932 33, 497-509(1933); cf. C. A. 27, 4912. The interrelation of oil and gas production and recent developments in engineering research are discussed. A. H. F.

The recovery of hydrogen sulfide from petroleum refinery gases. Ludwig Rosenstein. *Petroleum Z.* 29, No. 24, 4 6(1933).—A practical method for removal of H<sub>2</sub>S is described involving absorption in K<sub>2</sub>PO<sub>4</sub> soln. with the formation of K<sub>2</sub>HPO<sub>4</sub>, KHS and K<sub>2</sub>S, from which mixt. the H<sub>2</sub>S is recovered by heating. The partial pressure of H<sub>2</sub>S at 20° in the vapor above a 2.57 M soln. of K<sub>2</sub>PO<sub>4</sub> contg. 1.53, 1.35, 0.98 and 0.85 mols. of H<sub>2</sub>S per kg. of soln. are, resp., 10, 3.7, 0.9 and 0.4 mm. In practice the rich soln. contg. the H<sub>2</sub>S is pumped on to the top plate of a column and on its journey downward becomes gradually devoid of its H<sub>2</sub>S. The method is superior to absorption in NaHCO<sub>3</sub> soln. or interaction with SO<sub>2</sub>, or polythionates to give free S.

J. M. Levine  
Safety at petroleum-cracking plants. R. L. Marek. *Bur. Mines, Tech. Paper* 551, 92 pp.(1933). The influence of temp. and corrosion on cracking equipment,

selection of proper metals for various equipment, the prevention of corrosion, toxic vapors, inflammable vapors, etc., are discussed.

Alden H. Emery

Conversion of fatty and waxy substances into petroleum hydrocarbons. W. F. Seyer. *Bull. Am. Assoc. Petroleum Geol.* 17, 1251-67; *J. Inst. Petroleum Tech.* 19, 773 83(1933).—The most stable portions of org. tissues are fatty acids. It is assumed that petroleum is formed from a wax-like substance. When a pure hydrocarbon is heated in a bomb a complex liquid and gaseous mixt. is obtained. The reverse does not occur. Hydrocarbons are unstable at high temps.; the rate of decompn. in either the gaseous or liquid phase follows the monomol. law. There is no definite temp. at which reaction begins and the rate of decompn. at any temp. can be calcd. by the Arrhenius equation. When satd. hydrocarbons are heated, unsatd. hydrocarbons are produced and a fraction of them undergoes mol. rearrangement to form satd. cyclic hydrocarbons. Another fraction polymerizes or recombines to form complex hydrocarbons of the branched chain or ring type. The transformation of the waxy substances can be regarded as a sort of low-temp. high-pressure distn. process in which pressure favors the production of cyclic hydrocarbons. Ultimately, only gases, composed of low mol. wt. hydrocarbons and a dense semi-solid or asphaltic material, remain. A. H. L.

Petroleum storage-tank coatings and corrosion in oil-cracking installation. E. Perry. *Paint & Varnish Production Mgr.* 9, No. 11, 10 et seq.(1933).—The corrosion of petroleum-storage tanks by sour crude oils is outlined. The use of noncorrosive alloys is too expensive and therefore paints must be relied upon to prevent the corrosion. The characteristics of various coatings which have been tried are discussed.

G. G. Swaid

Petroleum and synthetic gasoline. Carl Bosch. *Petroleum Z.* 29, No. 27, 1-10(1933).—Destructive hydrogenation of coal is reviewed and its economic importance is discussed.

I. M. Levine

Oil fields of Poland, geological and statistical summary. Charles Bohdanowicz. *Bull. Am. Assoc. Petroleum Geol.* 17, 1084-1097(1933).—B. gives data on the density and quality of crude oil from various Polish oil fields.

Alden H. Emery

Generation of oil in rocks by shearing pressures. IV V. Further studies of effects of heat on oil shales. W. P. Rand. *Bull. Am. Assoc. Petroleum Geol.* 17, 1229 50(1933). Changes produced in the character of fossil org. matter by heating are due to fractional decompn. of its chemically complex structures. The nature of the intermediate products depends in part on the type and state of preservation of the org. material in the shale. Differences in character of sol. products obtained from a given shale under various conditions of heating are not readily apparent; variable results are more easily noted in the amt. of conversion effected and in the vol. of gases produced. Formation of sol. bitumens under thermal conditions in the lab. depends on temp., time and volumetric ratio between the org. matter in the rock and the pore space accessible to gas. Rate of bitumen formation increases with the temp. During the 1st 24 hrs. of heating, approx. 6 times as much bitumen was formed at 300° and 61 times as much at 350° as was formed at 250°. Time is more important at high than at low temps. and during the early part of the conversion process. Vapor pressures sufficient to retard volatilization are necessary to bitumen formation. The org. products formed from oil shale and kindred rocks as a result of heating are derived from their insol. org. constituents by cracking. Some products may be immediately sol. and others immediately volatile. Certain constituents may be broken up repeatedly. The phys. conditions det. the amt. of conversion and the nature of the products formed; in the absence of especially favorable conditions the trend is toward the production of volatile gases and fixed C.

Alden H. Emery

The distillation of Wurtemberg oil shales. Franz Waclaw. *Petroleum Z.* 29, No. 32, 4 7(1933).—By

distn. of 100 tons of shale in a rotary kiln there were obtained 3-6 tons of heavy oil (S 2.4-3.8%), 100 kg. gasoline (S 0.5-3%) and 1800-2200 cu. m. of gas of 7500-9200 B. t. u. The gasoline has a strong odor and does not lend itself to refining because of the large losses entailed and deepening in color. By treatment of the heavy oil with  $H_2SO_4$  an ichthyol-like substance was obtained; ichthyol itself could not be formed since no  $C_4H_8S$  is present. The oils could be used as fuel or Diesel oil. Extn. with  $CS_2$  yielded 1.536% bitumen contg. 3.08% S; with  $K_2CO_3$ ,  $CHCl_3$ ,  $(CHCl_3)_2$ , and  $CCl_4$  the yields were smaller. Conclusion: While the ash from the distn. of the shale can be utilized for hydraulic cement or building material, no good use has been found for the oil. I. M. Levine

**Influence of rotary mud on the production capacity of oil sands.** R. W. Brauchli. *Petroleum Z.* 29, No. 30, 14 (1933).—The influence of the addn. of rotary mud, water, oil (25°Bé. or tank bottoms free from light ends) or aqua gel is discussed. With particular reference to the Oklahoma City field it was found rational to use mud or water while the well was still under high pressure but when the pressure was considerably reduced, production was greatly increased by the addn. of oil or gel. The loss of oil by absorption in the sands is relatively small, viz. 0-13.6%. The subject is reviewed with reference to other fields. I. M. Levine

**Pretreating crude oils with alkali.** A. S. Velikovskii and A. V. Druzhinina. *Neftyanoe Khozyaistvo* 25, 48-55 (1933).—The caustic treatment of Baku crude lubricating oil (a mixt. of light Balakhanui-Sabunchi and light Roumanian crude oils) by using a 4% soln. of NaOH and passing it in countercurrent to the crude at 65-70° lowered the acidity from 2.292 mg. KOH to 0.402 mg., the neutralization being effected up to 96.7%. The caustic sludge had a black color, and its org. part had an acid no. of 124. It contained 36.8% of unsaponifiable substances. The stability and the color of the crude oil were improved and emulsions were not formed, while the distillates had a better color and needed smaller amts. of reagents in the final treatment. Because of the removal of naphthene acids from the crude oil the distn. equipment is not subjected to corrosion. Similar results were obtained with other Baku oils, in some cases the strength of NaOH was changed. All treated oils showed a higher amt. of ash. Heavy crude oils contg. 0.9-1.2% petroleum acids acted less favorably; some of the alkali remained in the oil and quite a high proportion was found in the sludge. Some oils such as the Fimba crude oil formed emulsions which were broken by adding 1% of kerosene naphthene acids. The alkali sludge contained up to 50-60% of oil. The compn. of the org. part sepd. from the sludge from Bibi-Eibat crude oil contained: asphaltogenic acids 0.23, naphthene acids 63.52, asphaltenes 0.96, resins 4.07 and "oil" 31.16%. The oil is composed of the lightest and the heaviest crude-oil fractions. A. A. Bochtlingk

**Isolation of pure benzene from Shukoko crude oil and its identification by comparing its properties with those of pure benzene.** Masakichi Mizuta. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 448-50 (1933).—Pure benzene was sepd. from the crude oil by repeated fractionation and crystn. of the benzene at low temps. Comparison with Merck's c. p. benzene showed that the properties of the 2 were the same. Karl Kummermeyer

**Cracking process.** R. Berl and W. Dienst. *Petroleum Z.* 29, No. 32, 1-4 (1933).—Gas oil was heated for 70, 190 and 310 min. at 400° and 425° under pressures of 18 and 24 atms. under conditions wherein the gasoline and gas were continuously removed as formed. The gasoline yields at 425° were 4 times the yields at 400°. I. M. L.

**Cracking with liquid metal as heat-transfer medium.** Alfred Oberle. *Petroleum Z.* 29, No. 25, 1-2 (1933)

I. M. Levine  
**Determination of unsaturated and aromatic compounds in cracked gasoline.** S. S. Nametkin and E. A. Robinson. *Neftyanoe Khozyaistvo* 24, 184-6, 230-3 (1933).—The authors carried out expts. on synthetic mixts. of 60-95% cuts of dearomatized gasoline with various proportions

of cyclohexene, benzene and amylene. It was found that the completeness of removal of aromatic and unsatd. compds. with  $H_2SO_4$  depends upon the structure of the unsatd. compds. present as well as on the ratio of the above hydrocarbons in the mixt., and on the concn. and the amt. of  $H_2SO_4$  used. Thus, mixts. contg. about 20% of cyclohexene and 15%  $C_6H_6$  are freed from these hydrocarbons after treatment by the Kattwinkel method, by use of 3 parts of the mixt. and 1 part of the reagent and shaking for 100 min. However, a mixt. contg. 20% amylene and 10%  $C_6H_6$  still contains 8-10% of unsatd. compds. Mixts. contg. relatively less unsatd. compds. (50% of the aromatic compds.) contain 23% of polymerization and condensation products which are not removed by the above reagent.  $H_2SO_4$  treatment with acid of gradually increasing strength effects a removal of some of the aromatic and unsatd. compds. while the Kattwinkel reagent leaves 10%. When the Kattwinkel soln. is used first, followed by treatment with  $H_2SO_4$  contg. 1% of  $SO_3$  at -5°, 15% remains; repeated treatment with oleum removes another 2 1/2% which indicates an attack of satd. hydrocarbons. Narrow cuts of cracked gasoline were treated with 80, 90, 94 and 98%  $H_2SO_4$  with 1 vol. of gasoline and 2-3 vols. of acid with shaking for 20 min. In another series the Kattwinkel soln. was used. The latter soln. was more effective than the  $H_2SO_4$ , although identical results were obtained with a preliminary treatment with  $H_2SO_4$  of lower strength followed by the Kattwinkel treatment. The deviation of results obtained by the  $H_2SO_4$  method from that of the Kattwinkel method may amount to 30%. In the detn. of unsatd. compds. in the presence of aromatic compds. the  $H_2SO_4$  cannot be applied because of the attack of the  $H_2SO_4$  on both aromatic and unsatd. hydrocarbons. The benzoyl peroxide method was found to be very dependable with synthetic mixts. such as menthene-gasoline, menthene-benzene, limonene-menthane. The detn. of unsatd. compds. by the above method in narrow cuts of cracked gasoline showed deviations not exceeding 1 1/2%, provided that 30-50% of unsatd. compds. were present. A. A. B.

**The mechanism of detonation, or knocking, in internal-combustion motors.** Charles Dufraisse and René Chauv. *Compt. rend.* 197, 672-4 (1933).—The peroxide theory of detonation was not originated by Dumanois (*C. A.* 22, 1406; 27, 5955). Gerald M. Petty

**New catalytic processes for the production of motor fuels having high octane number.** Anon. *Oil Gas J.* 32, No. 22, 12, 31 (1933).—The Houdry process is described which cracks the oil in the presence of steam over molar solid catalyst. The untreated gasoline is low in gum and S and has excellent  $O_2$ -bomb stability. J. R. S.

**Commercial application of the "Chlorex" process in the manufacture of high-grade motor oils.** W. H. Bahlke, A. B. Brown and F. F. Diwocky. *Oil Gas J.* 32, No. 23, 60, 62, 72 (1933).—A review of the com. application of "Chlorex" ( $\beta, \beta'$ -dichloroethyl ether). Diagrams, tables and charts are given. J. R. Stroug

**Use of furfural as the extraction solvent to make motor oils having low viscosity index.** R. E. Manley, B. V. McCarty and H. H. Gross. *Oil Gas J.* 32, No. 23, 78, 79, 81, 82 (1933).—Furfural manufd. from agricultural wastes is cheap and has a high degree of selective solvent action on a wide variety of lubricating stocks. It is stable in a closed system, and has the advantage of high application temp. (300° F.). It is non-poisonous. A flow chart of the plant is given as well as data secured in testing various stocks. J. R. Strong

**Pyrolysis of the Surakhanui paraffinic fuel oil.** N. A. Butkov, E. I. Rabinovich and T. P. Kolpenskaya. *Neftyanoe Khozyaistvo* 25, 29-35 (1933).—In the vapor-phase cracking of Surakhanui paraffinic fuel oil an app. consisting of an iron retort 1 m. long and 5 m. in diam. was used. It was heated electrically and the temp. was kept const. within 5°. The pressure in the retort was maintained at about 5 mm. Hg, and the cracking stock was charged at the rate of about 2.5 cc. per min.  $C_2H_4$  (detd. by the Allosway method) amounted to 0.08% (by vol.) when cracking at 700°, 0.09% at 750° and 0.12%

at 650°. The Surakhanui mazout used had a sp. gr. of 0.894, initial b. p. 205°, below 300° 10%,  $E_{50}$  viscosity 3.54, ash 0.12%, paraffin (Hofde) 4.21%, pour point (Hofde) +20° and Brenken flash 126°. The yield of light fractions amounted to 18% and was almost const. regardless of the cracking temp., while their sp. gravities changed with temp., amounting to 0.850 at a cracking temp. of 700°. The "naphthalene" yield increased with increase in cracking temp., reaching 2.7% at 800°. The yield of pitch decreased from 20 to 13% with increase in temp. from 650° to 700° and remained const. on a further temp. increase. The vol. of gas increased with cracking temp. but the yield by wt. decreased. An increase in cracking temp. caused a decrease of the sp. gr., the calorific value and the content of higher olefins while the amt. of  $H_2$  increased. The influence of the cracking temp. on various aromatic compds. was as follows: Increase in temp. raised the yield of  $C_{11}H_8$ , while that of  $C_{10}H_8$  had a max. of 3.6%, decreasing on a further increase in cracking temp.  $C_{11}H_8$  contained a max. of 16% of unsatd. compds. while  $C_{10}H_8$  had a max. of 10.5%. The yield of coke was detd. separately in a porcelain tube, the tar being removed with  $CaH_2$ . The yield of coke varied between 4.15 and 7.37% while that of lamp black was 2.51-6.35%, yields about 5 times higher than those found on cracking kerosene distillate. The yield of pitch reached 4% calcd. on the cracking stock. The gases from cracking Surakhanui paraffinic fuel oil contained amylene and  $C_{11}H_8$  1.7%, diolefins (butadiene) 1.0-2.2, isobutylene 2.3, butylene and propylene 11.0, ethylene 19.18,  $H_2$  12,  $CO$  and  $O_2$  3.0, methane 38 and ethane 12%.

A. A. B.

**Substitute Diesel fuels.** Donald A. Howes. *Mining J.* 182, 583-4, Adv. sect. viii (1933).—There are few, if any, supplies of alternative Diesel fuels. Coal-tar oils of aromatic nature are unsuitable because of their high ignition temp. and long delays between injection and ignition. Even after hydrogenation and conversion into a mixt. of naphthalenes, the product probably would not be satisfactory, because naphthenic oils of petroleum origin are inferior to paraffin and mixed-base oils, and costs are high. Polymerization of olefins under pressure will give satisfactory oils, but costs are prohibitive. Shale oils often are satisfactory Diesel fuels, but a better return can be obtained by cracking to form gasoline. Cracked vegetable oils give a low power output. The most promising field is the development of antiknock agents for coal-tar oils.

Alden H. Emery

**Chemical nature of gum-forming constituents in gasoline.** D. T. Flood, J. W. Hladky and G. Edgar. *Ind. Eng. Chem.* 25, 1231-40 (1933).—Individual hydrocarbons of the type likely to be formed by cracking were added in varying amts. to straight-run paraffinic gasoline and the mixts. subjected to the usual gum-stability and storage tests. The largest amts. of gum were developed in the mixts. contg. aliphatic or cyclic diolefins or mono-olefins attached to a benzene ring. In certain cases large concns. of aliphatic mono-olefins also formed appreciable quantities of gum. Gum formation was found to be almost invariably assocd. with oxidation. It was found that the action of inhibitors consists in prolonging the induction period without apparently affecting the rate of  $O_2$  absorption once the induction period is finished. No simple relation was found between the time of stability in storage and the length of the induction period detd. by the  $O_2$  bomb. It is suggested, however, that a study of the complete  $O_2$  bomb pressure curve may give valuable indications of the behavior of the mixt. in storage.

D. F. Brown

**Recent developments in the gum problem.** W. H. Fulweiler. *Gas Age-Record* 72, 411-3 (1933); cf. 1 27, 318. —A discussion of the relation of NO concn. to gumming troubles. Late studies have shown that the danger limit must be moved from 6 g. of NO per million to 2 or less.

H. L. Ohm

**Solubility of hydrogen and natural gas in oils at high operating temperature and pressure.** V. V. Ipat'ev, Jr., V. P. Teodorovich and I. M. Levine. *Oil Gas J.* 32, No. 20, 14-30 (1933).—The solv. of  $H_2$  in benzene, toluene,

1 xylene, as well as in gasoline, kerosene, cylinder oil and mazout, increased in proportion to the pressure up to 500 atm. The solv. of  $H_2$  in hydrocarbons decreased with the complexity of the mol.  $CH_4$ , unlike  $H_2$ , decreased in solv. with increased temp.

J. R. Strong

**Colloid graphitic oils and pastes.** E. Helani. *Petroleum Z.* 29, No. 31, *Motorbetrieb und Maschinen-Schmierung* 6, No. 8, 5-8 (1933).—The subject is reviewed in particular connection with roller and ball bearings. A suitable product is one in which the colloid is stable and homogeneous; the particle size of at least 70% of the graphite is 0.1-0.3  $\mu$ , and no gummy substances are formed. It is suggested that pumps be used for lubrication with this type of prepn. The graphitic film on the bearing wall is discussed.

I. M. Levine

**Smoke point of kerosene.** Anon. *J. Inst. Petroleum Tech.* 19, 812-11 (1933). App. and procedure are described for detg. the max. height of flame with which a kerosene will burn without smoking.

E. E. C.

**Vapor-gathering systems with steel balloons reduce evaporation and corrosion losses.** T. E. G. Bignell. *Oil Gas J.* 32, No. 21, 8, 54 (1933).—The use of steel balloons in the petroleum field is described.

J. R. S.

**Some of the theoretical and practical aspects of the acid treatment of limestone wells.** M. E. Chapman. *Oil Gas J.* 32, No. 21, 10, 53, 54 (1933).—The com. use of inhibitors for the protection of metals in acid solns. has resulted in the development of inhibitors which have largely eliminated the damage by acid corrosion to well casing or other equipment.

J. R. Strong

**Catalytic influences in autoignition processes.** Carl Zerbe, Franz Beckert and Hermann Jentzsch. *Angew. Chem.* 46, 650-62 (1933).—The catalytic influence of 22 metals and metal compds. upon autoignition in pentane- $O_2$  and benzene  $O_2$  mixts. was investigated and the results are presented in graphical form. The min.  $O_2$  requirements and the accelerating or retarding actions of the catalysts were detd. The contact mechanism was discussed. In the presence of catalysts it was found that the autoignition is still mainly dependent upon temp.,  $O_2$  concn., and the chem. constitution of the inflammable material.

Karl Kaunmeyer

**The analysis of lubricating oils.** Tepugov. *Compt. rend. cong. Graissage* 1931, 63-73, *Chem. Zentr.* 1932, 11, 2575-6. —Tables show anomalies in detns. of the solidifying points of various oil mixts. These points may be either higher or lower than the values calcd. from the solidifying points of the constituents and their relative proportions. Shortly after heating, the solidifying point is higher but it sinks again in a few days. In detns. of the acid no. it was found that the method of Mahler gave values as accurate as the standard method of Hofde and effected a saving of time. Ten g. of the oil is boiled with 25 cc. neutral abs. alc. in a 250-cc. Erlenmeyer flask for 1 hr. and then titrated with NaOH. A blank must be run. In the usual viscosity measurements based upon the principle of Poiseuille the temp. of the oil is noted before passage through the capillary, the vol. being measured in the vessel receiving the oil. In the Engler, Redwood and Saybolt viscometers no provision is made to prevent cooling of the oil after flow. Comparative expts. showed that the error in vol. due to contraction upon cooling (initial temp. 100°) can be neglected for technical work. *Methods of obtaining oils of high viscosity without heating* are reported. A cylinder oil of viscosity 5.5 at 100° was shaken with 2 vols. ether and 1 vol. 96% alc. in a separatory funnel. After distg. off the solvents and drying at 100°, the upper layer yielded an oil (75% wt. of the original) of viscosity 6.8. The lower layer after the same treatment yielded an oil of viscosity 4.6.

W. A. Moore

**The slope of the viscosity-temperature function as an important characteristic of lubricating oils.** H. Umstätter. *Petroleum Z.* 29, No. 31, 1-3 (1933).—The slope  $B = (\log \log \eta' - \log \log \eta) / (\log T - \log T')$  is given for several com. lubricating oils. An oil is more serviceable the lower the slope, for it is shown that the

coeff. of friction varies directly with the slope. *B* cannot be made to coincide with viscosity index. I. M. L.

The evaluation of automobile lubricating oils from the point of view of formation of carbon deposits. N. I. Chernozhukov. *Nefyanoe Khozyaistvo* 24, 234-40 (1933).—Fresh lubricating oils were tested for sp. gr., flash,  $E_{100}$  and  $E_{100}$  viscosities, acidity, sulfonates, Conradson C, ash, NPA color, Sly, and Grozny and Butkov oxidizability, including the acid and residue detn. as a result of oxidation, and distn. test (at 2 mm. Hg) in a stream of  $CO_2$ . The spent oil was tested in the above manner except for its oxidizability. The engine tests were run on a 6-cylinder AMO-2 (Hercules type) motor of 60 h. p. and a single-cylinder motor 1-3 of 3 h. p., which were run for 60 hrs. It was found that acidity causes an increased amt. of Fe in the C deposit. An increased content of a fraction b. below  $225^\circ$  (2 mm.) causes an increase in the C deposit; this behavior depends also on the type of refining. An increase of the acidity after oxidation (by 1 of the 3 methods specified) shows an increased acidity in the spent oil in the crank case. The amt. of burned oil does not depend on the b. p. of the oil but evidently on the vaporization of fractions. The Conradson C test is not a criterion on the behavior of the oil in the engine. Residual oils form a hard C deposit. The oils must be properly acid treated and washed with alkali. The stability of oil may be tested by the Sly method. An oil should not give more than 0.3% residue and its acidity should not exceed 0.8 mg. KOH. The expl. procedure is described and the results of tests are tabulated and plotted. A. A. B.

Lubricating properties of greases from petroleum oils. F. H. Rhodes and H. D. Allen. *Ind. Eng. Chem.* 25, 1275-80 (1933). Tests of greases in an app. developed by A. W. Lewis and modeled after the Wilson-Barnard app. indicate that the soap in soda-base greases is an important factor in the formation of the lubricating film. The glycerol present helps to stabilize the structure of the grease, reduces the change in consistency on heating or working, increases the lubricating power, eliminates the increase in the coeff. of static friction on heating, and reduces the susceptibility to moisture. The best lubricating greases are those containing 2-3 times the quantity of glycerol equiv. to the soap present. The lubricating value of the grease decreases with either increase or decrease of this amt. of glycerol. D. F. Brown.

Use of two immiscible solvents for the manufacture of lubricating oils by the extraction process. Max. H. Miller. *Oil Gas J.* 32, No. 21, 11, 62; *Natl. Petroleum News* 25, No. 41, 26-8 (1933).—The 2 immiscible solvents pass countercurrently while the oil is fed in the center of the system. As it is sepd. into the paraffine and naphthene fractions the 2 phases flow countercurrently with their resp. solvents, stripping each other of the final traces of the undesired fraction. J. R. Strong.

Application of the solvent extraction method for improvement of lubricating-oil quality. John W. Poole and J. M. Wadsworth. *Oil Gas J.* 32, No. 23, 49, 50, 52 (1933).

J. R. Strong.  
Trolley-wire lubrication improved. J. V. Lamson. *Ele. Eng.* 52, 771-6 (1933).—"Lab. tests indicate that solid graphitic material for trolley-wire lubrication is vastly superior to the graphite-grease now commonly used." The general problem of trolley-wire lubrication is discussed briefly and the results of tests on both types of lubricants are indicated. W. H. Boynton.

Rationalization of the charcoal industry. I. Dorofeev-Silant'ev. *Lesokhm. Prom.* 1, No. 3-4, 14-19 (1932).—It is proposed to discontinue firing of wood-carbonizing kilns as soon as a temp. of  $280^\circ$  is reached. The exothermal reaction which sets in at this point is assumed to be sufficient to carbonize the wood. An addnl. firing is recommended after the completion of the exothermal reaction. Various changes in the construction details of the Schwartz kiln are recommended and its advantages are analyzed. Reply. A. A. Nimvitzki. *Ibid.* 19-21.—N. contradicts the assumption that the exothermal reaction takes place very gradually; i. e., that while the upper layers of wood are being carbonized under the

influence of the exothermal reaction, the lower layer is still wet and water is accumulating in that region. Therefore, the heat produced by the exothermal reaction is entirely inadequate for continuing the process without the introduction of external heat. A. A. B.

Creosote from tar obtained as residue in the rectification of "black" acetic acid in the Vilesov experimental extraction plant. A. L. Piryatinskii and L. F. Saenkov. *Lesokhm. Prom.* 1, No. 3-4, 21-3 (1932).—A dil. AcOH soln. (cf. Nasakin, *C. A.* 23, 3077) was steam distd. and the distillate contg. AcOH as well as resins and higher boiling fractions was investigated. The fractions b.  $110-260^\circ$  obtained from the residue by distn. (54% of the residue) had a sp. gr. of 1.07 and acidity of 14.76% (calcd. as AcOH). They were used in the sepn. of creosote. This distillate was redistd. into 2 fractions, the first fraction having an acidity of 17.81%, and a b. p. of  $98-180^\circ$  while the second fraction had a b. p. of  $180-240^\circ$ . The latter was treated with a 10% soln. of calcined soda for the removal of free acids and the oil obtained was treated with a 8-10% soln. of caustic soda (an excess is used). The phenolates sepd. from a small layer of oil were heated with open steam for the removal of substances which did not combine with the alkali. The cooled soln. of phenolates was acidified with a 30%  $H_2SO_4$  to a clear acid reaction and the floating oil (phenols) was sepd. from the  $H_2O$  layer contg. water-sol. phenols (which were sepd. by salting out and were added to the basic portion). The phenols were neutralized with a 5% calcined soda soln. and washed with water. The pure phenols were distd. into 2 fractions and a residue boiling above  $240^\circ$ . The yield of the fraction b.  $180-240^\circ$  amounted to 9.56% of the resins and produced a clear soln. when 1 cc. was mixed with 2.5 cc. of a 15% NaOH soln. which could be diluted to 50 cc. before the appearance of turbidity. The heavy fraction b.  $200-220^\circ$ , conforming with the requirements of the U. S. S. R. Pharm. and obtained in the distn. of the purified phenols, was treated with a 10% soln. of NaOH (with slight excess) and blown with steam till transparent and treated in the same manner as the low-boiling fraction. The liquid was then distd. into 4 fractions and the combined first 3 fractions b.  $98-220^\circ$  were treated with chromic acid mixt., left stand overnight and redistd. The second fraction b.  $200-220^\circ$ , which amounted to 3.86% of the resin, was an only substance with a high  $n$ , a slightly yellow color and a sp. gr. of 1.090, yielding 96.5% with a b. p. of  $200-200^\circ$  on redistn. by Engler-Ubbelohde. It passed all tests prescribed by the U. S. S. R. Pharm. except that for the presence of coal-tar phenols. A. A. B.

Crude turpentine obtained from stumps. A. L. Piryatinskii and L. A. Segeidin. *Lesokhm. Prom.* 2, No. 2, 47-9 (1933).—The crude turpentine is characterized by the presence of heavy ends (pine oil), composed mainly of terpene aces., which are used as flotation agents, solvents and disinfectants. It has the following characteristics: sp. gr. 0.8732, Br no 172,  $n_D^{20}$  1.4726, b. p.  $153-180^\circ$  (residue b.  $180^\circ$ , 19%), aces 9.61% (calcd. as  $C_{10}H_{18}O$ ), esters 0.44% (calcd. as  $C_{10}H_{17}OCOCH_3$ ). In a steam distn. in the lab., 16 fractions were sepd. The distillates can be classified into 2 groups. The first group is characterized by its lower sp. gr. (0.8617-0.8622), low aces. content and high content of terpene hydrocarbons. The 2nd group is a straw-yellow liquid of a higher sp. gr. (0.8932-0.9367) and has a high content of aces. (up to 40%) and a considerably higher  $n$ . The first 6 fractions constitute a high-grade turpentine with a high content of pinene fraction. The 7-11 fractions can be classified as a 2nd-grade turpentine which can be used as a solvent in the varnish industry. The intermediate (12th) fraction can be recycled together with a new charge, while the higher fractions (about 13.5%) can be used as the stock in the prepn. of high-grade pine oils. The residue (about 4.5%) is a viscous, heavy substance that may find application in the rubber industry. A. A. B.

Siberian larch, a new raw material for the chemical industry. L. V. Gordon. *Lesokhm. Prom.* 1, No. 3-4, 24-7 (1932).—The Siberian larch contains an av. of

3.4% fiber impregnated with gum and the fiber contains about 14% of gum by wt. The extn of gum is carried out with water in the usual manner resulting in a yellowish oil contg about 3% of gum. The unrefined gum is bleached and is suitable for the manuf of silk goods, matches and as a substitute for gum arabic, although it is not quite as sticky. The bark of the young larch contains 10-12% and more of tannins and larches of 150-250 years containing only 7-8% tannins, which, however, are of a much higher grade contg 70-80% of the dry substance in the ext. This makes it possible to use smaller quantities of tanning substance than when oak bark is used. About 40-42% of cellulose is produced from the dry substance with the sulfate method. Larch chips are used in this process and they are treated with a 25-30% alkali. The chips are treated with the smallest possible amt of alkali to obtain fiber, followed by the removal of the major part of the accompanying lignin, etc., by treatment with  $\text{Cl}_2$  or  $\text{Cl}$  water and the final bleaching is carried out with  $\text{Ca}(\text{OCl})_2$ . A. A. B.

Place of oil in the world of fuel (Cadmin) 21.  $\text{H}_2\text{SO}_4$  from heavy refinery sludge (Spangler) 18. Olive oils as lubricant (Lichim) 21. Testing lubricant (Brit pat 395,976) 19. Purifying gasoline vapors with  $\text{Cu}$  oxide (U. S. pat 1,920,659) 1. *peri* Monooxynaphthene (Brit pat 394,511) 10. Seal for floating deck of tanks for storage of petroleum oils (U. S. pat 1,930,953) 1. Aqueous dispersions such as those of oils, fats and fatty acids (U. S. pat 1,930,945) 13. Trepan barbourite for oil treatment (U. S. pat 1,930,572) 4.

**Treating petroleum with sulfuric anhydride** Wright W. Gary (one half to Charles O. Middleton) U. S. 1,929,480, Oct. 10. In order to remove S compounds, etc. a petroleum oil is contacted with  $\text{SO}_2$  maintained in a dry and viscous state the reaction product is separated and the remaining petroleum material is contacted with an agent such as  $\text{H}_2\text{SO}_4$  adapted to coagulate the remaining unreacted reaction product. (Cl. C. 1, 27, 299)

**Breaking petroleum emulsions** Abraham M. Holzman (to Industrial Patent, Ltd.) U. S. 1,931,112, Oct. 17. An emulsion such as a natural petroleum and water emulsion treated with chloroform (suitably in very small proportion) and the emulsion is then allowed to remain at rest to permit stratification of oil and water. App is described. "Chloroform" or the like also may be used.

**Purifying petroleum sulfonic acids** Kolchali S. Ramayya (to I. Somachorn, Son, Inc.) U. S. 1,930,488, Oct. 17. Impure alkali metal and  $\text{NH}_4$  salts of the monohydric sulfonic acids derived from the treatment of a petroleum oil with  $\text{H}_2\text{SO}_4$  are dissolved in a solvent containing water 75-75% together with  $\text{MeOH}$ ,  $\text{EtOH}$  or  $\text{PrOH}$ , and the resultant mixture is agitated with a petroleum hydrocarbon material such as gasoline boiling mainly below 300. The agitated materials are permitted to stratify producing a solvent layer and a hydrocarbon layer, the solvent layer is separately collected and the purified salts of the monohydric acids are recovered from the solvent layer.

**Distilling petroleum residues** George B. Conbrough (to The Tinnus Co.) Brit. 34,856, July 11. See 17,745,375 (Cl. 1, 27, 434C).

**Disposing of wastes from petroleum refineries, etc.** Marvin L. Chappell and Richard P. L. U. S. 1,929,675, Oct. 10. In disposing of waste product containing S compounds by combustion in a heated zone with air, the heated zone is maintained at temps above the decomp. temp. of  $\text{SO}_2$ , and the heated products of combustion are quickly cooled below a  $\text{SO}_2$  forming temp by introduction of water into the combustion products as they pass from the heated zone into a condit. App is described.

**Arrangement of apparatus for refining petroleum oils, etc., by use of solid reagents such as fuller's earth** Rudolph C. Osterstrom and Robert L. Tucker (to Pure Oil Co.) U. S. 1,930,597, Oct. 17.

**Treating cracked petroleum distillates for removing gum-forming and color-producing substances** Joseph B. Weaver U. S. 1,929,861, Oct. 10. A mixt. of the distillate with added finely divided acid-treated clay is passed in a generally upward direction through a vertical treating zone while agitated and heated sufficiently to vaporize the low boiling constituents present. The evolved vapors are fractionated and separately condensed and collected. The remainder of the mixt. is removed from adjacent the upper end of the treating tower and is subjected to redistill under temps higher than those prevailing in the treating zone to sep desired low-boiling products from the residual mixt. and material of higher bp. App and various details of operation are described.

**Oxidation of hydrocarbons** Grigory S. Petroff, Alexander J. Danilowitch and Abram U. Robinowitch (U. S. 554,110, Sept. 20, 1933. Higher naphtha hydrocarbons are oxidized to acids by treatment with an (preferably dried) at 95-125° in the presence of a catalyst comprising an oil sol. mixt. of free naphthenic acids with naphthenates of  $\text{Ca}$ ,  $\text{Ba}$  or  $\text{Mg}$ .

**Hydrocarbon oils** Wm. I. R. Bindley Brit. 394,506, June 20, 1933. Divided on 396,982 (C. A. 27, 4655). Hydrocarbon oils are produced by passing mixts. of  $\text{CO}$  and  $\text{H}_2$  at atm pressure and at 205-230° over catalyst consisting of oxides of  $\text{Co}$  and  $\text{Mn}$  with which may be mixed  $\text{Ca}$  is metal or oxide and  $\text{Ca}$  oxide. The powder granular catalysts are attached to supports by spraying or otherwise coating the support with a binder and sprinkling the catalyst onto it while it is still tacky.

**Cracking and coking oils** Universal Oil Products Co. Brit. 333,847, July 6, 1933. The residues from the reaction drum of a tube and reaction drum-cracking plant are immediately discharged through a line into a coil where they are heated rapidly to prevent deposition of coke and then introduced into coking chambers, preferably used alternately and maintained at reduced pressure relative to that maintained in the drum. Liquid residues or mixed vapors and liquids may be fed through the line. App is described.

**Oil cracking to produce gasoline** Arthur D. Smith and Norman H. Rinstead (to Jenkins Petroleum Process Co.) U. S. 1,929,955, Oct. 10. An oil such as crude petroleum is heated to distil off light constituents including gasoline present in the oil. Heavier ingredients are fractionally condensed and sep'd from the resulting gasoline vapors. The oil is then subjected to pressure cracking in liquid phase to produce additional gasoline and other oil vapors and the heavier portions of vapors thus produced are condensed in 2 stages and the condensate from the first stage is returned to the liquid phase cracking reaction while returning sep the condensate from the second stage. Residual oils are withdrawn from the cracking reaction and pressure on them is reduced while they are still heated to flash a portion into hot vapor. A portion of these hot vapors is passed in heat interchange with the hydrocarbon oils before they are subjected to the cracking reaction to heat the hydrocarbon oils and distil off light constituents. A portion of the unvaporized residual oils is passed in heat interchange with the heavier ingredients and condensate from the second stage to effect a substantial reevaporation and the resulting vapors are subjected to vapor phase cracking to produce gasoline vapors and heavier liquid condensates. App is described.

**Distilling and cracking oils** Standard Oil Co. Brit. 331,745, July 6, 1933. In distilling or cracking oils, e. g., in a tubular furnace from which the heated oils pass to 1 or other of a battery of reaction drums, the oil is fed to the drum through a continuous loop way in which a free passage of the oil is maintained throughout the whole loop and the oil flows in opposite directions to the selected drum. App is described.

**Cracking hydrocarbon oils** Jean D. Seguy (to Universal Oil Products Co.) U. S. 1,927,187, Sept. 19. The oil is passed in a restricted stream through a heating zone in which it is heated to a cracking temp under pressure and then is passed to a reaction chamber

maintained under cracking pressure and temp. conditions and in which the velocity of the oil is materially reduced; unvaporized oil is continuously removed from the reaction zone and is flash-distd. in a flashing zone by pressure reduction; resultant flashed vapors are removed from the flashing zone, and a portion of such vapors, prior to condensation, is passed to a vapor-phase-cracking zone maintained at cracking temp. and from such zone into the unvaporized oil undergoing distn. in the flashing zone to augment vaporization in such zone. The remaining portion of the flashed vapors from the flashing zone is condensed. App. is described. Cf. C. A. 27, 5180.

**Cracking hydrocarbon oils.** Jean Delattre-Seguy (to Universal Oil Products Co.). U. S. 1,929,795, Oct. 10. Oil is heated to a cracking temp. in a heating zone such as a pipe coil in a furnace and is then delivered to an enlarged reaction zone in which conversion takes place. A body of reflux condensate is maintained in a second enlarged zone and vapors from the first enlarged zone are passed in direct contact with material in the second enlarged zone and vapors and reflux condensate in the latter are heated to a higher temp. than that used in the first heating zone. Vapors from the second zone are subjected to reflux condensation and the reflux condensate sepd. from the vapors is passed to the second enlarged zone to supply the body of reflux condensate maintained in that zone. A suitable superatm. pressure is maintained on the oil in the heating zone and first enlarged zone while maintaining a higher superatm. pressure on the body of reflux condensate and vapors in the second enlarged zone. App. is described.

**Cracking hydrocarbon oils.** Joseph G. Alther (to Universal Oil Products Co.). U. S. 1,930,221, Oct. 10. Oil is heated under superatm. pressure to a cracking temp. in a heating zone such as a pipe coil and the heated oil is passed to a conversion zone. Vaporous products are sepd. from the heated oil and unvaporized oil is continuously withdrawn from the conversion zone at such a rate as to prevent substantial accumulation. The pressure on the withdrawn oil is reduced while it is in heated condition to release lighter fractions in the form of vapors which are sepd. and removed while the withdrawn oil is maintained in a substantial body. Solid and semi-solid materials are settled and supernatant liquid oil freed from these materials is sepd. and returned for retreatment to the oil undergoing cracking. An arrangement of app. is described. Cf. C. A. 27, 2797.

**Cracking hydrocarbon oil.** Gustav Egloff (to Universal Oil Products Co.). U. S. 1,930,231, Oct. 10. A body of oil is maintained under cracking conditions of temp. and pressure in an enlarged zone, vapors from which are passed to a dephlegmator in which insufficiently cracked fractions are condensed. Reflux condensate, free from addnl. oil, is passed through a heating zone where it is heated to a cracking temp. and is then delivered into the body of oil in the enlarged zone to which also charge oil is continuously admitted (a portion of the charging oil being discharged into the vapor space above the oil body and another portion being discharged into the liquid oil body below its surface). The process is carried out under superatm. pressure. App. is described. Cf. C. A. 27, 5900.

**Cracking hydrocarbon oils.** Wm. M. Stratford (to Texas Co.). U. S. 1,930,730, Oct. 17. Oil such as gas oil is subjected to cracking and vaporization in a cracking zone comprising a still under superatm. pressure forming evolved vapors of low-boiling and higher-boiling constituents. Products undergoing cracking and contg. constituents of the low-boiling character are withdrawn from the cracking still and passed to a stripping still, and without reducing the pressure in the stripping still there is introduced into it a fluid such as steam adapted to lower the partial pressure therein so that vapors are evolved comprising the low-boiling constituents mentioned. Evolved vapors from both the cracking and stripping stills are passed to a common fractionating zone and there fractionated under superatm. pressure.

1 Residue is withdrawn from the stripping still substantially free from low-boiling constituents and is passed to a second stripping still maintained under a substantially reduced pressure to vaporize constituents of higher b. p. adapted and used for recycling to the cracking zone for further cracking. An arrangement of app. is described.

**Combined cracking and destructive hydrogenation of hydrocarbon oils.** Frederick W. Sullivan, Jr. (to Standard Oil Co. of Ind.). U. S. 1,927,074, Sept. 19. Material such as gas oil or "reduced crude" oil is heated to about 425° in a closed conduit. A light hydrocarbon gas such as refinery gas is heated in an elec. arc by which it is decompd., activated and raised to a high temp., and the hot reaction products from the elec. arc are combined with the heated hydrocarbon material in the conduit so the temp. of such material is raised to about 500° and the reaction products of the arc treatment combine with the heated hydrocarbon material in the conduit. App. is described.

**Apparatus for cracking hydrocarbon oils.** Sigbert Seelig. Ger. 579,684, June 29, 1933. Addn. to 535,277 (C. A. 26, 1111).

**Cracking and preheating stills for hydrocarbon oils.** Willis F. Sims and Venus U. Cloer (to Panhandle Refining Co.). U. S. 1,930,372, Oct. 10. Various structural and operative details are described, of stills and furnace setting.

**Conversion of hydrocarbon oils.** Audley E. Harnsberger and Clyde L. Smith (to Gyro Process Co.). U. S. 1,927,829, Sept. 26. A hydrocarbon oil such as topped crude or gas oil is heated to a vaporizing temp. without substantial pyrolytic conversion (suitably in a pipe system) and the heated oil is then vaporized in a sepg. zone and vapors are withdrawn from the latter and are heated in an elongated confined stream to temps. not substantially in excess of active vapor-phase cracking temps. to vaporize liquid oil entrained in the vapors; the velocity of the dried vapors is increased and they are then heated to temps. above 540° to effect pyrolytic conversion and the temp. of the conversion products is then sharply reduced by admixt. with cool hydrocarbon oil. Various details of app. and operation are described.

**Conversion of hydrocarbon oil.** Claude W. Watson (to Texas Co.). U. S. 1,929,520, Oct. 10. Oil such as topped crude oil or the like is heated to a cracking temp. under superatm. pressure. Lighter products in vapor form are sepd. from unvaporized residue and the residue is expanded by reducing the pressure on it, to form addnl. vapors. The pressure on the vapors of the lighter products is further reduced (but to a pressure still in excess of that on the expanded residue) and the kinetic energy of the expanding vapors of the lighter products is utilized to entrain the addnl. vapors mentioned and to increase the pressure on them. The resulting mixed vapors are fractionated to obtain a product of the character desired. App. is described.

**Conversion of hydrocarbon oils.** Douglas P. Bailey (to The Texaco Development Corp.). Can. 335,818, Sept. 19, 1933. Higher-boiling hydrocarbon oils are converted into lower-boiling oils by heating a condensate oil to a high cracking temp. in a heating coil and passing the heated oil into a reaction chamber, where sepn. of vapors and liquid occurs. Oil at a lower temp. than that of the condensate oil is introduced into the reaction chamber to lower the temp. of reaction. Liquid is withdrawn from the reaction chamber at a rate adequate to prevent the accumulation of liquid and vapors are withdrawn from the reaction chamber and passed through a plurality of vapor digestion zones wherein the vapors are maintained at cracking temp. to effect further cracking. The vapors in the last digestion zones are scrubbed with condensate oil. Liquid from the last digestion zone is directed to the reaction chamber. The cracked vapors are passed to a fractionating zone and sepd. into a final light distillate and a reflux condensate. The reflux condensate is conducted to the heating coil. Cf. C. A. 27, 1156.

**Conversion of hydrocarbon oils.** Richard F. Trow (to

The Texaco Development Corp.) Can 335,819, Sept 19, 1933 Higher-boiling hydrocarbon oils are converted into lower-boiling oils by subjecting the cycle condensate formed in the process to cracking temp in transit through a heating coil and passing the heated oil into an enlarged reaction zone, wherein cracking temp under superatm pressure is maintained and where sepn of vapors from liquid occurs and the liquid is withdrawn from the reaction zone at a rate adequate to prevent the accumulation of liquid therein. The sep'd vapors are heated in a continued stream to a higher cracking temp than that to which the condensate oil is heated and the heated vapors are put into a second reaction zone, wherein cracking temp under superatm pressure is maintained and sep'n of vapors from liquid occurs. The heat of reaction in the second reaction zone is tempered by introducing fresh charging stock at a relatively low temp. Vapors from the second reaction zone are passed to a fractionating tower maintaining under superatm pressure and sep'd into a final light distillate and a reflux condensate. Liquid is withdrawn from the second reaction zone at a rate adequate to prevent the accumulation of liquid therein and the withdrawn liquid is expanded into a low pressure autogenous distn zone. Evolved vapors are condensed and the condensate directed into the pressure fractionating tower. Reflux condensate is conducted from the pressure fractionating tower to the heating coil as the sole charge thereto.

**Processing hydrocarbon oils** Gu Kaufman and Carl L. Jancia (to The Texaco Development Corp.) Can 335,993, Sept 26, 1933 Cracked motor fuel of high antiknock properties is produced by distilling phenetic crude oil, exp'd therein a lubricating oil fraction containing a substantial amt of high boiling org. acid and subjecting the fraction to vacuum distn in the presence of  $\text{NaOH}$ , thereby producing a heavy still residue composed of heavy hydrocarbon admixed with the Na salts of the high boiling org. acid. The still residue is treated with mineral acid in aqueous solution in sufficient quantity to liberate the org. acids. The mixture is allowed to settle, the gas oil formed during subsequent cracking, to increase the fluidity of the mixture and facilitate settling out of water and suspended solids. The mixture is permitted to settle to form an aqueous layer and an oil layer comprising a mixture of the heavy hydrocarbons and the org. acid. The layer of mixed oil and org. acid is drawn off and cracked under pressure of 250 lb per sq in. or higher and a temp. of over 750° F. The cracked products are fractionated to produce motor fuel. A portion of the relatively high boiling cracked products is returned as a recycle oil for distillation of the acid treated residue.

**Processing hydrocarbon oils** Helge C. Dieckhoff (to The Texaco Development Corp.) Can 335,994, Sept 26, 1933 Relatively high boiling hydrocarbon oil is converted into lower boiling oil of the kerosene type by heating to distn temp in a coil flowing through of oil and discharging the heated oil into a sep'n zone where the oil sep'n into vapor and liquid portions. The vapors are withdrawn and cracked in the vapor phase and the cracked product is discharged into an enlarged coking still. The liquid portion from the sep'n zone is withdrawn and independently cracked in the liquid phase and the product is directly discharged into an independent distn and fractionating zone. Cracked unvaporized residual product in the distn and fractionating zone are separately collected and separately withdrawn and discharged directly into the coking still wherein they are converted to coke by the heat of the vaporous cracked products passed thereto from the vapor phase cracking operation. Relatively cool fresh charging stock is charged into the independent distn and fractionating zone and brought into intimate contact with vaporous products to effect fractional condensation thereof. The resulting mixture of reflux condensate and fresh oil is collected in the distn and fractionating zone and the mixture is withdrawn and passed to the first coil for treatment. Cf. C. A. 27, 5520.

**Fractionating hydrocarbon oil vapors** Wm M. Strat-

ford (to Texas Co.) U S 1,927,652, Sept 19, 1933 Hydrocarbon oil vapors are introduced into a fractionating tower at an intermediate point of the tower, the upper portion of the tower is cooled to effect fractionation of vapors therein, and the resulting condensate is subjected to vaporization at a point within the tower below the point at which the vapors are introduced, an overhead vapor fraction and unvaporized portions of the condensate are separately withdrawn from the tower, and an intermediate cut is separately withdrawn by taking off vapors from a section of the tower intermediate the point at which vapors are introduced and the point at which the condensate mentioned is subjected to vaporization. App is described. Cf. C. A. 27, 1067.

**Condensing and rectifying hydrocarbon oil vapors** Clarence D. Gard (to Union Oil Co. of Calif.) U S 1,920,160, Oct 10, 1932 In a distn process without substantial decompn, heat supplied for vaporization is automatically regulated (in a described app) in accord with the velocity of the vapors flowing to the condensing stage.

**Vapor phase refining of hydrocarbon oils with sulfuric acid** Jacques C. Morrell (to Universal Oil Products Co.) U S 1,930,219, Oct 10, 1932 A refining soln is obtained from the sludge produced in the process, by sep'g the sludge into an oily layer and an aqueous layer containing a substantial portion of a spacing agent such as  $(\text{NH}_4)_2\text{SO}_4$  or  $\text{PhSO}_3\text{H}$  used in the refining, and adding fresh  $\text{H}_2\text{SO}_4$  to the aqueous layer.

**Desulfurizing hydrocarbon oil distillates** Harold C. Weber (to Universal Oil Products Co.) U S 1,930,216, Oct 10, 1932 Distillates such as lower boiling motor fuel fractions are subjected to the simultaneous action of substances such as  $\text{NaHCO}_3$  and  $\text{NaCl}$  capable of producing  $\text{OH}$  and  $\text{Cl}$  ions while in the presence of metallic Ag and metal such as Al electropos. to H.

**Catalytic polymerization of unstable constituents of hydrocarbon oils** Frank W. Hall and James H. Grahame (to Texas Co.) U S 1,930,974, Oct 17, 1932 Vapors from oil such as cracked naphthenes for stable gasoline production are contacted with adsorbent catalytic material such as fuller's earth to polymerize unstable constituent and form liquid polymers with resulting increase in the end point of the vapor. The resulting vapor is introduced to the middle portion of a dephlegmating tower to form a liquid fraction and a desirable dephlegmated vapor fraction and the polymer collected during the contacting of the vapor are introduced to a lower portion of the tower to combine with the polymer liquid fraction being formed and collecting in the lower portion of the tower. The polymers are subjected to a reboiling to form a desirable vapor fraction and a liquid fraction free from the previously admixed volatile fractions and this vapor fraction is passed through the upper portion of the tower along with the incoming contacted vapor to form a final vapor fraction which is removed and condensed (a portion of the distillate being returned as reflux to the tower). App is described.

**Motor fuels** N. A. de Buttsche Petroleum Mitt. Schrupp, Brit 395,192, July 13, 1933 See Fr 712,957 (C. A. 27, 512).

**Motor fuel and lubricant** Union Motors, Brit 394,800, July 6, 1933 Internal-combustion engine fuel oil, gas oil is used also as the lubricant. It is continuously withdrawn from the lubricating system to form in its impure state the whole or part of the fuel charge and is replaced by fresh oil so that the lubricant is maintained in better condition than with normal replacement.

**Gasoline from cracked hydrocarbon vapors** John W. Brown (to Gray Processes Corp.) U S 1,930,453, Oct 10, 1932 For obtaining a stable distillate from cracked hydrocarbon vapors, the vapors are fractionated in a first fractionating stage from which head products are withdrawn, the head product is clay-treated and the polymers formed in the clay treating stage are withdrawn. The clay treated vapors are fractionated in a second fractionating stage from which tail products are withdrawn and mixed with the polymers mentioned and

this mixt. is introduced at selected points in the first fractionating stage. An arrangement of app. is described.

**Treating gasoline.** Jacque C. Morrell (to Universal Oil Products Co.). U. S. 1,930,248, Oct. 10. Deterioration during storage of cracked gasoline having anti-knock properties is reduced by adding about 0.1% of camphor, camphorophorone or camphoric acid.

**Apparatus for purifying gasoline by fuller's earth or the like.** Henry Thomas (to Sun Oil Co.). U. S. 1,929,907, Oct. 10. Structural features.

**Tank for storing hydrocarbon motor fuels.** Audley E. Harmsberger (to Pure Oil Co.). U. S. 1,930,592, Oct. 17. A vent is provided connected with a device through which a liquid such as pyrogallic acid may be circulated in order to absorb O from the entering air. Various structural details are described.

**Apparatus for collecting volatile material evolved from light hydrocarbon oils in storage tanks, etc.** Edwin F. Nelson (to Universal Oil Products Co.). U. S. 1,930,211, Oct. 10. Various structural and operative details are described.

**Apparatus suitable for delivery of fire-extinguishing foam into oil tanks, etc.** Karl Schmidt (to Pyrene-Minimax Corp.). U. S. 1,929,390, Oct. 3. Structural and mech. features of a portable app.

**Mineral oils.** Standard Oil Co. Fr. 748,925, July 13, 1933. Naphthenic and other undesirable compds. in mineral oils are removed by extg. with a chlorinated ether, such as  $\text{ClCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{Cl}$ , or by a mixt. of a primary and a secondary solvent. The secondary solvents used include ketones of low b. p. such as acetone, ethyl methyl ketone, dipropyl ketone, etc., and the primary solvents used have higher b. p. and mol. wt., and include aromatic  $\text{NO}_2$  compds., xylidines, chlorobenzenes, chlorophenols, phenylacetates, halogenated ethers, heterocyclic compds. such as dioxane, piperidine, furfural, thionine, aldehydes and halogenated aliphatic hydrocarbons. The preferred proportions are 1-2 vols. of the primary solvent to 1 vol. of the secondary. Cl. C. A. 27, 2291.

**White mineral medicinal oil.** Seymour W. Ferris (to Atlantic Refining Co.). U. S. 1,928,832, Oct. 3. A viscous mineral oil distillate is extd. with  $\text{PhNO}_2$  to dissolve from the oil a substantial part of its components which react with  $\text{H}_2\text{SO}_4$ . The  $\text{PhNO}_2$  is sepd. from that part of the distillate which remains undissolved therein, and the undissolved portion is treated with a further quantity of  $\text{PhNO}_2$  to dissolve further material reactive with  $\text{H}_2\text{SO}_4$ . After sepn., the undissolved oil is treated with  $\text{H}_2\text{SO}_4$ , the acid sludge is sepd., and the oil is treated with an adsorbent material. A white oil is obtained having a viscosity of at least 500 sec. Saybolt Universal at  $38^\circ$  and a viscosity-gravity const. not higher than 0.803. App. is described.

**Cutting fluids from mineral oils.\*** Roy F. Nelson (to Texas Co.). U. S. 1,929,955, Oct. 10. S is mixed with an oil having a viscosity of at least 70 sec. Saybolt at  $38^\circ$  and the mixt. is heated to a reacting temp. (suitably about  $200^\circ$ ) under a superatm. pressure of about 75-150 lb. per sq. in.

**Refining oils and waxes.** The Burmah Oil Co. Ltd., Geo. R. Nixon and Ronald E. Downer. Brit. 304,414, June 29, 1933. Oil-wax mixts. contg. 5% or more of paraffin wax are refined, prior to sepn. by known processes into wax and oils, by treating the melted mixt. at up to  $180^\circ$  with anhyd. chlorides of Al, Fe, Zn, Sn, Sb and (or) Cr and sepg. the sludge, e. g., by settling, centrifuging and filtering through an absorbent, e. g., fuller's earth, bauxite. The sludge may be treated to recover the chloride and to make asphaltic bitumen. Among examples crude oil, topped to  $300^\circ$ , is agitated 10 min. at  $1.5^\circ$  first with 1% and twice with 2% of  $\text{AlCl}_3$ , the oil is sepd. from the settled sludge, filtered through fuller's earth and distd. under reduced pressure to obtain gas oil, a distillate from which wax scale and lubricating oil

are obtained by pressing and a residue from which viscous oil and crude petroleum are obtained by cold settling with naphtha.

**Separating more and less fusible portions of mineral oil-wax mixtures.** Albert G. Peterkin, Jr. and Lloyd B. Smith (to Atlantic Refining Co.). U. S. 1,929,933, Oct. 10. An alk. silicate soln. in heated condition is used for treating the material to keep the more fusible portions liquid and facilitate sepn. U. S. 1,929,934 relates to use of heated Na silicate soln. for sweating oil and low-melting wax from wax of higher m. p.

**Leaf-type apparatus suitable for filtering wax from chilled oils.** Francis X. Govers (to Indian Refining Co.). U. S. 1,931,000, Oct. 17.

**Purifying crude paraffin.** Martin Mueller-Cunradi and Robert Werner (to Standard-I. G. Co.). U. S. 1,930,468, Oct. 17. The crude material is treated, in liquid state, with a gas comprising  $\text{H}_2$  at a temp. of  $250-400^\circ$  and under a pressure of at least 20 atm. and in the presence of a mixed catalyst contg. at least 2 elements selected from Bi, V and Fe metal, and the temp. and duration of the treatment are so regulated that the paraffin undergoes no substantial cracking.

**Testing lubricating oils.** "Yacoco" S. A. F. Ger. 584,175, Sept. 15, 1933. A relatively small amt. of the oil is circulated between two relatively large surfaces which are in relative motion and sufficiently close together to cause the oil to form a film. The same amt. of fresh oil is then circulated through the app. under a different atm., e. g., an atm. of N, but under otherwise identical conditions. The chem. and phys. properties of each sample of oil are then detd. and compared.

**Dewaxing hydrocarbon lubricating oil.** Robert E. Manley (to Texas Co.). U. S. 1,929,831, Oct. 10. The oil is subjected to a sepg. treatment, while chilled and maintained at a low temp., by which pptn. of wax constituents is effected and while intimately mixed with an inert comminuted solid filter-aid material contg. not more than 5% by wt. of free water comprising a filter aid recovered from a previous operation of dewaxing lubricating oil (the filter-aid material having been chilled to a temp. approx. equal to the temp. of the chilled oil before being mixed with it) so that pptd. wax and filter-aid material are sepd. from the oil. The filter-aid material is subsequently sepd. from the wax for further use in the process. App. is described. Cf. C. A. 27, 2029.

**Dewaxing mineral lubricating oils.** Leo D. Jones (to Sharples Specialty Co.). U. S. 1,930,479, Oct. 17. The wax-contg. oil is treated with a solvent comprising dichloroethane and a petroleum fraction lighter than the oil to be dewaxed, selected and proportioned so that the solvent mixt. will have a sp. gr. greater than that of wax pptd. in the mixt. by cooling. The mixt. is then cooled to effect pptn. of wax and the pptd. wax is sepd., as by centrifuging. An app. is described. Cf. C. A. 27, 594.

**Cleansing used lubricating oils.** Charles E. Fox (to British Oil Cleaners Ltd.). U. S. 1,930,006, Oct. 10. Various details are described of the construction and operation of an elec. heated app. for containing the oil and water and for effecting sepn. of foreign particles of colloidal size from the used oil.

**Rotary device for testing the consistency of liquid materials such as lubricating oils.** Elton S. Stephens (to Consistometer Corp.). U. S. 1,930,629, Oct. 17. Structural and mech. features.

**Asphaltic emulsion.** Donald McK. Hepburn (to Amiesite Asphalt Co. of America). U. S. 1,931,072, Oct. 17. A bituminous compn., ready for application without heating to an unheated aggregate such as paving material, comprises a dispersion in soapy water of asphalt about 296 parts, a non-volatile heavy emulsified oil such as a fuel oil about 20 parts, a salt of a fatty acid having a greater affinity for oils than for water such as Al oleate 1-4 parts and a water-sol. soap about 9 parts.

## 23 CELLULOSE AND PAPER

CARTER, I. CURRAN

**Cellulose XLIX Method of reaction of cellulose**  
**2 Mechanism of the methylation of cellulose fibers**  
 (Formation of a half methylate of cellulose) K. Hess, C. Trogus, W. Lyvick and I. Carthe. *Ann.* 506, 280-85 (1933), cf. (A) 28, 111. Methylation (on soda cellulose II (I) with  $\text{Me}_2\text{SO}_4$  in  $\text{H}_2\text{O}$ ) are reported for 5, 10, 30, 70 and 100%  $\text{Me}_2\text{SO}_4$  at 18°, 35° and 49° over a period of 2 hrs. At 35° and 49° the reaction rapidly attains a steady rate (about 20 min.), while at 18° it gradually increases, finally reaching about 28% MeO in 7 hrs. 5%  $\text{Me}_2\text{SO}_4$  gives 19%, MeO 10%, 6 hrs., 27%, 30%, 37% after 6 hrs., 35%, after 7 hrs., 70%, 36%, after 4 hrs., 34%, after 6 hrs., 100%, 30% after 3 hr. The results indicate at least 2 stages of methylation the 1st of which is the formation of a cellulose deriv. contg. 1 MeO to 2 C<sub>6</sub> groups, this is followed by the formation of a tri Me deriv. Proof of this follows from an x-ray exam. of the reaction product at various stages and of the various fractions of the methylated product. Hydrolysis of the partially methylated fibers and the prepn. of a half-methylate (II) of cellulose I gives II, with 9.11% MeO, in about 10 min. with pure  $\text{Me}_2\text{SO}_4$ . II forms a double compd. with MeOH. Hydrolysis of II gives glucose, 2 methyl and 3 or 6 methylglucose. **L Formation of a uniform diethylglucose from partially ethylated cellulose** K. Hess. *Ibid.* 23, 8. Cellulose contg. 2.5 H<sub>2</sub>O groups (103.2%) in 300 g. AcCl treated with 34.5 g. dry HBr and allowed to stand 24 hrs. at 0° gives 40 g. of a bromoacetate diethylglucose in 12% yield, 257 (C<sub>12</sub>H<sub>21</sub>) the Br atom is probably on C<sub>1</sub> since it is easily removed by Ag<sub>2</sub>CO<sub>3</sub> the Ac group is probably on C<sub>4</sub> but the position of the H<sub>2</sub>O groups is unknown. **LI Esterification of cellulose with tosyl chloride in the presence of pyridine** K. Hess and N. L. Smith. *Ibid.* 507, 62-9. Cellulose and p.  $\text{Me}_2\text{SO}_4$  (I) in  $\text{C}_6\text{H}_5\text{N}$  at 70° for 13 days give a product contg. about 11% S, 12% Cl and 1% N which is a complicated mixture. A product contg. 12.42% S, 7.84% Cl and 0.8% N warmed with  $\text{C}_6\text{H}_5\text{N}$  in  $\text{C}_6\text{H}_5\text{N} \cdot \text{HCl}$  at 0° for 2 days gives a product with 11.6% Cl, 1.4% S and 3.6% N. Cu rayon, shaken with  $\text{I}_2$  in  $\text{C}_6\text{H}_5\text{N}$  4 days at 15° 20° gives a product contg. 2 tosyl groups and with only 0.1% Cl and 0.7% N. The tosyl group is difficultly removed and with partial decomposition of the cellulose. The action of  $\text{NH}_3$  or  $\text{H}_2\text{N} \cdot \text{NH}_2$  does not increase the N content above 2%. C. J. West.

**A new method for the determination of cellulose, based upon observations on the removal of lignin and other incrusting materials** Arthur C. Norman and Samuel H. Jenkins. *Biochem. J.* 27, 815-31 (1933). The cellulose is a polysaccharide material associated with pure cellulose must remain intact in any satisfactory method of cellulose determination. The method proposed for raw and wood cellulose involves first 2 treatment with neutral hypochlorite and then 3 or more with acid hypochlorite, each followed by boiling with Na sulfite. Benjamin Harrow.

**Some factors relating to the estimation of  $\alpha$  cellulose** Adoni Yogananda Swamy and Frank W. Bailey. *Cellulose Paper Trade J.* 99, 1331-8, 1576, 1578, 1611-18, 1651-4, 1692 (1933). *Paper Maker & Brit. Paper Trade J.* 85, 119-24 (1933). From a critical review of outstanding methods proposed for the determination of  $\alpha$  cellulose, it is concluded that the U. S. Bureau of Standards method is simple, rapid and accurate for practical application.  $\text{CO}_2$  present in the air has little or no effect on the results. Atm.  $\text{O}_2$  is absorbed by the alkali pulp mixture during mercerization, but the amt. of oxycellulose so produced, even after 24 hr., is too small to be detected by the  $\alpha$  cellulose determination. The use of an oven dried (104°) sample for the determination is wrong in principle because during the heating, degradation of the cellulose occurs. This occurs on a second mercerization. The effect of (1) mercerization, extruding the etherification (2) etherification, the

the drying of the  $\alpha$  cellulose by heat, (b) being the more important. Degradation occurring when a cellulose material is heated at about 100° is due mainly to the agency of atm.  $\text{O}_2$ , the non-cellulosic injurious chemical impurities present in pulp do not cause the entire degradation, as is generally believed by those engaged in testing the permanence of paper by artificial aging. Cellulose damaged during bleaching usually suffers a very pronounced degradation during heating. The order of the pulps tested arranged according to their ability to produce permanent papers would be, according to the artificial aging test in air: Kraft, nitrating alpha, paper alpha, sodium pulp, strong sulfite, Al sulfite, L. B. sulfite A. The tech. interest of the  $\alpha$ -cellulose detn. of the present investigation is pointed out. A. Papineau-Couture.

**State of cellulose compounds in solution I Rotatory power of cellulose acetate** J. Duclaux and Mme. A. Dobry. *Bull. Soc. chim.* 53, 724-5 (1933). The rotatory power of cellulose acetate in 13 different solvents was independent of the concn. in the range studied (0.5 to 10%), and there was no correlation with the properties of the solvent. The detn. of the rotatory dispersion based on the application of Lowry (C. 4, 15, 389) and Darnows (C. 1, 17, 970) indicated that the solvents caused deformation (condensation or internal isomerism) of the cellulose acetate mols. with a resulting equil. of 2 forms, d- and l-rotatory, of the acetate in proportions varying from one solvent to another. I. A. Sammonds.

**Cellulose fibers of a low degree of acetylation** A. Lerner. *Ibid.* 11, 667-77, 613-51, 723-9 (1933). An address discussing the prepn. and properties of cellulose monoacetate fibers. *Cell.* 525 (1934), (A) 25, 4136, *Cell.* 525 (1934), (A) 25, 5, 01, *U. S.* 1,861,200, (A) 26, 910. The mechanism of their behavior toward the various classes of dyes, their advantages and applications. A. Papineau-Couture.

**Weakly acetylated fiber celluloses** A. Lerner. *Ingénieur chim.* 46, 67-81 (1933). The prepn. and properties of weakly acetylated fiber celluloses, then dyeing properties together with those of other fiber celluloses and their applications in dyestuffs. Photomicrographs of dyed sections and acetylation curves are presented. Twenty-two references. K. K.

**Dyeing cellulose materials with reference to the structure of cellulose** R. I. Rose. *Ind. Eng. Chem.* 25, 1408-15 (1933), cf. (A) 26, 2509. Since different cellulose materials as well as derivatives react differently toward the same dyestuff and since much treatment of a given material alters its dye index, probably correlation relevant to the structure of cellulose can be found. I. A. Sammonds.

**The structure of cellulose gel V The structure of natural cellulose fiber revealed by x-ray analysis** Katamitsu Atsuki and Masanori Ishiwara. *J. Soc. Chem. Ind. Japan* 36, Suppl. banding, 21 (1933), cf. (A) 27, 1401. X-ray analyses of cotton and hemp fibers were made and compared with the structure of artificial silk and other cellulose gels. Experimental results are reported. **VI The structure of viscose silk and Cellophane analyzed by x-ray** *Ibid.* 521-4. The structure of cellulose gels in the form of viscose silk and Cellophane, regenerated from viscose, was determined by x-ray analysis. X-ray patterns are reproduced. Karl Kummermeyer.

**The properties of oxycellulose and the methods for its determination** R. Haller and Fritz Lorenz. *Bull. Federation intern. assoc. chim. textile couleur* 1, 16 (1933). A review of the literature. It is concluded that none of the published methods of identifying oxycellulose is so far this compound. Oxycellulose is a mixt. of compounds whose composition depends on the history of the sample and consequently it cannot be identified by a general method. S. Leiber.

**Holocellulose, total carbohydrate fraction of extractive free maple wood** Geo. J. Ritter and F. J. Kurth.

*Ind. Eng. Chem.* 25, 1250-3 (1933).—A new rapid method for isolating the total carbohydrate portion of extractive-free wood is described. The name "holocellulose" is proposed for this material replacing "Skallettsubstanzen" coined by Schmidt, Tang and Jandabeur, *C. A.* 26, 1772.

F. A. Simmonds  
**Limits of fractionation of nitrocelluloses.** J. Duclaux and J. Barbieri. *Bull. soc. chim.* 55, 584-5 (1933).—The viscosities of 4 fractions obtained by fractional pptn. of a nitrocellulose increased to a limiting value corresponding to a definite compd. The chem. compn. of the last fraction was the same as that of the initial compd. and the soly. was not appreciably modified. F. A. S.

**Lignin. X. Identity and structure of spruce lignins prepared by different methods.** Fritz Brauns and Harold Hibbert. *J. Am. Chem. Soc.* 55, 4720-7 (1933); cf. *C. A.* 27, 2803.—Lignin has been isolated from spruce meal by the action of glycol and HCl, the use of MeOH and HCl, extn. with PhOH and HCl, Willstätter's method and Freudenberg's method. The lignin isolated in each case was subjected to careful purification, and well-characterized derivs. of each type were prepd. by methylation and acylation, resp. Each lignin type yields a well-characterized lignin-phenol condensation product, the analysis of which shows that they are derived from a common lignin building unit. This building unit, representing the native lignin present in spruce wood, has the empirical formula  $C_{10}H_{10}O_6$  or  $C_{10}H_{10}O_6(OH)_2(OMe)_2$ . Of the 5 free HO groups at least 3 are aliphatic in character, while 1 is of an acidic type, either phenolic or enolic; the 5th HO group differs markedly from the remaining 4 and is characterized by its reactivity toward alkylating reagents such as HCl and alcs., phenols, etc. The phenol condensation products from Willstätter and Freudenberg lignin are shown to possess the structure  $C_{10}H_{10}O_6(OH)_2(OMe)_2(OPh)(C_6H_4OH)_2$ . C. J. W.

**Formaldehyde-yielding complex in the lignin molecule.** Pulin Behari Sarkar. *Current Sci.* 2, 93 (1933).—Raw jute freed from fatty material when distd. with 12% HCl yields furfural (I) and HCHO (II). Jute after complete removal of lignin by moist  $ClO_2$  gives I but not II. Lignin obtained by 72%  $H_2SO_4$  or Willstätter's method gives II but not I. Raw bamboo similarly treated gives II but not delignified bamboo. Rachel Brown

**Investigations on viscose by G. Kita and co-workers.** XLVII. Quantitative investigation of the time-temperature relationship of the aging of alkali cellulose. S. Iwasaki and T. Sakuno. *J. Soc. Chem. Ind., Japan* 36, suppl. binding 507-11 (1933); cf. *C. A.* 27, 1747.—Two types of fibers were subjected to aging expts. varying from 1 hrs. to 216 hrs. and from 13° to 25°. After aging the regenerated cellulose was changed to cellulose nitrate, and the viscosities were detd. on the acetone solns. The aging effect upon viscosity was evaluated in terms of  $K = \log \eta / C$ , where  $\eta$  is the relative viscosity and  $C$  the concn. of the solu. The exptl. data resulted in families of straight lines when  $K$  is plotted against  $\log Z$ , where  $Z$  is the time of aging. Further correlation gave an expression for the relative viscosity  $H$ , when  $C = 1$ ;  $H = K_1 K_2 Z^\theta$ ;  $K_1$  and  $K_2$  are consts. characteristic of one or a no. of cellulose types resp.,  $\theta$  is the aging temp. and  $n$  the slope of the family of curves in the  $K - \log Z$  plot. Karl Kammermeier

**The cooking process. IV. Cooking wood with sodium thiosulfate.** S. I. Aronovsky and Ross A. Gortner. *Ind. Eng. Chem.* 25, 1200-5 (1933); cf. *C. A.* 27, 3072.—A comparison of the pulping effects of  $Na_2S_2O_3$  and water on aspen sawdust showed the  $Na_2S_2O_3$  removed more lignin and  $\alpha$ -cellulose and less pentosans and Cross and Bevan cellulose than the water alone. F. A. Simmonds

**Alkaline process for obtaining high yields of pulp from aspen wood.** Roy L. Davis. *Paper Trade J.* 97, No. 8, 44 (1933).—A process of soda cooking, consisting of alkali digestion with low percentage and concn. of alkali followed by a 1st-stage chlorination, an alk. wash, and a final hypochlorite bleach, gave favorable results. Yields of about 50% bleached pulp based on the wood may be obtained where a rod mill is available for intermediate

refining, or of 53-54% where a rod mill is not available; the bleach consumed by these 2 types of cooks is 30 and 20%, resp. This compares with a 42-45% yield of bleached pulp and a bleachability of 8-10% by the com. soda process. Black liquor may be used to make up the cooking liquor vol. without any appreciable ill effect on the pulp. The results obtained by the use of typical dil. kraft liquor, consisting of 2 parts NaOH to 1 part  $Na_2S$ , were no better than those obtained by the use of dil. NaOH. Two-stage bleaching, with Cl in the 1st stage followed by an alk. wash and completion of bleaching with hypochlorite, is beneficial mainly in saving about 33% of the total Cl consumption. Yields as high as the above cannot be obtained by the use of concd. liquor and shorter cooking time. The chem. tests on the pulps obtained by the proposed process are as good as those on com. pulps, the bursting strength is 50-100% higher, and the tearing strength also is higher. The proposed process is much more efficient in preserving the cellulosic portion of the pulp than com. pulping procedure. The opacity of the unbeaten pulp is about the same as that of com. pulps; when beaten, the com. pulps, which do not hydrate readily, have a greater tendency to retain their unbeaten opacity. A. Papineau-Couture

**The relation between sheet strength and sizing of unbleached sulfite pulp.** H. Ellern-Bichmann. *Papier-Fabr.* 31, Tech.-wiss.-Teil 197-201, 209-13, 222-6 (1933).—Rosin size effects a partial coverage of the fibers with relatively rough particles. In unbeaten pulps the natural adhesion of the fibers is small, and the rosin reinforces it. If the natural adhesion is large, as in highly beaten stuffs, the rosin decreases it by interference with interfiber bonding. This appears to explain the results of numerous expts. An optimum sheet strength is developed with 1-1.5% rosin and 1 3/4% alum, depending on the degree of beating. Larger amts. cause a rapid decrease of strength. The deleterious effects of alum, of which the fiber may absorb as much as 6%, can be largely avoided if the rosin is well beaten into the fiber. The loss of strength due to alum can be more than compensated by the use of 3-5% glue size; hence the effect of alum must be on the interfiber, not on the intrafiber, bonds. Pine oil, contrary to experience in the textile industry (cf. Fermazin, *C. A.* 25, 5983), has no strengthening effect on paper. Thorium and cerium salts give as good sizing as alum, and being nonamphoteric, cannot impart acidity to the sheet. Heating sized sheets to 150° while wet, but not under tension, has no serious effect on the sizing; improperly sized sheets are improved by high temp., but properly treated sheets develop the full sizing effect at 70°. Because of the harmful effect of alum, hard water should be neutralized with acid under careful pH control, and only enough alum added properly to set the size. The relative amt. of glue size retained by fibers under standard conditions is set up as a measure of the adhesive power of the fibers. It is independent of the degree of fibrillation and fiber swelling, actually decreasing somewhat at high beating degree. This is contradictory to the theory that adsorption by fibers is a measure of fibrillation and hydration. R. H. Doughty

**The influence of moisture and temperature on the strength and elasticity of paper.** A. Basberg. *Papier-J.* 21, 103-5, 114-17, 123-6, 130-9 (1933).—Theories of paper strength are discussed. The strength of paper reaches the max. at 50° and decreases with further heating. At a const. temp. of 20° the max. is attained at 1-2% moisture. At const. temp., elasticity is practically independent of the moisture of the paper. When a load is applied in the Schopper tester, the strip shows permanent elongation or "slip" before rupturing. This "slip" does not increase with time. Paper heated for some time at 100° will not recover its original moisture content. The higher the heating temp. the less moisture is reabsorbed. This permanent loss of moisture is accompanied by a permanent loss of strength. Clinton L. Brooke

**Clay-casein slips for paper coating. Causes and prevention of foaming.** E. O. Whittier, S. P. Gould and S. A.

Hall. *Ind. Eng. Chem.* 25, 1213 16(1933); cf. *C. A.* 27, 4392.- The theory is advanced that the foaming tendency of a casein is dependent upon the degree of aggregation of the casein mols. Pptn. of the curd at or above 34° with slow agitation and immediate washing yielded a casein of low foaming index. Surface-tension depressants added during pptn. of the curd were effective in preventing foaming. Likewise, the addn. of a casein of low foaming index to one of high index prevented foaming. W. A. Moore

Siberian larch (Gordon) 22. Printing on articles of regenerated cellulose (U. S. pat. 1,929,394) 26

Waterproofing thin films of regenerated cellulose. Wolf & Co., Komm.-Ges. auf Aktien, Emil Czapek and Richard Weingand. *Ger.* 683,117, Aug. 29, 1933. The films are washed in the usual way and the water left in the films is then displaced by a water-sol. cellulose ester solvent, after which the films are coated in known manner with a cellulose ester lacquer.

Halogen-containing cellulose ethers. Henry Dreyfus. U. S. 1,930,471, Oct. 17. An ether such as a bromo-ethyl cellulose ether is produced by treating cellulose, in the presence of a base such as NaOH in an aprot. and concn. reactive with the cellulose, with a halogen-contg. etherifying agent such as ethylene chlorobromide or the like. U. S. 1,930,472 relates to the production of halogen hydroxy alkyl ethers of cellulose such as cellulose chlorohydroxy propyl ether by treating cellulose, in the substantial absence of alkali, with an etherifying agent contg. in addn. to the etherifying radical a halogen atom of lower reactivity than the etherifying radical, such as epichlorohydrin.

Esterifying cellulose. Robert Haller and Andreas Rupert (to Soc. pour l'ind. chim. à Bâle). U. S. 1,930,895, Oct. 17. For esterifying cellulose while maintaining its structure, material such as cotton or "viscose silk" is treated with an aliphatic acid anhydride such as  $\text{Ac}_2\text{O}$  in the presence of a K salt of a weak acid such as  $\text{KOAc}$  in the absence of an acid catalyst.

Cellulose ester composition suitable for films or sheets, etc. Hans T. Clarke and Charles F. Waring (to Eastman Kodak Co.). U. S. 1,930,142, Oct. 10. A cellulose ester such as cellulose acetate is used with a plasticizer comprising phenyl- or *o*-cresyl-*p*-chlorobenzoate or phenyl 3,4-dichlorobenzenesulfonate.

Cellulose ester products. I. G. Farbenind. A.-G. (Delft Dells and Albert Brucke, inventors). *Ger.* 584,179, Sept. 26, 1933. An azole compd., capable of coupling with a diazo compd., is added to a cellulose ester soln. from which artificial fibers or films are then made in known manner. Fibers or films which can be dyed by treatment with a diazo compd. are obtained. Suitable enolic compds. are  $\beta$ -naphthol, 2,3-hydroxynaphthol anilide and 1-phenyl-3-methyl-5-pyrazolone.

Cellulose derivatives. Henry Dreyfus. *Brit.* 394,722, July 6, 1933.

Cellulose derivatives having strong affinity for acid dyes. Robert Haller and Alphonse Heckendorn (to Soc. pour l'ind. chim. à Bâle). U. S. 1,929,868, Oct. 10. By treating cellulose with alkali and  $\text{CS}_2$ , then (preferably in the presence of an excess of the  $\text{CS}_2$  as a reaction medium) with phosgene, thiophosgene, S chloride, chloro-carbonic esters,  $\text{AcCl}$  or the like, and then effecting further conversion of the product with an aliphatic diamine such as piperazine cellulose derivs. are obtained which retain the original fibrous structure of the cellulose, e. g., cotton, but contain S and N and have a strong affinity for acid and direct dyes.

Processing cellulose derivatives. Camille Dreyfus and Herbert Platt (to Camille Dreyfus). *Can.* 335,671, Sept. 12, 1933. Yarns, filaments, bristles or fabric contg. org. esters of cellulose are stiffened by the action of  $\text{H}_2\text{SO}_4$  of a strength between 40 and 80% for 5-30 sec. After treatment the  $\text{H}_2\text{SO}_4$  is removed by washing with water and treatment with weak alk. soln. such as weak solns.

of NaOH or  $\text{NH}_4\text{OH}$ . If the org. ester material is partially sapond. the action of the strong  $\text{H}_2\text{SO}_4$  is not as great, so that the stiffness imparted is not as great. The stiffness may be controlled by partial sapon. of the material before the treatment with  $\text{H}_2\text{SO}_4$ .

Compositions containing cellulose derivatives. I. G. Farbenind. A.-G. (Hans Persiel, inventor). *Ger.* 584,166, Sept. 15, 1933. See U. S. 1,885,475 (*C. A.* 27, 1169).

Partially acetylated cellulose. Cyril J. Staud and Russell H. Van Dyke (to Kodak Ltd.). *Brit.* 394,359, June 23, 1933. Natural cellulose in the form of paper, threads, etc., is partially acetylated in a bath comprising an acetylating agent and a non-solvent for cellulose triacetate. The amt. of acetylating agent used, may be insufficient for the production of triacetates, or a normal amt. may be present, in which case the time, temp. and (or) strength of soln. are insufficient for complete acetylation.  $\text{CCl}_4$ ,  $\text{C}_6\text{H}_6$  and toluene are suitable non-solvents. The products have high elec. resistance and may be used in the production of insulated wires or as dielectrics in condensers and transformers.

Acetone-soluble cellulose acetate. Thomas F. Murray, Jr., and Harry LaB. Gray (to Eastman Kodak Co.). U. S. 1,930,145, Oct. 10. Cellulose such as cotton linters is pre-treated in a concd. org. acid such as glacial  $\text{HIOAc}$  in the presence of an acetylation catalyst such as  $\text{H}_2\text{SO}_4$  and  $\text{H}_3\text{PO}_4$ , and acetylation is effected by adding  $\text{Ac}_2\text{O}$  and at least 25 cc. of an aldehyde such as acetaldehyde per 100 g. of cellulose employed, which serves to produce an acetone-sol. product. Cf. *C. A.* 27, 4395.

Decolorizing dyed cellulose acetate scrap. Marvin J. Reid (to Eastman Kodak Co.). U. S. 1,930,133, Oct. 10. Dyed sheet scrap material is dissolved in acetone, the soln. thus formed is passed into an excess of water, and the resulting cellulose acetate ppt. is treated while in a relatively open and porous condition with an aq. Cl-contg. bleaching agent.

Use of propylene chloride and ethyl lactate, etc., as solvents with cellulose acetate. Henry B. Smith (to Eastman Kodak Co.). U. S. 1,930,134, Oct. 10.

Plasticizers for esters such as cellulose acetate. Henry B. Smith and Stewart J. Carroll (to Eastman Kodak Co.). U. S. 1,930,135, Oct. 10. Butyl-*o*-methoxybenzoate, ethyl *p*-methoxybenzoate or propyl *p*-hydroxybenzoate are used as plasticizers.

Use of furfural diacetate and *p*-nitrobenzyl acetate as plasticizers for esters such as cellulose acetate. Henry B. Smith (to Eastman Kodak Co.). U. S. 1,930,136, Oct. 10.

Sugars. Holzhydryl A.-G. *Fr.* 729,295, July 21, 1933. Vegetable materials having a high content of pentosans are transformed to sugars by treating them first with hot moderately dil. acids, e. g., 12-30%, and at temps. near the b. p. of the aq. solns. The greater part of the pentosans are thereby converted to a sol. form, and the hexosans contained in the residues are saccharified in known manner. The reaction may be carried out in a battery of reaction vessels so that the soln. of pentoses becomes more concd. in each. The hexoses and pentoses are polymerized by treatment with a concd. acid soln. The  $\text{AcOH}$  formed in the digestion of the pentoses and hexoses is used in the decompn. of more cellulose.

Films. J. P. Bemberg A.-G. *Brit.* 395,251, July 13, 1933. Films obtained by extruding cellulose solns. into a coagulating bath are brought together before they are completely coagulated and subjected jointly to further treatments. The incompletely coagulated films may be brought also into contact with a finally formed flat structure, e. g., of a woven, knitted or braided fabric, metal, wood, paper, etc. App. is described.

Films, etc. Karl Lorch, Jr., and Erwin Farr. *Brit.* 394,714, July 3, 1933. Transparent films, sheets, artificial glass, etc., are obtained by spreading viscose in a thin layer on a continuously advancing support, completely drying the film produced and then washing with boiling  $\text{H}_2\text{O}$ . The use of pptn., hardening and other treatment baths having a corrosive action on the app. used is thus

avoided. The products may be provided with a metallic or textile fabric reinforcement.

**Treatment of films and sheets.** I. G. Farhenind. A.-G. Brit. 395,243, July 13, 1933. Sheets or films of highly polymeric colloids, particularly cellulose derivs. and albuminous substances, are subjected to extn. with an indifferent non-aq. liquid that has only a feeble swelling action and contains no softening agent for the colloid until the solvent and any softening agent retained by the sheet after manuf. are (almost) completely removed. Among examples (1) a film made from a soln. contg. nitrocellulose, camphor,  $\text{Et}_2\text{O}$  and alc. is extd. with  $\text{Et}_2\text{O}$  and (2) a gelatin film is extd. with  $\text{MeOH}$ .

**Plastic sheeting, etc.** Du Pont Viscoid Co. Brit. 393,957, June 12, 1933. Sheets of cellulose esters and others are obtained from compns. contg. the cellulose compd. in relatively high concns. with a solvent by heating and extruding under pressure through a sheet-forming orifice, cooling the sheet and applying tension thereto as it emerges from the orifice. The extrusion temp. is preferably at least  $45^\circ$  and that of the hardening gas, e. g., air, or liquid, e. g., an aq. soln. of  $\text{EtOH}$ ,  $\text{MeOH}$ , glycerol, sucrose, dextrose, chlorides, sulfates,  $\text{H}_2\text{SO}_4$  or  $\text{H}_3\text{PO}_4$ , preferably  $0-40^\circ$ . In an example pyroxylin is mixed with camphor,  $\text{EtOH}$  and monomethyl ether of ethylene glycol and, after filtering, heated and forced into aq. glycerol, the extruded sheet being subjected to tension and passed through a further bath and then subjected to warm circulating air for a few days. Smooth sheets for making laminated glass or, by working at higher speeds, rougher sheets for phonographs, may be obtained. App. is described.

**Apparatus for coating sheets, films or webs such as those of regenerated cellulose.** Waldemar Schwalbe and Otto Herrmann (to DuPont Cellophane Co.). U. S. 1,930,666, Oct. 17. Structural and mech. details.

**Hollow filaments, etc., of cellulose or its derivatives.** Lonza Elektrizitätswerke und chem. Fabriken A.-G. Ger. 583,272, Aug. 31, 1933. Hollow filaments and other tubular articles of cellulose or its derivs. are perforated at a no. of places, in order to facilitate dyeing and other liquid treatments.

**Artificial threads from viscose.** Thomas F. Banigan (to DuPont Rayon Co.). U. S. 1,931,245, Oct. 17. The threads are bleached, on Al carriers, by use of a hypochlorite bleaching soln. contg. a sufficient amt. of Na bicarbonate to inhibit the corrosion of the carriers by the hypochlorite.

**Artificial threads from viscose.** Harold H. Parker (to DuPont Rayon Co.). U. S. 1,931,266, Oct. 17. In treating viscose threads on Al carriers, with a desulfurizing soln. such as Na sulfide, sufficient Na silicate is added to prevent corrosion of the Al (the total alkali of the soln. being sufficient to prevent the pptn. of silica).

**Artificial filaments from viscose.** Wm. Harrison. U. S. 1,930,803, Oct. 17. The viscose is coagulated in the form of filaments in acids of a hydron concn. less than that of 7%  $\text{H}_2\text{SO}_4$  and after the viscose has entered "a evanescent active plastic state" the filaments are passed into a bath of water to which have been added substances such as  $\text{Na}_2\text{SO}_4$  or glucose which permit the swelling of the formed filaments by the action of the water without effecting their soln. The filaments are treated before complete decompn. of the viscose. An arrangement of app. is described.

**Artificial thread by the "bucket process."** Paul E. Harrison and Wm. V. Sternberger (to Du Pont Rayon Co.). U. S. 1,930,510, Oct. 17. Thread such as that formed from viscose is wound in a coverless bucket rotated at such a speed that the peripheral speed of the winding-on surface at the beginning of the winding operation is in excess of 9100 ft. per min., in order to facilitate the process.

**Artificial threads, films, etc.** Leon Lilienfeld. Brit. 393,941, June 14, 1933. In producing artificial threads, coatings, sizings, dressings, etc., from compds. obtained by reacting cellulose in either order or simultaneously

with a xanthating agent and a reagent such as an etherifying agent which replaces 1 or more H atoms of the OH groups of the cellulose mol. by an org. group or radical 1 or more substances that lead to the production of materials of a semi-lustrous or dull appearance or of materials having hollow spaces dispersed through them are incorporated during the course of manuf. Such substances are  $\text{BaSO}_4$ , Ti salts, animal, vegetable or mineral oils, fats, soaps, aromatic hydrocarbons or derivs. thereof, org. bases, e. g.,  $\text{PhNH}_2$ , or other natural or synthetic substance known to produce delustering of viscose rayon, a gas or substance that evolves a gas in the coagulating step or very finely divided liquid or solid which is afterward removed by evapn. under such conditions as not to damage the material or by extn. with a solvent.

**Filaments, films, etc.** Henry Dreyfus. Brit. 394,015, June 19, 1933. Threads, etc., are produced by dry or wet spinning processes from solns. contg. cellulose esters or ethers, e. g., cellulose acetate of 52-62.5% Ac content, and methylene ethylene ether (I), which may be the sole solvent or present in mixt. with other solvents and (or) diluents. The solns. may contain dyes, pigments, substances reducing inflammability, etc. In a modification I is used to diminish the tendency of fabrics to slip, split or ladder, to improve the pliability, extension or knotting properties of filaments or threads and to assist in the absorption of various liquid and solid materials for dyeing, printing, discharging, loading, re-lustering and delustering purposes. I may be used in making up sizes for textiles. Among examples (1) cellulose acetate fabric is printed with a paste contg. dye or pigment, diethylene glycol,  $\text{H}_2\text{O}$ , I and gum arabic and (2) an  $\text{Me}_2\text{CO}$  soln. of cellulose acetate is spun into a soln. of I. In 394,016, June 19, 1933, divided on 394,015, the filaments, etc., are treated with media contg. I and subjected to stretching operations.

**Cellulose acetate yarns.** Camille Dreyfus and Wm. Whitehead (to Celanese Corp. of America). U. S. 1,930,230, Oct. 10. A soln. of an org. cellulose ester such as cellulose acetate in a solvent such as acetone together with 5% or less of alc. is used for forming yarns or films. The alc. serves to produce a product resistant to delustering. Cf. C. A. 27, 4398.

**Rayon.** Rene Picard (to Du Pont Rayon Co.). U. S. 1,931,239, Oct. 17. For producing an artificial thread having a luster similar to mother-of-pearl, a viscose soln. having a cellulose content of over 7.5% is prepd. from cellulose having an original high  $\alpha$ -cellulose content, the viscose soln. being ripened for a comparatively short period and spun into a bath contg. 100-150 g.  $\text{H}_2\text{SO}_4$  per l. together with at least twice as much sulfate such as  $\text{Na}_2\text{SO}_4$  and  $\text{ZnSO}_4$ .

**Rayon.** British Bemberg Ltd. Brit. 394,217, June 22, 1933. In the wet treatment of rayon the filaments are led round a continuous cylindrical surface and advanced in a helical path and are treated with liquid which is also advanced on the cylinder's surface in a helical path. App. is described.

**Rayon.** I. G. Farhenind. Brit. 395,216, July 13, 1933. In spinning rayon fluctuations of pressure are avoided by the insertion in the discharge pipe of a length of rubber tubing having a bore less than the thickness of the wall. Undue distension of the tube may be prevented by an outer tube or spiral.

**Rayon, etc.** Leon Lilienfeld. Brit. 393,932, June 12, 1933. The processes described in Brit. 335,906 (C. A. 25, 1995), 335,993 (C. A. 25, 1994), 341,843 (C. A. 25, 4126), 341,930 (C. A. 25, 4402), 357,527 (C. A. 26, 6137), 357,540 (C. A. 26, 6137) and 375,334 (C. A. 27, 4080) are modified by using as the coagulating bath a liquid consisting of or contg. a large proportion of an ester of a polybasic inorg. acid and an aliphatic or aromatic monohydric or polyhydric alc., or a sulfonic acid of an aromatic or aliphatic hydrocarbon, or an aromatic sulfonic acid contg. N, or a carboxy organo-mineral acid, or strong  $\text{H}_2\text{SO}_4$ , contg.  $\text{CH}_3\text{O}$  or pyridine, or  $\text{H}_2\text{SO}_4$  of less than 35% contg., and preferably satd. with,  $\text{NH}_4\text{HSO}_4$ . Examples of these baths are  $\text{MeHSO}_4$ ,  $\text{EtHSO}_4$ , mixts.

of MeOH or EtOH with concd.  $H_2SO_4$ , glycerophosphoric acid, glycerolsulfuric acid, a mixt. of acetaldehyde-sulfonic acid and  $H_2SO_4$ , benzenesulfonic acid, sulfonodiacetic acid, sulfoacetic acid, Me or Et sulfonic acid, methionie acid, a sulfonic acid of mineral oil, diphenylaminodisulfonic acid, etc. Mineral acids, inorg. salts, aldehydes, PhNH<sub>2</sub>, pyridine, glycerol, glucose and alcs. may be added to the baths.

**Rayon, etc.** Henry Dreyfus. Fr. 750,640, Aug. 14, 1933. The properties of filaments, threads, etc., made of cellulose esters or ethers, are improved by submitting them, in the form of a chain or sheet, to a drawing operation applied to the entire sheet. Fr. 750,641. A compd. of B is incorporated in cellulose acetate or other org. ester of cellulose used for making filaments, films, etc. The B compd. may be incorporated in the spinning soln. or in the finished product. An org. borate may be used which is afterward decomposed by water or aq. agents.

**Spinning pot for rayon.** Algemeene Kunstzijde Unie, N. V. Ger. 583,335, Sept. 1, 1933.

**Centrifugal spinning pots for artificial filaments.** Algemeene Kunstzijde Unie, N. V. Brit. 394,922, July 6, 1933.

**Combined wet- and dry-spinning apparatus for rayon.** Otto Hansen. Ger. 583,418, Sept. 4, 1933.

**Filtering device for rayon spinning jets.** Kirklees Ltd., Arthur Bennett and Wm. Tong. Brit. 395,051, July 13, 1933.

**Apparatus for producing artificial filaments such as rayon, horsehair, staple fiber, etc.** Leonard J. Shone. Brit. 394,049, June 22, 1933.

**Eliminating gases from "viscose silk" cakes or cheeses.** Jan Koostra (to American Finka Corp.). U. S. 1,930,302, Oct. 10. Air or other harmless gas at a temp. of 50-80° is passed, for a period of about 10 min., through the walls of the spun cakes or cheeses before washing and skinning. App. is described.

**Artificial bristles.** Camille Dreyfus. Wm. Whitehead and Henry W. Kuhl (to Celanese Corp. of America). U. S. 1,930,220, Oct. 10. Heavy stiff artificial filaments having a denier above 25 and which are formed with entrant angles or cusps contain a cellulose deriv. such as cellulose acetate and a resin such as toluene sulfonamide-formaldehyde resin.

**Treating pulp for paper manufacture, etc.** Mone R. Isaacs. U. S. 1,929,432, Oct. 10. A cellulose pulp is beaten in liquor contg. a protein material such as casein,  $Ca(OH)_2$ , and a fluoride such as NaF in order to produce a water-resistant product. Soap and a light mineral oil also may be added.

**Centrifugal machine for purifying paper pulp, crude starch, etc.** Gustav ter Meer. Brit. 394,811, June 6, 1933.

**Treating wood, fiberboard, etc.** Ernest F. M. Payne. Brit. 394,019, June 22, 1933. Wood, fiberboard, wood pulp, wood fiber and fibers contg. lignocellulose, *e. g.*, jute, hemp, are treated successively with a soln. of an acid phosphate of a metal forming an insol. phosphate, *e. g.*, Ca, Mg, Al, Zn, Fe, Cr, and with a soln. that reacts with the acid phosphate to ppt. an insol. phosphate within the cell walls of the material. Thus a Zn phosphate that is resistant to fire and to animal and vegetable life may be applied by soaking the material in a soln. of an acid phosphate of Zn and then in a soln. contg.  $NH_4H_2PO_4$  and (or)  $(NH_4)_2HPO_4$ . The soln. of Zn may be prepd. by dissolving 8 parts ZnO in 39 parts  $H_2PO_4$  (sp. gr. 1.5) and diluting to 100 parts with  $H_2O$ . After pptn. the product may be treated with a soln. of Na aluminate and (or) silicate with or without the addn. of colloidal substances, *e. g.*, carrageen, cellulose solns., viscose.

**Paper-making apparatus.** Wm. H. Millsbaugh. U. S. 1,930,104, Oct. 10. Structural and mech. features.

**Paper-making apparatus.** James K. Darby (to Wm. H. Millsbaugh). U. S. 1,931,062, Oct. 17. Mech. features.

**Device for feeding paper stuff to the wire cloth of a paper-making machine.** Firma J. M. Voith. Ger. 583,291, Aug. 31, 1933.

**Flow-boxes for paper-making machines.** Walter Voith, Hermann Voith and Hanns Voith (trading as the firm J. M. Voith). Brit. 395,539, July 20, 1933.

**Means and method for removing press-rolls from paper-making machines.** The Downingtown Manufacturing Co. Brit. 395,532, July 20, 1933.

**Felt for paper-making machines.** Firma Christian Petzoldt. Ger. 584,224, Sept. 16, 1933. Felt is made resistant to heat, acids and rot by coating it with a silicate of Mg at any stage of its manuf. Thus, the fiber or yarn or the finished felt may be treated with a soln. of Na silicate and then with a soln. of  $MgCl_2$ .

**Apparatus for regulating the density and flow of paper stuff.** Franz Hassmann. Ger. 583,041, Aug. 28, 1933.

**Apparatus for sifting paper stuff.** "Mieg" Mühlenbau und Industrie A.-G. (Robert Stehr, inventor). Ger. 583,040, Sept. 1, 1933.

**Rosin size.** Judson A. DeCew (to Process Engineers, Inc.). U. S. 1,929,577, Oct. 10. Melted rosin is emulsified with a dil. aq. alk. soln. such as NaOH under conditions unfavorable for the saponification of the rosin, and the emulsion formed is separately treated in a container without diln. and at a temp. below the h. p. under conditions favorable for saponification of rosin, to produce a lighter colored product than would be obtained by boiling the emulsion. App. is described.

**Sizing paper.** I. G. Farhenind. A.-G. Brit. 395,155, July 13, 1933. See Fr. 738,991 (C. A. 27, 2035).

**Machine for drying sheets of paper, etc.** Alfred E. Browne and Charles W. H. Honor. Brit. 394,565, June 29, 1933.

**Waterproofing paper.** Soc. anon. Papeteries Navarre. Brit. 395,197, July 13, 1933. Paper is waterproofed by passing a band thereof upwardly through a bath of viscose and then successively through baths for coagulating and pptg. the viscose, the band being finally washed and dried. App. is described. Before coagulation a no. of bands, 1 or some of which may be of fabric, may be impregnated with viscose and superposed or compd. sheets comprising impregnated and unimpregnated bands may be prepd.

**Watermarked paper.** Magyar Nemzeti Bank and Friedrich von Heinrich. Brit. 395,284, July 13, 1933. Addn. to 373,905 (C. A. 27, 3609). See U. S. 1,901,049 (C. A. 27, 3078).

**Carbon papers.** Unichem Chemikalien-Handelsgesellschaft A.-G. Brit. 395,225, July 13, 1933. See Fr. 744,832 (C. A. 27, 4360).

**Wallpaper.** E. I. du Pont de Nemours & Co. Brit. 394,974, June 30, 1933. Washable and greaseproof wallpaper is made by coating paper with a compn. comprising a cellulose deriv., a sufficient proportion of a wax (-like substance) or a metal stearate, *e. g.*, Zn or Al stearate, to give a matt surface and solvents of the kind used in the prepn. of cellulose lacquers. The cellulose derivs. may be esters, *e. g.*, cellulose nitrate or acetate, or ethers, *e. g.*, Et or benzyl cellulose. Plasticizers, *e. g.*, di-Bu phthalate, tricresyl phosphate, castor oil and  $\beta$ -ethoxyethyl stearate, and modified natural resins or synthetic resins may be added to the coating compns.

**Apparatus for making laminated paper or cardboard.** Alois Purkert, Jr. Ger. 583,162, Aug. 29, 1933.

## 24—EXPLOSIVES AND EXPLOSIONS

CHARLES B. MUNROE AND C. O. STORM

**Testing safety explosives with respect to detonating gases.** Jean Sedivy. *Chimie & industrie Special No.*, 976-7 (June, 1933).—Tests by Dautriche's method showed that, for a given total charge, the size of the flame and the speed of detonation decrease as the no. of cartridges into which the charge is divided is increased. A. P.-C.

**Liquid oxygen explosives.** T. Coulter and A. E. Lance. *J. Chem. Met. Mining Soc. S. Africa* 34, 57-73 (1933); cf. *C. A.* 27, 3079.—Authors' reply to discussion. Further tests on sensitiveness to impact, inflammability, formation of  $\text{CO}_2$ , ignition of fire damp, extent of enrichment of atm., effect of such enrichment in creating an atm. susceptible to coal dust explosion, possibility of coal dust in suspension transmitting a flame and so causing a premature explosion, effect of  $\text{O}_2$  on fuse, etc., are presented. Alden H. Emery

**Manufacture and testing of "methanites."** V. Pelant (*Chimie & industrie Special No.*, 888-901 (June, 1933)).—A detailed description is given of the procedure used for testing "methanites" (safety explosives used in coal mines) in an exptl. tunnel according to Czechoslovakian specifications, and of expts. carried out in Czechoslovakia during the last few yrs. with a view to increasing the safety of such explosives. From a discussion of the procedure now in use, suggestions are made for its modification and improvement. A. Papineau-Couture

**Explosive properties of dioxan-air mixtures.** G. W. Jones, H. Seaman and R. E. Kennedy. *Ind. Eng. Chem.* 25, 1283-6 (1933).—At 100-110° the lower and upper inflammable limits for dry dioxan vapor in air are 1.97% and 22.25% by vol. Ignition temps. were detd. for several vapors by the "quartz-bulb" method and the "drop" method. In the latter a drop of the liquid is placed on the surface of some molten material such as glass. If in the quartz-bulb method the vapor of a given substance gives a concn-ignition-temp. curve whose slope is (a) pos., the drop method gives higher values of ignition temps.; (b) neg., it gives ignition temps. equal to or lower than does the quartz-bulb method. Thus the combustion properties depend upon conditions of test. R. E. Anderson

**Photographic studies of detonation of explosives.** Ladusz Urbański. *Roczniki Chem.* 12, 715-60 (768-9 in French) (1932), cf. *C. A.* 27, 4930. The detonation process of picric acid and nitrocellulose was studied by means of a high-speed camera permitting the dissection of a detonation flame into a series of pictures differing from each other by a distance of  $\frac{1}{10,000}$  of a sec. With picric acid the primary flame represents the main and partly the secondary reaction and consists of a center surrounded by luminous bundles. The progress of the secondary reaction depends on the rate of cooling of the reaction products effected by reduction of the pressure. The luminescence is due to glowing of free C and is induced by various reactions in the explosion space. The photographic record permits the establishment of the following scheme of the explosion progress: The charge, being the center of the primary flame, is the place of the decomposition of the explosive. The decomposition products interact immediately, forming brighter reaction zones upon a darker field. This state is especially well perceived in photographing blue rays, in case the explosive is confined only with celluloid or is entirely free. If it is placed in a glass tube, the different zones run into each other causing brightening of the whole field, upon which darker bands are visible. The interacting decomposition products diverge and form luminous bands around the center. The glowing ceases with time toward the inner part whereby rings around the center are formed. The diam. of the rings decreases steadily until the light is extinguished. The space between the center and the rings is illuminated by numerous radiant points. Analysis of the primary flame permits the conclusion that the reactions of the primary decomposition products do not proceed evenly in the whole

mass, but are broken up into secondary centers forming rings around the place of the detonation. The flame along the charge axis shows all characteristics of an explosion flame. After extinction of the primary flame, a secondary one appears induced by oxidation of the reaction products: C, CO,  $\text{CH}_4$ ,  $\text{H}_2$ , HCN, etc. The primary flame contains all colors of the visible spectrum; in the secondary one, blue is observed feebly, red and infra-red intensely. The lowest temp. limit of the primary flame is calcd. to 2000-2200°. Nitrocellulose behaves similarly, except that the form of the rings around the center is more regular, and their diam. is smaller than with picric acid. The lowest temp. of nitrocellulose, having 13.3% N, is calcd. to 1900-2000°. J. W.

**Electrochemical testing of the stability of explosives.** A. Pavlik. *Chimie & industrie Special No.*, 978-1005 (June, 1933).—Description of an investigation into Hansen's potentiometric method (*Dansk Artillerie Tidsskr.* 12, 129 (1925)), consisting of detg. the  $p_{\text{H}}$  of the ext. of explosives subjected to stability tests, with a discussion of the applicability of the test and a comparison with other stability tests. It was found suitable for testing nitroglycerin, nitroglycerin smokeless powders, nitrocellulose and penthrate, but not for trinitrotoluene, picric acid nor trimethylenenitrosoamine; it may or may not be suitable for dynamite according to the compn. of the latter. The great advantage of the method lies in the fact that it permits of drawing a decomposition curve which gives a more complete picture of the effects of a heat test than a test like the Abel, which merely indicates the degree of decomposition at a given moment. The potentiometric measurements were carried out with the quinhydrone electrode, which is suitable only for a  $p_{\text{H}}$  range of 2.5-6 (with explosives). A few polarograms were detd. by means of the Hg-drop electrode, and further investigation will be carried out along this line. A. Papineau-Couture

**Internal ballistics considered as a link between the manufacture and consumption of smokeless powder.** V. Benda. *Chimie & industrie Special No.*, 1006-10 (June, 1933).—Math. A. Papineau-Couture

**Determination of stabilizers in smokeless powders.** F. Becker and G. A. Hunold. *Z. ges. Schiess-Sprengstoffw.* 28, 233-7, 284-6 (1933).—Volumetric and gravimetric methods are described in detail for the detn. of diphenylamine, diethyldiphenylurea (centralite), diphenylurea (Akardit), alone or in presence of each other in smokeless powders of both single-base and double-base types. In general the methods are accurate to within 10% of the amt. of stabilizer present (usually between 0.5 and 5%). This accuracy is considered satisfactory for the purpose. C. G. Storm

**The importance of the composition of nitroglycerin spent acid to a rational manufacture of nitroglycerin.** Gosta Wallerius. *Z. ges. Schiess-Sprengstoffw.* 28, 169-72, 203-6, 247-50, 280-4 (1933).—W. discusses the effect of variations in  $\text{HNO}_3$  and  $\text{H}_2\text{O}$  contents of spent acids on soly. of nitroglycerin. Spent acid of compn. having min. solvent action does not lead to max. yield, since yield is a function of both soly. and quantity of spent acid. The soly. of nitroglycerin was detd. in 24 acid mixts. and curves were plotted showing relations between dissolved nitroglycerin and (a)  $\text{HNO}_3$  content, and (b)  $\text{H}_2\text{O}$  content. A method is described for calcg. the proportion and compn. of nitrating acid to give max. yield, with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  of given concns. Tables show results of a large no. of such calcns. C. G. Storm

**The heats of formation of nitrocelluloses, nitroglycerin and other important constituents of propellants.** A. Schmidt and F. Becker. *Z. ges. Schiess-Sprengstoffw.* 28, 280-2 (1933).—Six samples of nitrocellulose covering a range of N content from 11.05 to 14.12% were prepd. and their heats of combustion detd. in the micro-combustion bomb. N was detd. by the Lunge method and at. compn. calcd. A linear relation exists between the heats

of formation calcd. from these data and the N content (cf. C. A. 26, 2641). Results ranged from 754 Cal./kg. with 11.05% N to 800 Cal./kg. with 11.12% N. Heats of combustion were also detd. and heats of formation calcd. for nitroglycerin, substituted ureas and urethans and dinitrotoluene. Results are tabulated. C. G. S.

The determination of diphenylamine by bromination, with special regard to its application in the analysis of smokeless powders. L. Galatis and J. Megaloikonomos. *Z. ges. Schiess-Sprengstoffw.* 28, 273-7 (1933). A series of detus. carried out on pure  $\text{Ph}_2\text{NH}$  and on various types of both nitrocellulose and nitroglycerin smokeless powders contg. centralites, or dinitrotoluene, in addn. to  $\text{Ph}_2\text{NH}$ , showed that the inaccuracy of the usual bromination method for detn. of  $\text{Ph}_2\text{NH}$  could be largely overcome. The tetrabromide ppt. is filtered from the alc. liquid and weighed, a correction being applied for soly in the  $\text{EtOH}$ .  $\text{MeOH}$  may be used with equal results and is preferable in presence of dinitrotoluene. A pure colorless tetrabromide is obtained if the Br is diluted 5-fold with alc., and if this soln. is added until the liquid has the color of 0.1 N  $\text{K}_2\text{Cr}_2\text{O}_7$  soln. C. G. Storm

The combustion of two colloidal powders of different compositions but with the same explosive temperature. Henri Murrou and G. Aunis. *Bull. soc. chim.* 53, 613-17 (1933); cf. C. A. 27, 2302. The powders are made up of varying amts. of nitroglycerin, nitrocellulose and diethyldiphenylurea. If the temps. of the explosions are equal the combustion velocities are the same in spite of the difference in compn. and in spite of the varying amts. of nitric N in the products of combustion. H. A. Smith

The ignition of gases. VIII. Ignition by a heated surface. (a) Mixtures of ethane, propane or butane with air. (b) Mixtures of ethylene, propylene or butylene with air. C. A. Naylor and R. V. Wheeler. *J. Chem. Soc.* 1933, 1240-7; cf. C. A. 26, 1124, 4951. (a) Lowest ignition temps. and longest ignition lag for  $\text{CH}_4$ -air mixts. occur with excess of  $\text{O}_2$ , whereas for higher paraffins the opposite is true. Traces of  $\text{I}_2$ ,  $\text{C}_2\text{H}_4$  or  $\text{C}_2\text{H}_5\text{Br}$  retard sub ignition-temp. reactions of  $\text{CH}_4$ -air, but accelerate those of  $\text{C}_2\text{H}_6$ -air. Ignition temps. depend on the size of the reaction vessel, being lower for a large vessel. (b) Ignition temps. decrease with increasing mol. wt. of hydrocarbon. Rates of reaction are influenced more by concn. of hydrocarbon than by that of  $\text{O}_2$  in the mixt. Oxidation to aldehyde is the most important reaction leading to the production of flame. Of these olefins, propylene shows the lowest rate of reaction, possibly because of steric hindrance. R. F. Anderson

A new principle for detonators and its practical application. A. Majrich. *Chimie & industrie Special No.*, 926-32 (June, 1933).—Certain substances, such as basic Pb picrate, Pb trinitroresorcinol, Pb nitrate-hypophosphite, Hg acetylide and Na fulminate, burn at a fairly rapid rate, but without exploding; yet, by a phenomenon which might be called "explosio-ismicrism," they can induce explosion of explosives. This property is based on a principle entirely different from the action of ordinary detonator explosives, namely, adiabatic compression of the explosive charge produced by the rapid combustion of the primary "explosive." Contrary to the principle of the usual detonator, acceleration takes place in the main charge, but not in the detonator. The max. pressures produced by adiabatic compression and the rates of combustion are calcd., and the practical application of the principle to the manuf. of detonators is indicated. A suggested explanation, based on this new principle, is given of the Munster Univ. explosion and of the Oppau disaster. A. Papineau-Couture

Controlling the quality of safety fuses by the galvanoscope. Karl Pečák. *Chimie & industrie Special No.*, 933-8 (June, 1933).—An elec. current, not more than 300 v., is passed through the fuse, and measured by means of the resultant galvanometer deflection. The method can be applied to the finished fuses and detects defects which are not revealed by other methods. A. Papineau-Couture

Improved fire damp detectors. O. Muller and H. Wöhlbier. *Z. ges. Schiess-Sprengstoffw.* 28, 277-80, 317

19 (1933).—A review with description of types.

C. G. Storm  
Explosion tests of Pittsburgh coal dust in the Experimental Mine, 1925 to 1932, inclusive. Geo. S. Rice, H. P. Greenwald and H. C. Howarth. *Bur. Minas. Bull.* 369, 44 pp. (1933).—The increased effectiveness of rock dust caused by increasing the amt. of the —200-mesh dust 50-100% over the 20%—200-mesh usually specified is too small to justify crushing costs. Various methods of ignition are described and their relative igniting and dust-raising powers discussed. The effect of the varying quantity of dust present is considered. Tests showed that small accumulations of gas that might pass unnoticed can be exceedingly dangerous; 150 cu. ft. of a gas-air mixt. contg. 9-10% natural gas initiated dust explosions. Tests on stratified gas and on the ignition of coal dust by elec. arcs are described. Alden H. Emery

The waterless gas holder accident at Neunkirchen. Report of the Gasholder Subcommittee. Institution of Gas Engineers. *Gas World* 99, 428-9; *Gas J.* 204, No. 3876 Institution of Gas Engineers Suppl., 5-6 (1933).—The M. A. N. waterless gasholder (capacity 4,250,000 cu. ft.) at Neunkirchen exploded on Feb. 10, 1933, during the course of repairs on the mains. Conclusion (as the result of an inspection of the site a month later): If the precautions normally taken in England during the repairs to mains had been observed, the disaster would not have occurred. P. J. Wilson, Jr.

Inflammation of coal dusts (Mason, Wheeler) 21.  
Limits of inflammability of natural gases (Jones, Kennedy) 21.

Priming mixture for explosives. Joseph D. McNutt (to Winchester Repeating Arms Co.). U. S. 1,930,653, Oct. 17. Pb dinitrophenylazide is used with a heavy metal salt of tetrazene such as the Ag salt (suitably also with  $\text{PbO}$ ,  $\text{Ba}(\text{NO}_3)_2$ , gum and  $\text{SbS}$ ). Cf. C. A. 27, 3612.  
Charges for detonating caps. Josef Meissner. U. S. 1,930,765, Oct. 17. A primary charge consisting of a mixt. of about 0.15 g. TNT and 0.03-0.1 g. Pb azide is used with a secondary charge of TNT about 0.4 g. and Pb azide about 0.1 g.

Detonators for explosives. Sylvester B. Large (to Atlas Powder Co.) U. S. 1,928,204, Sept. 26. In compnd detonators, the primary detonating substance used is a solid explosive of the general formula  $\text{C}_n\text{H}_{n+2}(\text{NO}_2)_n$  such as hexanitromannite which may be used with a base charge of tetryl. U. S. 1,928,205 relates to detonators with a primary initiating charge of a solid nitration product of a polyhydric alc. having the general formula  $\text{C}_n\text{H}_{n+2}(\text{OH})_n$  such as hexanitromannite and provided with a preformed fuse head such as one comprising  $\text{KClO}_3$  and Hg fulminate of a nature adapted to deliver a hot semi-explosive burst of flame upon the primary initiating charge. U. S. 1,928,206 relates to detonators having a primary detonator compn. free of all explosives as sensitive to friction as Hg fulminate and Pb azide and including a mixt. of a solid nitration product such as a nitromannite and at least one other solid explosive ingredient, such as nitroacetone, which is less sensitive to friction and impact than Hg fulminate and Pb azide. U. S. 1,928,207 relates to detonators with a primary detonator compn. consisting of a solid disaccharide nitric ester such as nitroactose, etc. U. S. 1,928,208 relates to a detonator comprising a shell, a primary "safety" charge in the shell, a confining element for the charge in the shell, and an igniting medium for the charge, the character and amt. of the igniting medium being such, with respect to the strength of the shell and 9 confining element, that these are completely resistant as to impairment of the confinement of the primary charge under the heat and pressure developed within the shell up to the time of detonation of the primary charge. Numerous details and examples are given.

Blasting detonators. Mario F. F. Biazzi. *Brit.* 387,545, Feb. 9, 1933. In mfg. a blasting detonator comprising a secondary charge in a case surmounted by a primary charge in a capsule, the primary and secondary charges are

previously compressed in their resp. containers and the capsule is then pressed down on the secondary charge so that the zones of highest compression are in juxtaposition. The primary charge may be Hg fulminate in a Cu capsule in an Al case contg. a nitroaromatic compd.; or the case may be of Cu and the capsule of Al filled with Pb azide. Part of the secondary charge may be inserted in the capsule or an intermediate charge of nitropentaerythrite, trimethylenetrinitroamine or the like may be used.

1 Apparatus for mixing blasting explosives. R. I. du Pont de Nemours & Co. Brit. 395,759, July 24, 1933. The app. comprises an annular metal bowl, non-metallic, revolving wheels adapted to pass through the ingredients and means for regulating the temp. of the bowl. Adjustable scrapers for the edges of the bowl and a rake are provided. The bowl is made of a non-parking alloy consisting of Cu 94.8%, Si 3.4% and Mn 1.5%. The scrapers and rake are preferably of hard rubber.

## 25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Notes on the determination of the constitution of azo dyestuffs. Vladimir Kfepelka. *Chimie industrie Special No.*, 903 5 (June, 1933). The methods described in modern literature for the identification of the products obtained by reduction of azo dyestuffs are complicated and are not universally applicable. They can be simplified and modified in such a manner that Green's original observation regarding the color produced by oxidation in ammoniacal soln. can be made the basis of a single scheme of identification for all such dyes. All constituents of azo dyes which have been enriched by 1 or 2  $\text{NH}_2$  groups by reduction, when applied to filter paper in a soln. of given  $\text{NH}_3$  concn., give a characteristic color by the action of atm.  $\text{O}_2$ ; this color is changed by the action of  $\text{HCl}$ , as indicated by Green, and in an even more pronounced manner by  $\text{NaOH}$  soln., which permits of their almost instantaneous and infallible identification. Similarly, nonsulfonated  $\text{C}_6\text{H}_5$  derivs., such as  $\text{C}_6\text{H}_5(\text{NH}_2)_2$ ,  $\text{C}_6\text{H}_5(\text{NH}_2)_3$ , aminohydroxy derivs., such as aminoresorcinol, diaminesorcinol, etc., give characteristic colors.

A. Papineau-Couture

Investigations of the vat dyes of the benzanthrone series. V. The preparation of Bz 1 chlorobenzanthrone. 2. Toshio Maki and Yoshio Nakai. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 520 31 (1933), cf. *C. A.* 27, 3431. When 0.3 g. or 10% cc. (at 20°)  $\text{Cl}_2$  was introduced into a homogeneous soln. of 12.5 g. benzanthrone in 150 cc. glacial  $\text{AcOH}$ , at 100°, the optimum time of reaction for the formation of Bz-1-chlorobenzanthrone was 17 min. The yield of pure  $\text{Cl}$  deriv. (13.36–13.30%  $\text{Cl}$ ), pptd. twice from glacial  $\text{AcOH}$ , was 80.2% of the benzanthrone or 69.4% of the theoretical yield. The benzanthrone concn. of the glacial  $\text{AcOH}$  soln. is not a straight-line function of the corresponding optimum time of chlorination.

Karl Kammermeyer

Standards for determining the fastness of dyes toward washing, perspiration and water. Report of the Polish sub-committee on the fastness of dyes. Wladimir Mazanski. *Ann. chim. anal. chim. appl.* 15, 433–41 (1933). The principles involved, the necessary app. and procedure to be followed are described. W. T. H.

A method of determining the fastness of dyestuffs with 'lousaints' photocolormeter. Jules Pinte. *Bull. fedération intern. assoc. chim. textile couleur* 2, 90 (1933).—Spectrophotometric readings at 410, 460, 530, 575, 620 and 680 m $\mu$  are taken for a dyestuff (in powder form or in soln.) with Wratten filters. The change in the reflectivity of the fabric or powder on exposure to light under standard conditions is called and used as an index of the fastness of the dyestuff. S. Lenher

Influence of light on vat dyeings. A. Landolt. *Bull. federation intern. assoc. chim. textile couleur* 2, 102 (1933).—Cotton dyed or printed with certain vat colors is tendered by exposure to light. The tendering after a normal long exposure has been correlated with that caused by a short exposure of the same sample impregnated with a dil. soln. of  $\text{NaOH}$ . The tendering colors cause fading of other colors when applied in mixts. The acylaminoanthraquinones and the dianthraquinonyl amines cause severe tendering, while the anthraquinonazines and the derivs. of benzanthrone are inoffensive. With the thiondigoids the derivs. of thionaphthene are to be feared in spite of the antioxidant  $\text{NH}_2$  group in the mol. Blues and greens are

least objectionable of the various shades. A list of safe vat colors is given. S. Lenher

3  $rH$  in dyeing. Maurice Deribere. *Tiba* 11, 729 37 (1933).—An explanation of the notion of  $rH$  (decimal colog. of the equil. H pressure over the soln.), of its electrometric and colorimetric detn., and of its applications to chem. phenomena, more particularly in dyeing.

A. Papineau-Couture

Theory of the dyeing process. A. E. Porai-Koshitz, A. Efimov, I. Shapiro, I. Riskin, N. Gorelik, M. Peskin, E. Veller, N. Sokolova and E. Vasil'eva. *J. prakt. Chem.* 137, 179 215 (1933). The mechanism of dyeing with substantive acid (cotton) dyes is investigated by using a neutral dye bath of the  $\text{NH}_4$  salt of the dye and detg. the  $\text{NH}_4$  set free. Wool has a weak affinity for  $\text{NH}_4$  which is removed by boiling in  $\text{H}_2\text{O}$ . When wool is dyed in such a dye bath at the h. p.  $\text{NH}_4$  is evolved proportionally to the dye absorbed (allowance being made for the affinity of the wool for  $\text{NH}_4$ ). With cotton, however, the dye is absorbed as a whole and no  $\text{NH}_4$  is evolved. No appreciable dyeing occurs when wool is boiled in a neutral soln. of the Na salt of the dye, but in presence of  $\text{NH}_4$  salts dyeing takes place with evolution of  $\text{NH}_4$ . The effect is not one of "salting out" as in the case of cotton, for whereas  $\text{Na}_2\text{SO}_4$  and  $\text{NH}_4\text{Cl}$  have an equal effect in dyeing cotton, only the latter is really effective in the case of wool. As  $\text{NH}_4$  salts do not ppt. the dye acids, this new technique makes it possible to use substantive dyes on wool that previously were considered unsuitable. The satn. value of wool for acid dyes is a stoichiometric relationship independent of the nature of the dye (cf. Meyer, *C. A.* 20, 3350), and is equal to the value for mineral acids ( $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ). Wool satd. with  $\text{H}_2\text{SO}_4$  from a 0.25  $\text{N}$  soln. takes up dye (Chicago Blue 6B) equiv. to the  $\text{H}_2\text{SO}_4$  present. Mutual replacement of dyes can occur when dyed wool is immersed in a soln. of a different dye ( $\text{NH}_4$  salt); if the wool is satd., no  $\text{NH}_4$  is evolved. Conclusion: Whereas cotton dyeing is a purely phys. process of adsorption, the dyeing of wool is a chem. process arising from combination of the dye acid with the basic wool fiber. An explanation is offered of the anofhalous behavior of Alkali Blue, which is taken up by wool from weakly alk. baths, but then gives dull, weak shades which develop into blue on addn. of acids. It is shown that the behavior of wool free from volatile bases with the  $\text{NH}_4$  salt of the dye is normal and that the anion alone enters the fiber. It is suggested that in presence of alkali it does so in the carbinol form, which is dehydrated to the colored quinonoid form by acids. B. C. A.

Colloid-chemical processes in the dyeing of cotton. Albert Schaeffer. *Angew. Chem.* 46, 618 22 (1933). Dispersion tests were carried out on dyes of all classes by the method of Auerbach, as well as by dialysis and ultrafiltration through standardized ultrafilters. The results are presented in schematic form. Present-day information leads to the belief that cotton dyeing consists of 3 phases: (1) diffusion of the dye into the sub-microscopic voids of the fiber, (2) adsorption of the dye and (3) irreversible fixation of the dye. Further theoretical possibilities are discussed. Seventeen references.

The effect of the products of hydrolysis of wool on dyes of the thiocyanine GR group. N. Nikolaev. *Anilino-krasochaya Prom.* 1931, No. 2-3, 28-34; *Chem. Zentr.* 1932 I, 1298.—Expts. were carried out to det. the cause of brown specks on textiles dyed with "Sulfocyanin GR" and "Sulfocyaninschwarz 2B." Addn. of NaCl or Na<sub>2</sub>SO<sub>4</sub> to a soln. of either dye in distd. H<sub>2</sub>O does not change the shade. Addn. of alk. earth carbonates ppts. some of the dye, which redissolves upon the addn. of AcOH. In dyeing wool with thiocyanine GR in distd. H<sub>2</sub>O a deep blue shade is obtained at both 80° and 100°. In tap water the color is somewhat duller at 80°, and at 100° a red-brown shade is obtained. The addn. of alkali carbonates to the bath decomposes the dye on wool fibers very quickly; alk. earth carbonates decompose it more slowly. That the effect is due to products of the hydrolysis of wool is shown by the fact that a soln. of soda in which wool has been boiled and removed changes the dye to orange. Analogous expts. using CaCO<sub>3</sub> and MgCO<sub>3</sub> instead of soda showed no effect on the dye. The products of hydrolysis therefore form insol. compds. with Ca and Mg which remain on the fibers. Expts. with wool extd. with ether did not substantiate the claim that fat and soap residues remaining on the wool have a reducing and decomp. action on the dye. However, S compds. formed during hydrolysis do have this action on thiocyanine dye. The gases evolved during boiling wool turn an aq. soln. of the dye orange. Both sulfate and sulfite can be detected in an alk. soln. in which wool has been boiled. The content of the latter is entirely sufficient for the decomp. of the dye on the fibers. M. G. Moore

Ultramarine blue imitation and laundering blue. C. Becher. *Seifensieder-Ztg.* 60, 743-4, 764-6, 781, 799-800 (1933).—B. considers the manuf. of various substitutes for ultramarine blue and washing blue. P. Escher

Colors for colored-paper manufacture. Alois Triltsch. *Farben-Chem.* 4, 365-9 (1933). The suitability of various types of dyes, pigments and methods for coloring and dyeing paper is discussed. Formulas are given for the prepn. of bronze, fiery red, violet, green and yellow pulp colors. G. G. Sward

White and colored discharges on naphthylamine garnet by means of hyposulfite formaldehyde. Lucien Baumann, G. Thesmar and A. Hug. *Bull. soc. ind. Mulhouse* 99, 467-71 (1933). (Scaled note of 1905.) Report. M. Battegay and J. Lichtenberger. *Ibid.* 475.—The process consists of a combination of discharge by "rongalite" (formaldehydesulfoxylate) in the presence of an Fe salt and of nitrite, with discharge in the presence of an aromatic base and an org. acid. I. H. Odell

X-ray investigation of natural and regenerated silks. Ichiro Sakurada, Keiroke Futino. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 21, 266-9 (1933).—Identi-

cal x-ray photographs are obtained from *Antheraea pernyi* and *Antheraea yamamai* while the photograph from *Bombyx mori* is different. One prepn. of tegusu gave a photograph identical with that from *Bombyx mori* while 2 other preps. of tegusu gave photographs similar to those of the pernyi and the yamamai. Dispersion and regeneration changes the lattice structure of the silk fibrils very slightly.

Howard Agnew Smith

Viscosity investigation of silk solution. I. Effect of nickel and copper in the ammoniacal solution. Hiroshi Sobue and Saburo Manago. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 576-9 (1933).—The swelling of various boiled-off silks in cuproammonia soln. was observed under the microscope and it was found that with raw silk the degree and velocity of swelling are great, while for mildly boiled-off silk the degree of swelling is fairly great but the velocity is small, and for severely boiled-off silk the velocity of swelling is great. The viscosities of cuproammonia and Ni oxide ammonia solns. and of their mixts. are presented. The exptl. results show that the swelling of silk particles is a min. in a mixt. of CuO-ammonia soln. and a small amt. of NiO-ammonia soln. at a temp. of 30°.

Karl Kammermeyer

The action of alkaline copper solution on silk fibroin. II The solution phenomena in the system fibroin-copper amine 1. Yujiro Takamatsu. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 566-7 (1933); cf. *C. A.* 26, 2323.—In Schweizer's soln. the fibroin is dissolved so rapidly that in 1/2 hr. 90% of the fibroin is dissolved and in 4 hrs. the soln. may be complete. The effects of oxidation due to air during the treatment are almost negligible.

The soly. of fibroin in Cu-amine soln. is increased with increased amts. of fibroin used and the fibroin is brought completely into soln. without leaving any solid phase till it reaches its max. soly. But if the amt. of fibroin is increased still more the soly. of fibroin is decreased. These abnormal phenomena are comparable with those usually observed in the soln. of colloidal substances, when their solubilities are greatly affected by the amts. of substance used. The max. degrees of soly. of fibroin in Cu-amine solns. of varying Cu contents were detd. under definite soln. conditions and the following equation was derived: max. degree of soly. of fibroin (Cu content in the soln. = 1, where the chem. equiv. of fibroin was 227 as previously detd. From the solns. of fibroin in Cu oxide-ethylenediamine with fibroin and Cu in a monomol. ratio a complex fibroin-Cu-amine compd. was isolated which contained the 3 constituents in equal proportions. It was ascertained that the smallest amts. of Cu and amine necessary to dissolve a definite amt. of fibroin can be also expressed by this ratio III. The solution phenomena in the system fibroin copper amine. 2. *Ibid.* 567-8.—In the soln. fibroin, Cu and ethylenediamine combine in monomol. ratios, while in the solid phase they exist in the ratios: undissolved fibroin Cu. ethylenediamine = 2:1:1.

Herzog, E.: Reaktionstabelle der Küpfenfarbstoffe und Indigokole. Basel: B. Nepf & Cie. M. 2, bound, M. 2.80.

Dyes. Deutsche Hydrierwerke A.-G. Brit. 393,906, June 12, 1933. Dyes having soap-like properties are made by treating  $\text{OH}$ - or  $\text{NH}_2$ -contg. dyes, as such or at any stage in their manuf., with such org. monobasic sulfonic acids or their halides or such monobasic carboxylic acids, their halides or anhydrides as contain substituted or unsubstituted hydrocarbon radicals of the aliphatic or cycloaliphatic series corresponding to soap-forming carboxylic acids in order to esterify or acylate said  $\text{OH}$  or  $\text{NH}_2$  group. Textiles may be simultaneously dyed and rendered  $\text{H}_2\text{O}$ -resistant therewith. Dyes of the azo, triphenylmethane, azine, oxazine, thiazine, xanthene, acridine and anthraquinone series are specified. The products may be sulfonated. Among examples (1)  $\text{H}$  acid is *N*-acylated with stearyl chloride and the product coupled in alk. soln. with any suitable diazo component and (2) aminoazobenzene, benzeneazo- $\alpha$ - or  $\beta$ -naphthylamine or the aminoazonaphthalenes are condensed with cupric, lauric, oleic or ricinoleic acids or with naphthenic or resin acids and the condensation products sulfonated.

Dyes. Deutsche Hydrierwerke A.-G. Brit. 394,343, June 12, 1933. Divided on 393,906 (preceding abstr.). Dyes having soap-like properties are made by combining with dyes, as such or at any stage in their manuf., high mol. (substituted) hydrocarbon radicals of the aliphatic or naphthenyl series, contg. not less than 10 C atoms, corresponding to soap-forming carboxylic acids, 1 of the components having a labile halogen atom and the other an  $\text{OH}$  or  $\text{NH}_2$  group, the combination being effected by means of the  $\text{OH}$  or  $\text{NH}_2$  group in known manner *per se*.

The radicals of the naphthenyl series are introduced by means of compds. of the general formula, alicyclic ring- $(\text{CH}_2)_x\text{R}$ , where R is  $\text{OH}$ ,  $\text{NH}_2$  or  $\text{Cl}$  and  $x$  is such that the total no. of C atoms is not less than 10. The dyes produce a lather in soln. and gelatinize to soap-like jellies, being therefore useful for printing pastes. Textiles may be simultaneously dyed and rendered  $\text{H}_2\text{O}$ -resistant by them and softness of the fibers attained at the same time. In examples (1) *p*-hydroxyazobenzene is etherified with alkali and octadecyl chloride and the product sulfonated, (2) 2,4-dinitrochlorobenzene is condensed with lauric alcoholate and the product reduced to 1-lauroxy-2,4-diaminobenzene which may be used for the synthesis of azo and acridine dyes and (3) aminoazobenzene, benzeneazo- $\alpha$ - or  $\beta$ -naphthylamine or aminoazonaphthalenes are heated with cetyl chloride and the products sulfonated. Dyes of the triphenylmethane, azine, oxazine, xanthene, acridine or anthraquinone series contg. amino or hydroxy groups, e. g., rosaniline, safranin T or Lauth's violet, may be similarly treated or compds. contg. a labile halogen atom, e. g., fluorescein chloride can be condensed with higher alkylamines and then sulfonated.

Azo dyes. Fritz Muller. U. S. 1,929,328, Oct. 3. Water-insol. azo dyes which, in general, dye yellowish orange shades of good fastness are formed from components such as 1-amino-2,5-bis(trifluoromethyl)benzene and 1-(2',3'-hydroxynaphthylamino)-2-ethoxybenzene, etc.

Azo dyes. Hans Reindel and Hans Krzikalla (to General Aniline Works). U. S. 1,929,853, Oct. 10. Azo dyes which dye wool fast yellow shades are formed from components such as *p*-amino-lauric (or -stearic) acid anilide and 1-(*m*-sulfophenyl)-3-methyl-5-pyrazolone or acetoacetic- $\alpha$ -anilide-sulfonic acid.

Azo dyes. I. G. Farbenind. A.-G. Brit. 394,984, July 4, 1933. The diazo compd. of 2-aminobenzoic acid or a deriv. thereof (1 or 2 mols.) is coupled with a di-(acetoacetyl) deriv. of benzidine or a 3,3'-deriv. thereof (1 mol.), the diazo compd. being selected so that the dye always contains at least 1  $\text{HSO}_3$  group. They dye vegetable fiber yellow shades which on aftertreatment with a Cu compd. become very fast to light and washing. In examples (1) 1-sulfo-2-aminobenzoic acid (I)  $\rightleftharpoons$  di-(acetoacetyl)-*o*-toluidine (II) (greenish yellow on aftertreatment with  $\text{CuSO}_4$ ), (2) I  $\rightarrow$  II  $\leftarrow$  2-aminobenzoic acid and (3) 5-sulfo-2-aminobenzoic acid  $\rightarrow$  II.

Azo dyes. I. G. Farbenind A.-G. (Rudolf Knoche and Detlef Delfs, inventors). Ger. 576,546, May 11, 1933. Dyes are produced by treating azo dyes contg. the grouping  $\text{o-C}_6\text{H}_4\text{N NR}_2(\text{OH})\text{o}$ ,  $\text{R}_1$  and  $\text{R}_2$  being aromatic residues, with  $\text{Cr}$ -yielding agents in an alk. medium till the  $\text{Cl}$  is replaced by  $\text{OH}$  and a complex  $\text{Cr}$  compd. of *o*-hydroxyazo dye results. Thus, the dye from diazotized 1-chloro-2-aminonaphthalene-6-sulfonic acid and 2-hydroxynaphthalene is treated with  $\text{Cr}_2\text{O}_3$  in  $\text{KOH}$  to give a blue dye. Another example is given.

Azo dyes. Soc. pour l'ind. chim. à Bâle. Ger. 583,224, Aug 31, 1933. *o*-Hydroxyazo dyes, obtained by coupling diazotized *o*-aminophenols with resorcinol, are treated with a suspension of a Co compd. in a neutral medium. The treatment of dyes contg. the  $\text{COOH}$  group or a group contg.  $\text{SO}_2$  is excluded. Dyes which contain Co and are useful for coloring lacquers are obtained. Examples are given.

Azo dyes; dyeing. Soc. pour l'ind. chim. à Bâle. Ger. 583,223, Aug. 31, 1933. Diazo or tetrazo compds. are coupled in substance or on the fiber with pyrazolone derivs. of the formula  $\text{PRCONHR}'$ , where P is a pyrazolone residue, R is an aryl residue and  $\text{R}'$  is an aryl residue contg. at least 2 nuclei. Dyes or dyeings of various colors are obtained. Examples are given.

Monoazo dyes; dyeing. Soc. pour l'ind. chim. à Bâle. Brit. 393,873, June 15, 1933. Monoazo dyes suitable for dyeing cellulose esters and ethers, natural or artificial resins, lacquers or varnishes, are made by coupling an aromatic diazo compd. that contains no  $\text{OH}$  group in *o*-position to the diazo group with a 1-amino-3-hydroxybenzene having free 4- and 6-positions so that coupling occurs in 4-position and acylating the dyes thus obtained. Greenish yellow to orange non-phototropic shades are

obtained. The dyes may be made into pastes or dry preps. with suitable dispersing agents. Suitable acylating agents are  $\text{HCOOH}$ ,  $\text{Ac}_2\text{O}$  or  $\text{AcCl}$ , propionic anhydride, Et or Me chloroformate or a cyanate. Among examples (1)  $\text{PhNH}_2$  or *p*-anisidine (I)  $\rightarrow$  (neutral) *m*-aminophenol is treated with  $\text{Ac}_2\text{O}$  and (2) the dye obtained in (1) from I is dissolved in finished nitrocellulose lacquer.

**Disazo dyes.** I. G. Farbenind. A.-G. (Karl Wiedemann and Heinrich Clingstein, inventors). Ger. 576,614, May 16, 1933. Disazo dyes obtained by the alk. coupling of tetrazotized aromatic diamines contg. an alkoxy group in the *o*-position to each amino group, with 2 mols. of 2-amino-5-hydroxynaphthalene-1,7-disulfonic acid or with 2 mols. of an *N*-acyl compd. thereof, or with 1 mol. of 2-amino-5-hydroxynaphthalene-1,7-disulfonic acid (or an *N*-acyl deriv.) and 1 mol. of a hydroxynaphthalenesulfonic acid, are treated with Cu-yielding agents in the substance. In an example, 4,4'-diamino-3,3'-dimethoxybiphenyl is tetrazotized and coupled with 2-acetyl amino-5-hydroxynaphthalene-1,7-disulfonic acid in soda-alk. soln. The isolated dye is treated with  $\text{CuSO}_4$  in lime-free water to give a dye coloring cotton and silk in reddish blue shades. Other examples are given. (C. A. 27, 3830).

**Disazo dyes; dyeing.** Imperial Chemical Industries Ltd. and Arthur H. Knight. Brit. 395,005, June 30, 1933. Disazo dyes are prepd. by coupling a diazotized nitroamino compd. of the  $\text{C}_6\text{H}_4$  or  $\text{C}_6\text{H}_3$  series, including derivs. thereof devoid of OH,  $\text{HSO}_3$ , or  $\text{COOH}$  groups, with a 2,5-dialkoxyaniline similarly devoid of OH,  $\text{HSO}_3$ , and  $\text{COOH}$  groups and capable of rediazotization after coupling, rediazotizing and coupling with amines of the  $\text{C}_6\text{H}_4$  or  $\text{C}_{10}\text{H}_8$  series devoid of OH,  $\text{COOH}$  or  $\text{HSO}_3$  groups in the aryl nucleus and customarily used as end components. The products dye cellulose esters and ethers clear blue to violet shades. They are applied as aq. emulsions. Among examples (1) *p*-nitroaniline  $\rightarrow$  2,5-dimethoxyaniline (I)  $\rightarrow$  *m*-phenylenediamine and (2) *o*-nitroaniline  $\rightarrow$  I  $\rightarrow$  4-chloro-*m*-phenylenediamine. In an example of dyeing the products are applied to cellulose acetate from a bath contg. a naphthalenesulfonic acid  $\text{CH}_3\text{O}$  condensation product. In 395,006, June 30, 1933, disazo dyes are prepd. by coupling a diazotized aniline or naphthylamine, or substitution deriv. thereof other than a  $\text{NO}_2$ , OH,  $\text{HSO}_3$ , or  $\text{COOH}$  deriv., with a 2,5-dialkoxyaniline, rediazotizing and coupling with amines as described in 395,005. The products dye cellulose esters and ethers clear violet-red to blue-violet shades. They are applied as aq. suspensions. Among examples (1) *o*-chloroaniline  $\rightarrow$  I  $\rightarrow$  ethyl-*o*-naphthylamine and (2) 5-chloro-*o*-toluidine  $\rightarrow$  I  $\rightarrow$  *o*-naphthylamine.

**Trisazo dyes.** Chem. Fab. vorm. Sandoz. Ger. 582,309, Aug. 11, 1933. Addn to 566,471 (C. A. 27, 1189). One mol. of a tetrazo compd. is coupled in mineral acid soln. with 1 mol. of 1-amino-8-naphthol 3,6-disulfonic acid, and the product is coupled in alk. soln. with 1 mol. of a diazo compd., which may be sulfonated, and 1 mol. of a *N*-substituted *m*-aminophenol, which may also be sulfonated and which must contain more than one sulfo group when an un-sulfonated diazo compd. is used. Black dyes particularly useful for dyeing leather are obtained. Examples are given.

**Vat dyes.** I. G. Farbenind. A.-G. (Georg Kranzlem, Heinrich Vollmann and Werner Schultheis, inventors). Ger. 584,010, Sept. 13, 1933. Pyrene is heated to 110-180° with an aromatic carboxylic acid chloride, unsubstituted in at least one *o*-position to the  $\text{COCl}$  group, in the presence of  $\text{AlCl}_3$  and a dehydrogenating agent, e. g., air or  $\text{MnO}_2$ . A flux may be added to the mixt., e. g., an alkali halide. The examples describe the prepn. of orange dyes from pyrene and benzoyl, *m*-chlorobenzoyl, *p*-toluyl, and *o*-naphthoyl chlorides.

**Vat dye compositions.** I. G. Farbenind. A.-G. (Sebastian Gassner and Hermann Bergwald, inventors). Ger. 583,315, Sept. 1, 1933. Printing pastes and other compns. contg. unreduced vat dyes are improved by inclusion of alkali salts of hydroaromatic sulfonic or

carboxylic acids. Glycerol or like water-sol. alc. may also be included. Printing pastes contg. reduced vat dyes may be similarly improved. Examples are given.

**Vat dyes of the anthraquinone naphthacridone series.** Philip F. Bangham and Robert F. Thomson (to Imperial Chemical Industries Ltd.). U. S. 1,929,870, Oct. 10. Vat dyes which yield fast gray shades are formed by nitrating anthraquinone-1,2,2',1'-naphthacridone to introducing at least 2 nitro groups, reducing the nitro deriv. formed to an amino deriv. and benzoylating the resulting amino compd. The reduction may be effected by heating the nitro compd. with Na sulfide and the benzoylation by heating the amino compd. with benzoyl chloride in  $\text{PhNO}_2$ .

**Yellow to brown to violet vat dyes.** Georg Kalischer, Heinrich Ritter and Fritz Baumann (to General Aniline Works). U. S. 1,931,196, Oct. 17. Various examples are given of the production of dyes by condensing thiophenanthronecarboxylic acid halides with amino derivs. of cyclic ketone compds. such as  $\alpha$ -mono- and dianthranthraquinones, anthranthraquinones and their carbazolic derivs., anthranthraquinones, aminopyranthrones, aminodibenzanthrone, aminodibenzopyrenequinones, their substitution products and derivs., aminothiazoloanthrone-sulfone and aminocetamidones.

**Anhydrous leuco vat dyes.** Ronald S. Barnes, John E. G. Harris, Burtell Wylam and John Thomas (to Scottish Dyes, Ltd.). U. S. 1,930,109, Oct. 10. For the prepn. in a liquid medium of an anhyd. leuco compd. of an anthraquinone or indigoid vat dye, an aq. prepn. of the leuco compd. is added to  $\text{PhCl}$ ,  $\text{PhNO}_2$  or dimethylaniline, and water is removed by distn. under a suitable pressure.

**Derivatives of vat dyes.** I. G. Farbenind. A.-G. (Walter Meig and Rudolf M. Heidemeich, inventors). Ger. 583,070, Aug. 28, 1933. Leuco compds. of vat dyes are treated with a *m*-sulfonyl halide of benzoic acid in the presence of a tertiary org. base. Water-sol. esters of the leuco compd. are obtained. Examples are given. The products are decomposed by alkalis, and are useful in dyeing and printing.

**Sulfuric esters of leuco compounds of vat dyes.** I. G. Farbenind. A.-G. (Wilhelm Bauer, Ludwig Zeh and Bernhard Bollweg, inventors). Ger. 583,071, Aug. 28, 1933. Addn to 578,323 (C. A. 27, 4410). The method of Ger. 583,331 modified by using salts of dithiocarbamic acid or of polythiocarbamic acid as reducing agents in place of  $\text{CS}_2$  and  $\text{NH}_3$ , or an amine. Examples are given.

**Anthraquinone dyes.** Imperial Chemical Industries Ltd., Norman H. Haddock and Frank Lodge. Brit. 394,312, June 13, 1933. The dyes are prepd. by causing to react an amino-3-keto-2,3-dihydrobenzo-1,4-thiazine with a 1-hydroxyanthraquinone, or a leuco deriv. thereof, oxidizing, if necessary, and hydrolyzing the product to give the substituted thioglycolic acid of which it is the lactam. The 1-hydroxyanthraquinone may carry substituents. Among examples (1) leucoquinazarin is condensed with 7-amino-3,4-dio-2,3-dihydrobenzo-1,4-thiazine (I) in pyridine in presence of  $\text{H}_2\text{BO}_3$  and saponified with aq.  $\text{NaOH}$  to yield the thioglycolic acid which dyes wool green shades and (2) leuco-1,1,5-trihydroxyanthraquinone is similarly condensed with I; the dyeing shade after lactamization is green. I is prepd. by hydrolyzing (alk.) the 6-amino-benzothiazole according to Brit. 355,808 (C. A. 26, 5573), treating the resulting mercaptophenylenediamine with chloroacetic acid and ring-closing by means of hot dil. mineral acid.

**Polymethine dyes.** I. G. Farbenind. A.-G. Fr. 749,331, July 22, 1933. Sym. and asym. polymethine dyes, the central atom of which is substituted, are prepd. by causing quaternary N bases having a reactive Me group in the *o*-position to react with an alkyl ester of an arylated thioamide acid, preferably in the presence of condensation agents and solvents. The reaction may be carried out in 2 steps, the condensing agents for the 1st being acids or anhydrides, e. g.,  $\text{Ac}_2\text{O}$ , and the condensing agents for the 2nd being bases, e. g., pyridine or piperidine. The intermediate product may be isolated and condensed with another quaternary  $\text{NH}_4$  salt. The products are used for sensitizing photographic emulsions. Examples are given.

of the prepn. of the iodide or perchlorate of 1,1'-diethyl-meso-methyl-, 1-ethyl-1'-methyl-6',7'-benzo-meso-methyl-, 1,1'-diethyl-6'-diethylamino-meso-methyl-, 1,1'-diethyl-4',5'-benzo-meso-methyl-, 1-ethyl-1'-methyl-6',7'-benzo-meso-ethyl-, 1,1'-diethyl-meso-ethyl-, 1,1'-diethyl-4',5'-benzo-meso-ethyl-, and 1-methyl-1'-ethyl-4',5'-benzo-meso-ethylbenzothiocarbonyl-, 1,1'-diethyl-meso-methyl-, 1,1'-diethyl-6,6'-dimethoxy-meso-ethyl-, 1,1'-diethyl-6'-methoxy-meso-ethyl-, 1,1'-diethyl-6,6'-dimethoxy-meso-ethyl- and 1,1'-diethyl-6,6'-dimethoxy-meso-methoxyphenyl-benzoselenocarbonyl-, 1,1'-diethyl-6'-diethylamino-meso-methyl-, 1,1'-diethyl-6',7'-benzo-meso-methyl-, 1,1'-diethyl-meso-ethyl-, 1,1'-diethyl-6',7'-benzo-meso-ethyl- and 1,1'-diethyl-6'-methoxy-meso-ethyl-benzoselenocarbonyl- and 1,1'-diethyl-meso-ethylbenzothiocarbonyl- and 1,1'-diethyl-meso-ethylbenzothiocarbonyl- Cf. C. A. 27, 3618.

**Dyes of the pyranthrone series.** Ronald S. Barnes, John E. G. Harris, Birkett Wylam and John Thomas (to Scottish Dyes, Ltd.). U. S. 1,929,912, Oct. 10. A sulfuric ester of brominated pyranthrone is formed by heating brominated pyranthrone, pyridine- $\text{SO}_2$  and pyridine, gradually adding finely divided Cu, adding NaOH and sepg.

**Stilbene dyes.** Soc. pour l'ind. chim. à Bâle. Ger 583,036, Aug. 31, 1933. See Brit. 348,283 (C. A. 26, 5215).

**Acid wool dyes (anthraquinone series).** I. G. Farbenind. A.-G. Brit. 393,631, June 9, 1933. Anthrapyrimidone compds. are obtained by causing a 1-aminoanthraquinone-2-sulfonic acid, or salt thereof, substituted in the 4-position by an alkylamino, arylamino, aralkylamino or hydroalkylamino group, to react with a urea, alkylurea or urethan at an elevated temp. (150-200°), preferably in a solvent for both components, e. g., PhOH, and in the presence of condensing salts. Among examples 1-amino-4-methylaminoanthraquinone-2-sulfonic acid (I) or the corresponding 1-hexahydroamino compd. is treated with Me or Et urethan. In 393,632 the above sulfonic acids, in which the 5-8 positions may be substituted in particular by halogen or HSO group, are condensed with a malonic acid dialkyl ester at an elevated temp., preferably in presence of a solvent for both reactants and in the presence of an alk. reagent, to form O-carbalkoxyanthrapyridones. Among examples I is condensed with malonic acid di-methyl ester.

**Acid wool dyes of the anthraquinone series.** Georg Kalscher, Ernst Honold, Heinrich Klingenstein and Karl Dörmann (to General Aniline Works). U. S. 1,927,125, Sept. 19. Dyes gradually producing blue or greenish blue shades on wool from an acid bath (these shade being generally more bluish and of better leveling properties than in the case of the starting material) are produced by treating with acylating agent a 1-amino-4-aryl-aminoanthraquinone-2-sulfonic acid in which the 4-aryl-amino group is  $\text{NH-R-NH}_2$ , where R means a residue of the benzene series and N H, alkyl or cycloalkyl. Suitable acylating agents are for instance acid anhydrides, carboxylic or sulfonic acid chlorides such as acetyl chloride, mono- and di-chloroacetyl chloride, acetic anhydride, benzoyl chloride, benzenesulfonyl chloride, phthalic anhydride. When an acid chloride is used, an acid-binding agent may be added with advantage. The process may be carried out either in an aq. medium or by using dried starting materials in an org. solvent particularly an org. base. Several examples with details of procedure are given. Cf. C. A. 27, 6078.

**Wool dyes of the anthraquinone series.** Ernst Honold and Klaus Weinand (to General Aniline Works). U. S. 1,928,725, Oct. 3. Dyes are obtained by condensing a 1-hydroxy-4-haloanthraquinone-2-sulfonic acid with a compd. which contains an exchangeable hydrogen atom linked to nitrogen and corresponds to the general formula  $\text{P-NH}_2$ , wherein R represents alkyl, cycloalkyl, aralkyl, aryl or acyl. The addition of a catalyst, such as Cu or a Cu salt, facilitates the reaction. The same effect is also produced by the application of the Cu salt of the 1-hydroxy-4-haloanthraquinone-2-sulfonic acid which is prepd. by heating 1-diazo-4-haloanthraquinone-2-sulfonic acid with Cu or a Cu salt as described in U. S. Patent No. 1,888,017 (C. A. 27, 1364). The new dyes show good fastness. Their shades vary according to the nitrogen compds. applied; aromatic and aliphatic amines yield violet to blue dyes, whereas reddish products are obtained by using acid amides. Several examples with details of procedure are given.

**Sensitizing dyes.** I. G. Farbenind. A.-G. Brit. 394,537, June 20, 1933. See Fr. 731,508 (C. A. 27, 5014).

**Reduction products of dyes of the indigo series.** I. G. Farbenind. A.-G. Brit. 395,183, July 13, 1933. Stable reduction products of halogen derivs. of indigo, indirubin and their homologs are prepd by heating the leuco compds. of the dyes, wholly or substantially in the free form and dispersed in aq. or  $\text{H}_2\text{O}$ -contg. media, until they are converted wholly or substantially into compds. that are difficultly sol or insol. in cold aq. solns. of caustic alkalis.

The dyes may be reduced in alk., neutral or acid media and the free leuco compds. may be heated, simultaneously or subsequently or after isolation, either alone in aq. or  $\text{H}_2\text{O}$ -contg. media or with acid agents. Among examples (1) 5,5',7,7'-tetrachloroindigo is boiled in alc. with  $\text{HCOONH}_4$  and  $\text{SO}_2$  until a stable reduction product seps and (2) 5,5',7,7'-tetrabromoindigo is heated in aq. alc with  $\text{Na}_2\text{S}_2\text{O}_4$  and after reduction the soln. is boiled; or the dye is treated in very dil. alkali soln. in presence of a Ni catalyst with H under pressure at about 90°; or the dehydroacetate deriv. is boiled in alc with  $\text{HCOONH}_4$  and  $\text{NH}_4\text{HSO}_4$  soln. The products are stable in air and may be dried without special precautions; they dissolve in hot alkali solns. and in cold alc. alkali solns. to give the ordinary leuco compds. into which they may also be converted by steaming (when worked up as printing pastes).

**$\alpha$ -Amino carboxylic acid esters of the anthraquinone series.** Karl Wilke (to General Aniline Works). U. S. 1,929,803, Oct. 10. Dye intermediates are obtained by causing an anthraquinone-1,2-isoxazole to react with a compd. of the general formula  $\text{R-OH}$  in which R represents an alkyl or an aryl group of the benzene series, in the presence of KCN or Na methylate. Details are given of the production of the 1-aminoanthraquinone-2-carboxylic acid methyl, ethyl and phenyl esters, m. 228°, 198° and 198°, resp.

**Aromatic condensation products.** I. G. Farbenind. A.-G. (Hans Schlichtmaier, inventor). Ger 576,964, May 22, 1933. These are produced by action of 1 mol. of a *p*-nitro amine of the general formula  $\text{H}_2\text{N-Ar-NO}_2$  on 2 mols. of an arylsulfonic acid in soln or suspension. Thus, 1-methyl-2-amino-4-methoxy-5-nitrosobenzene is treated with *p*-toluenesulfonic acid to give a product m. 233-4°. The products are useful as dye intermediates.

**Anthraquinone derivatives.** Henry Dravins. Fr. 750,639, Aug. 14, 1933. Alkyl or other substituents are introduced into the *m*-positions of arylamino groups of arylaminoanthraquinones to form new dyes which have an increased affinity for cellulose esters and ethers. Examples of dyes mentioned are 1-hydroxy-4-, 1-amino-4-, 1-methylamino-4-, 1,5-diamino-4,8-di-, dihydroxy-4-, 1-amino-4,8-dihydroxy-5- and 1-amino-5-hydroxy-4-m-tolylaminoanthraquinone, also 1-amino-4-(5'-methyl-2'-methoxyphenylamino)-, 1-hydroxy(or amino)-4-(3'-methyl-4'-acetvlaminophenylamino)-, 1-amino-4-(2',5'-dimethylphenylamino)- and 1-amino-4-(3',5'-dimethylphenylamino)-anthraquinone.

**Halogenated substances.** I. G. Farbenind. A.-G. Karl Keller and Ferdinand Munz, inventors. Ger. 576,710, May 18, 1933. Higher satd. or unsatd. aliphatic acid- or hydroxy aliphatic acids are treated with sufficient Cl to replace at least one H atom in the unsatd. acids and at least 2 in the satd. acids. The chlorination is carried out in the usual way in the presence of an org. diluent. In an example, ricinoleic acid is treated with sufficient Cl to replace 3 H atoms. The products are useful as auxiliaries in dyeing, and for other tech. purposes.

**Nitrogen-containing cyclic ketones.** Heinrich Greune, Wilhelm Fekert, Heinrich Sieber and Gerhard Langbein (to General Aniline Works). U. S. 1,931,192, Oct. 17.

**Dye intermediates** are obtained by causing a compd. of the formula  $\text{NCCH}_2\text{COOX}$  in which X stands for H, an alkali metal or an alkyl group to react, first at a temp. of about 70-140° and then at about 150-190°, upon a polynuclear aromatic compd. of the acenaphthene, naphthalene or anthracene series contg. at least one pair of free *peri* positions in the presence of an acid-condensing agent such as  $\text{AlCl}_3$  mixed with  $\text{NaCl}$ ,  $\text{KCl}$  and  $\text{NaF}$ . When using acenaphthene and cyanoacetic acid as initial materials, the reaction probably proceeds in such a manner that the cyano group is first added to the hydrocarbon and the monoketimide of the *peri*-indandione is then formed with the elimination of water and alc., resp. Various other examples are given and products formed which correspond

with the general probable formula  $\text{CH}_2\text{---}\overset{\text{---}}{\text{C}}\text{---}\overset{\text{---}}{\text{C}}\text{---}\overset{\text{---}}{\text{C}}\text{---}\overset{\text{---}}{\text{C}}\text{---}\text{NH}$ ,

where the C atoms  $\text{C}_1$ ,  $\text{C}_2$  and  $\text{C}_3$  are members of an aromatic grouping of the naphthalene or anthracene series,  $\text{C}_1$  and  $\text{C}_2$  representing C atoms occupying the *peri*-positions of said grouping, are considered as new products. They are generally obtained in the form of their salts especially the hydrochlorides, but the corresponding free imides may easily be obtained therefrom by a treatment with alkali.

**Dyes and intermediates of the anthraquinone series.** Wm. Smith, Sidney Thornley and Robert P. Thomson (to Imperial Chemical Industries Ltd.) U. S. 1,929,875, Oct. 10. Aroylated triaminoanthraquinone dyes which dye green shades turned to red by oxidizing are formed by mononitrating 1,4-diphthalimidanthraquinone, removing the *N*-phthaloyl groups by hydrolysis, reducing the nitro group to an amino group, and causing the product to react with an aroylating agent such as benzoyl chloride.

**Dyes and intermediates.** Soc. pour l'ind. chim. à Bâle. Brit. 393,271, May 17, 1933. Intermediates that couple with diazo compds. or condense with aldehydes to form dyes and have the formula  $\text{RCONHR}'(\text{NHCOR}')_n$ , in which R is the residue of any aromatic carboxylic acid contg. a  $-\text{COCH}_2$  group that can couple with diazo compds. or condense,  $\text{R}'$  the residue of any aromatic carboxylic acid that can couple with diazo compds.,  $\text{R}''$  the residue of an aromatic diamine or polyamine and  $n$  a whole no., are obtained by acylation of the amines with the acids. Among specified amines are *m*- and *p*-phenylenediamines; tolylenediamines, halogenated phenylenediamines; anisylendiamines; phenylethylenediamines, naphthylenediamines; benzidine; tolidines, bisanilines, biphenetidines; *o,p'*-, *o,p''*- and *p,p'*-diaminodiphenyl ethers, e. g., 2,4,4'-triaminodiphenyl ether; and generally diamines and polyamines in which (un)substituted aromatic residues are connected by bivalent connecting members such as  $\text{O}$ -,  $\text{S}$ -,  $\text{CH}_2$ -,  $-\text{NH}$ -,  $\text{NHCO}$ -,  $\text{N}=\text{N}$ -, azoxy,  $\text{NHCONH}$  or a heterocyclic residue, such as triazine and pyrimidine residues, and diamines and triamines derived from complexes contg. condensed heterocyclic and aromatic nuclei, e. g., dehydrothiophthalidines, dehydrothiopyridines contg. further amino groups, diamino- and polyamino-dibenzimidazoles, dibenzoxazoles and dibenzotriazoles. Specified acids contg. the  $\text{COCH}_2$  group are the 1-aryl-5-pyrazolones carrying a  $\text{COOH}$  group in the aryl nucleus (obtained by condensing hydrazines derived from amino carboxylic acids such as *m*- or *p*-aminobenzoic acids, aminotoluic acids, etc., with acetoacetic or oxaloacetic esters), the acetoacetic arylides carrying a  $\text{COOH}$  group in the aryl nucleus, the arylbarbituric acids carrying a  $\text{COOH}$  group in the aryl nucleus, e. g., 3-carboxyphenylbarbituric acid, derivatives of benzoylacetone carrying nuclear  $\text{COOH}$ , e. g., benzoylacetone-*o*-carboxylic acid. Other specified aromatic carboxylic acids that can couple are hydroxy carboxylic acids of the  $\text{C}_6\text{H}_5$  series, especially those, e. g., *p*-cresotic acid, coupling in *o*-position to the OH group, hydroxynaphthalene-carboxylic acids, e. g., 2,3-hydroxynaphthoic acid and its 7-methoxy and 6-phenylamino derivs., hydroxycarbazole-carboxylic acids, hydroxyphenanthrene-carboxylic acids, hydroxynaphthocarbazole-carboxylic acids and hydroxydiphenylaminocarboxylic acids. The products are sol in

alkalies and may be absorbed from the solns. by animal or vegetable fibers. Dyes specified as obtainable by condensation with aldehydes are the condensation products from benzidine, symmetrically diacylated with 1-(3'-carboxyphenyl)-3-methyl-5-pyrazolone, and (a) benzaldehyde and (b) dimethyl-4-aminobenzaldehyde. The azo dyes obtainable by coupling with diazo compds. from unsulfonated amines, diazotized nitroanilines, diazoazo compds., diazotized aminodiphenylamines, *o*-hydroxy- and *o*-carboxydiazo compds. are described and examples are given.

**Dye intermediates.** I. G. Farbenind. A.-G. Brit. 395,152, July 13, 1933. *p*-Aminobiphenyl and derivs. thereof are obtained by the reaction of (halogenated) hydrocarbons of the  $\text{C}_6\text{H}_5$  series with *N*-haloacylamino compds. of the  $\text{C}_6\text{H}_5$  series in the presence of halides having a condensing action, e. g.,  $\text{AlCl}_3$ ,  $\text{FeCl}_3$ , with or without an org. diluent and with exclusion of  $\text{H}_2\text{O}$ , followed by sapon. of the acetylaminobiphenyl compd. formed. Among examples the following compds. are condensed in presence of  $\text{AlCl}_3$ : (1) *N*-chloroacetanilide with  $\text{C}_6\text{H}_5$  and with  $\text{C}_6\text{H}_5\text{Cl}$ , the latter yielding the 4'-chloro compd., (2) *N*-chloroacetyl-*o*-toluide (I) with  $\text{C}_6\text{H}_5$ ; the product gives on oxidation 3-carboxy-4-acetamidobiphenyl which is saponifiable to 3-carboxy-4-aminobiphenyl, (3) *N*-chloropropionylanilide with  $\text{C}_6\text{H}_5$  and (4) I with  $\text{PhMe}$ .

**Dyeing.** British Celanese Ltd. and George H. Ellis. Brit. 391,317, June 9, 1933. In producing azo dyes on textile materials (cellulose esters and ethers and animal fibers) by fixing the diazo and (or) coupling component in the free state on the material prior to color formation the fixation is effected by applying aq. dispersions or suspensions of the component(s) by mech. impregnation and subjecting the material to a moist heat treatment, e. g., steaming. The fixation and subsequent development may be effected continuously. Among examples (1) cellulose acetate is padded with a dispersion of *p*-aminobenzeneazo- $\alpha$ -naphthylamine, dried, steamed, diazotized and developed with a dispersion of  $\beta$ -hydroxynaphthoic acid and (2) a natural silk fabric is padded with a dispersion contg. the anilide of 2,3-hydroxynaphthoic acid and 5-nitro-2-aminidine, dried, steamed and developed.

**Dyeing organic derivatives of cellulose.** Wm. Whitehead (to Celanese Corp. of America). U. S. 1,929,573, Oct. 10. Fabrics or films of materials such as cellulose acetate are sprayed with a compn. contg. a water-insol. dye dissolved in an org. liquid such as ethylene dichloride which is a swelling agent for the cellulose deriv. Cf. C. 1. 27, 5980.

**Dyeing rayon.** Soc. pour l'ind. chim. à Bâle. Ger. 581,162, Sept. 20, 1933. Piece goods of viscose rayon are dyed in uniform blue shades with dyes prepd. by coupling in an alk. medium 1 mol. of tetrazotized 4,4'-diaminobiphenyl, or its derivs. substituted in the 3- and 3'-positions with alkyl or alkoxy groups, with 1 mol. of 1-naphthol-4,8-disulfonic acid and 1 mol. of a 1-amino-8-naphtholsulfonic acid or a 2-amino-5-naphtholsulfonic acid. An example is given.

**Dyeing materials such as cellulose acetate.** George H. Ellis, Tobias Ockman and Henry C. Olpin (to Celanese Corp. of America). U. S. 1,930,232, Oct. 10. The fastness of colorations such as those produced by anthraquinone derivs. on cellulose acetate is improved by incorporating in the materials, at any stage of their manuf., an alkylated aminodiphenyl base such as tetramethyldiaminodiphenylmethane having itself no coloring action on the material.

**Dyeing, sizing or impregnating paper during manufacture.** I. G. Farbenind. A.-G. (Kuno Franz, inventor). Ger. 580,813, July 17, 1933. Added to 546,270 (C. A. 27, 1925). Modifications of the invention of Ger. 546,270 are described.

**Dyeing and printing.** I. G. Farbenind. A.-G. Brit. 393,408, June 8, 1933. Insol. azo dyes are made on the fiber by treating the material with an azo dye prepn., adding in an acid soln. and developing by passing over heated drying cylinders or through a heated chamber or by lawing through a container filled with steam. The

process is used for printing with azo preps. alone or together with printing by means of ester salts of leuco vat dyes and for the production of colored resists under dyeings from aniline black preps. and (or) ester salts of leuco vat dyes. Among examples (1) a fabric is printed with a mixt. of the diazoamino compd. from 4-chloro-2-toluidine and 4-sulfo-2-aminobenzoic acid with diacetoacetyl-*o*-folidine (I), dried, padded on the reverse side with an acid soln. contg. 1 or more org. acids,  $H_3PO_4$ , 1 or more easily dissociated metal salts of inorg. acids or 1 or more salts capable of yielding acid, *e. g.*,  $NH_4$  salts of org. acids, or mixts. of these, and then directly dried on a cylinder drying machine and finished, and (2) a fabric is printed with a prepn. contg. the nitrosoamino Na salt of 5-chloro-2-anisidine,  $NaOH$ ,  $NaOAc$  and I or 2',3'-hydroxynaphthyl-*o*-anisidine and finished as in (1). Cf. C. A. 27, 1767.

**Dyeing and printing.** Oranienburger chem. Fab. A.-G. and Kurt Lindner. Ger. 582,378, Aug. 14, 1933. In dyeing or printing animal or vegetable materials with mordant dyes, the mordants used are salts of mordant metals with alkyl-substituted aromatic sulfonic acids, *e. g.*, hexadecyltoluene- or aminonaphthalene-sulfonic acids. The salts may be formed *in situ* from an alkali sulfonate and an inorg. mordant metal salt. The mordants are preferably used in assocn. with a water-sol. mono- or poly-hydric alc. Examples are given. Cf. C. A. 26, 5769.

**Printing with vat dyes.** Bleachers' Association Ltd., Charles S. Parker, Charles L. Wall and Franklin Farrington. Brit. 393,381, June 8, 1933. Pattern effects are obtained with leuco esters of vat dyes by treating a fabric, prior to application of the ester, in selected areas with a resist contg. reagent(s), *e. g.*, readily reducible mineral acid salts of heavy metals such as Fe or Cu, serving to hydrolyze and oxidize the ester before absorption of the ester by the fabric can take place. In an example a silk or cotton fabric is printed with a resist paste contg.  $CuSO_4$ ,  $Al(OAc)_3$ , and locust bean thickening, dried, padded in an aq. soln. contg. Soldon jade green paste and  $Na_4Fe(CN)_6$ , dried again, steamed 30-60 min., oxidized in  $H_2O_2$  and mineral acid and soaped. In the case of silk fabric the residue may be removed from the resisted areas by treatment with  $NH_4$  and oxalic acid. Cf. C. A. 27, 4418.

**Printing textiles.** I. G. Farbund. A.-G. Brit. 394,632, June 29, 1933. Vat or other alk. printing or discharge pastes are made suitable for use on wool by incorporating therewith ammonoacetic acid or a salt thereof. Among examples (1) wool is printed with an aq. paste contg. Indigo pure BASF, glycerol, gum thickening,  $K_2CO_3$ , Na formaldehyde sulfoxylate and Na ammonoacetate, dried, steamed 5 min., exposed to air, passed through a bath contg. Na perborate and  $AcOH$ , rinsed, soaped and dried and (2) woolen goods, dyed with Naphthol blue-black S, are printed with an aq. discharge paste contg. the vat dye Hydron orange R and other ingredients as in (1) and finished. Cf. C. A. 27, 2313.

**Printing fabrics.** I. G. Farbefund A.-G. (Richard Fischer and Hermann Freund, inventors). Ger. 571,355, Apr. 13, 1933. Addn. to 562,023 (C. A. 27, 1206). Fabrics are printed or reserve-printed on the fiber with insol. azo dyes, and slop-padded or printed with vat dyes from ester salts of leuco vat dyes after the manner of 562,023. An oxidizing agent such as  $NaNO_2$  or a neutral chromate soln. is added to the slop-padding paste. Oxide, hydroxide or carbonate of an alk. earth metal or of Mg and Zn and a mild reducing agent such as  $Na_2S_2O_4$  is added to the printing paste. The dried fabric is then treated with dil. org. acid or with  $H_2PO_4$ , or with easily dissoci. salts such as  $(NH_4)_2SO_4$ . The fabric is then finally dried. In an example, fabric is slop-padded with a paste contg. the  $H_2SO_4$  ester of a blue dye, ethylenethiodiglycol, water,  $NaNO_2$ ,  $NH_4OH$  and tragacanth thickening. The fabric is then printed with a paste contg. the yellow dye No. 3 of the table appended to Ger. 584,040 (C. A. 26, 1133), water,  $NaOH$ , denatured alc., tragacanth thickening,  $ZnO$  and  $Na_2S_2O_4$ . The printed fabric is then washed in a soln. contg.  $(COOH)_2$ ,  $HCOOH$  and  $Na_2SO_4$ . The dried fabric then shows a yellow pattern on a blue background. Other examples are given.

**Printing fabrics.** I. G. Farbenind. A.-G. (Hermann Freund, inventor). Ger. 583,316, Sept. 6, 1933. A fabric is printed with a paste contg. a substantive azo dye component, a water-sol. diazoamino compd., an alkali, and a reserve for ester salts of leuco compds. of vat dyes, *e. g.*,  $ZnO$  or  $MgO$ , with or without a mild reducing agent, *e. g.*,  $Na_2S_2O_4$ . The fabric is then printed in another design with a paste contg. an ester salt of a vat dye leuco compd., an oxidizing agent, *e. g.*,  $NaClO_2$ , a reagent which yields a nonvolatile acid, *e. g.*, an  $NH_4$  salt of  $HCNS$ ,  $(COOH)_2$ , citric or tartaric acid, and an oxidation catalyst, *e. g.*,  $NH_4$  vanadate. The fabric is then steamed, whereupon the parts covered by both pastes are colored by the azo dye from the first paste, the parts covered by the second paste only are colored by the vat dye from the second paste, and the parts covered by the first paste only remain undyed. The fabric is finally washed and soaped. The process may be modified by replacing the vat dye deriv. in the second paste by an aniline black compn. or other compn. which yields a dye on oxidation, and in this case the second paste may contain free nonvolatile org. acids as well as reagents yielding such acids. Numerous details are given.

**Printing silk.** Durand & Huguenin A.-G. Ger. 583,204, Aug. 31, 1933. See Brit. 387,297 (C. A. 27, 4689).

**Coloring textiles.** Henry Dreyfus. Fr. 749,364, July 22, 1933. Colors are discharged or the fixation of a color is prevented by a discharging compn. in the presence of an org. base, *e. g.*, urea or dimethylurea. Fr. 749,365. In producing discharge effects on materials composed of or contg. cellulose esters, the materials are saponified after being colored by the foundation color but before the discharge of this color. The sapon. is carried out to a degree such that cellulose acetate loses 5-15% of its wt.

**Coloring organic cellulose derivatives such as cellulose acetate.** Wm. A. Dickie and Frank B. Hill (to Celanese Corp. of America). U. S. 1,930,226, Oct. 10. Finely divided particles are incorporated in the material by exposing it to a high-velocity particle stream formed by disintegration of a mordanting metal such as Zn and some of these particles are oxidized during their transit to the material. A mordant dye is then applied, such as alizarin blue A.

**Discharge printing.** Frederick B. Downing and Richard G. Clarkson (to E. J. du Pont de Nemours & Co.). U. S. 1,931,108, Oct. 17. A discharge compn. contg. guanidine thiocyanate is printed on dyed cellulose acetate material and the discharge operation is finished by aging at about 100°, washing and drying.

**Dyeing apparatus.** Joseph Annicq. Brit. 394,900, July 6, 1933.

**Yarn-printing machine.** Henry F. Shaffner (to Briggs-Shaffner Co.). U. S. 1,930,986, Oct. 17. Structural and mech. features.

**Treating textile fibers.** Johann G. Kästner. Ger. 584,313, Sept. 18, 1933. Addn. to 553,047 (C. A. 26, 4723). An aq. carob-bean ext. contg. a hygroscopic substance, *e. g.*,  $MgSO_4$  or glycerol, is applied to textile fibers consisting of or contg. cotton, before they are spun into fine yarns. The hygroscopic substance may be replaced wholly or in part by a water-sol. oil, *e. g.*, Turkey-red oil.

**Treating fibrous materials, e. g., textiles, paper, leather, etc., with liquids.** Erba Fabrik chemischer Produkte Spezialitäten für die Textilindustrie. Brit. 394,816, July 6, 1933. See Fr. 739,214 (C. A. 27, 2045).

**Vegetable textiles.** Heberlein & Co. A.-G. Fr. 749,117, July 18, 1933. Textiles, particularly cotton and viscose silk, are improved by submitting them, at any desired point of their manuf., to a treatment with compds. of bi- or polyvalent metals and with natural or artificial resins or lacquers. Compds. of Al, Zr, Sn, Ti or Zn may be used and the artificial resins may be produced in the textiles.

**Composition for cleaning and purifying animal and vegetable fibers.** Carl Ludecke and Wilhelm Wilcken. U. S. 1,927,839, Sept. 26. An emulsion miscible with water comprises an aq. soln. of an acid used as the dis-

persion medium such as a soln. of oxalic or tartaric acid together with a volatile water-immiscible org. fat solvent such as benzine and  $C_2H_5Cl$  as the dispersed substance, and a vegetable mucous substance such as tragacanth and Irish moss serving as a thickening medium and stabilizer and sour milk.

**Crepe rayon threads.** Claude Clémeucon. Brit. 394,793, July 6, 1933. To avoid the necessity for sizing and to permit the use of the usual twisting machines viscose rayon, previous to the hard twisting necessary for creping, is subjected to a shrinking by treatment with a swelling agent so that the breaking elongation is increased or the process of manuf. is conducted so as to produce a thread of similarly high elongation by avoiding tension during the spinning operation. A soln. of NaOH may be used for the shrinking and  $Na_2S$  may be added thereto to effect desulfurization at the same time. Cf. C. A. 27, 3317.

**Lustrous effect threads.** Alfred Rheiner (to Chemische Fabrik vorm. Sandoz). U. S. 1,926,498, Sept. 12. For the prepn. of lustrous effect threads having no affinity for substantive dyes and consisting of the lower acetylated derivs. of cellulose, by the direct acetylation of mercerized cellulosic fibers without altering the phys. character of the fibers, the reaction is effected in a single acetylating bath and the fibers are immersed in a quantity of acetylating mixt., contg. glacial HOAc, an acetylation catalyst such as  $ZnCl_2$  and an excess over the theoretically required amt. of  $Ac_2O$ , which entirely covers the material during the reaction, and the reaction is allowed to proceed only until mono- and di-acetyl derivs. of cellulose are formed, and care is taken that during the reaction no local superheating occurs and that the temp. of the mass is uniform. Cf. C. A. 26, 3919.

**Processing fabrics.** Camille Dreyfus and Herbert Platt (to Camille Dreyfus). Can. 335,669, Sept. 12, 1933. Fabrics or yarns made of, or contg., org. esters of cellulose are treated with a saponifying bath contg. an alk. soln. of comparatively high concn. preferably at low temp. The fabric may then be dyed with suitable dyes. The saponifying bath may contain any suitable alkali such as NaOH, KOH or  $NH_3$ . The concn. of the alkali soln. is preferably 5-20% by wt. The saponifying bath may also contain such assistants as ales. or  $AcONa$ , e. g., material contg. cellulose acetate is treated with an alk. soln. corresponding to a NaOH soln. of 5-20% concn. at 35°. The treated fabric is dyed with a cotton dye and then printed with a discharge paste contg. a reducing agent.

**Dressing textiles.** I. G. Farbenind. A.-G. (Herbert Gensel, inventor). Ger. 579,913, July 5, 1933. Addn. to 561,178 (C. A. 27, 1208) and 553,174 (C. A. 26, 4724). Textiles are treated with a compn. contg. starch or other usual dressing agent, an aldehyde, e. g.,  $CH_2O$ , and a polymerization product of the kind described in Ger. 553,174. The textiles may then be heated to about 70°. Dressings fast to washing are obtained. Examples are given. Cf. C. A. 27, 2045.

**Saponification of the surface of fabrics containing cellulose esters.** Camille Dreyfus and Herbert Platt (to Camille Dreyfus). Can. 335,670, Sept. 12, 1933. A soln. of alkali is padded onto a fabric contg. yarns of org. esters of cellulose in such a manner that alkali in amt. equal to 3-12% of caustic based on the wt. of the fabric is applied to the fabric. The fabric is dried on heated drums and then thoroughly washed. The safe ironing point of the fabric is materially increased and the yarns are intensely saponified on the surface. The alk. soln. may contain alkalis as NaOH or KOH. If desired these alkalis may be replaced in whole or in part by suitable alk. salts as  $Na_2CO_3$  or  $K_2CO_3$ , Na or K silicate, Na or K sulfide.

**Composition for treating silk and rayon fabrics.** Frank P. Miller. U. S. 1,929,705, Oct. 10. An aq. mixt. suitable for impregnating hosiery fabrics in order to strengthen them is formed from alum 70 and boric acid 27 parts to which may be added about 3 parts of gum arabic with a smaller proportion of salt and casin.

**Fibroin solutions.** I. G. Farbenind. A.-G. Brit. 394,212, June 22, 1933. Fibroin is dissolved in a soln. of a

mixt. of 2 or more hydrated salts, e. g., the thiocyanates of Na, Mg, Ba, Li, Mn and Zn. Acid amides may be present according to the process of Brit. 375,242 (C. A. 27, 4100). The soln. obtained may be purified by dialysis and used in the prepn. of spinning solns. or plastic masses.

**Apparatus for coating fabrics for tarpaulins, etc.** Nagapa C. Tambrali. Brit. 394,860, July 6, 1933.

**Apparatus for the wet treatment of textiles on bobbins.** Zittauer Maschinenfab. A.-G. (Alwin Schwenke, inventor). Ger. 580,694, July 14, 1933. Addn. to 484,228 (C. A. 24, 975).

**Tentering and drying machine for fabrics.** Emile Prat. Brit. 394,521, June 29, 1933.

**Decomposition products of albumin.** Chemische Fabrik Grunau Landshoff & Meyer A.-G. Fr. 749,228, July 20, 1933. Decomposition products of high mol. wt. from albumin, particularly those of the type of lysalbinic and protalbinic acids are given new properties by treating them with fatty acids, said or not, of high mol. wt. or their substitution products or derivs. The products obtained may be used in washing, dyeing or mercerizing baths and for treating textile fibers and leather.

**Washing and decolorizing textile materials.** Victor Weerts, Jr. and Maximine Soc. anon. Brit. 394,871, July 6, 1933. See Belg. 384,611 (C. A. 26, 6159).

**Desizing and bleaching textiles.** De Fibergesche Stoombleekery voorheen de Firma G. J. Ten Cate & Jonen. Brit. 395,306, July 13, 1933. Textiles are desized and bleached by treatment under pressure with an enzyme bath and the usual bleaching baths, said baths being successively circulated through the material in the same vessel. App. is described. The walls thereof are of manifold. App. or lined with an alloy contg. Fe, Cr, Ni, C and not less than 2% Mo, e. g., an Fe alloy contg. Cr 18, Ni 8, C 0.15 and Mo 34%.

**Delustering rayon.** Imperial Chemical Industries Ltd. and Leslie G. Lawrie. Brit. 393,985, June 19, 1933. Rayon comprising cellulose acetate or other acyl, alkyl or aralkyl deriv. of cellulose is delustered by treatment at an elevated temp. with an emulsion, of less than 5% concn., of pine oil, i. e., an oil in which terpenols are the main constituents. A powerful wetting and swelling action is exerted by the oil which assists the penetration of dyes. Among examples 10 lbs. of cellulose acetate or benzyl-cellulose rayon is delustered by treating 0.5-0.75 hr. at 80-90° in a bath contg. in 20 gals. of water 2 lbs. of an emulsion of pine oil 25, turkev red oil 25 and  $H_2O$  50 parts. Sulfonated fish oils and highly sulfonated castor oil are also specified as emulsifying agents.

**Delustering cellulose acetate.** Bleachers' Association Ltd. and Geo. D. Sutton. Brit. 394,332, June 21, 1933. Fibers or fabrics consisting of or contg. cellulose acetate are treated with  $H_2SO_4$  of preferably 3-6% concn. and, after removing the acid, the materials are delustered in known manner while under tension. When the delustering agent is a boiling soap soln. that contains a little  $PhOH$ , the delustered material may be finally washed with dil.  $NH_3$ . In 394,333, June 21, 1933, the delustering is carried out in known manner without applying tension.

**Mercerizing liquor.** Hermann Schuette (to I. G. Farbenind. A.-G.). U. S. 1,929,654, Oct. 10. An alk. mercerizing liquor is formed comprising a water-sol. salt of an acid sulfuric ester of an aliphatic alc. contg. from 4 to 8 C atoms, such as the Na salt of the acid sulfuric ester of hexyl alc. to reduce the surface tension of the alk. liquor.

**Mercerizing lyes.** I. G. Fabrik chemischer Produkte Spezialitäten für die Textilindustrie. Brit. 394,499, June 29, 1933. A naphthene and a phenol or a deriv. thereof, e. g., cresol, xylenol, chlorophenol, are added to mercerizing lyes. A small amt. of aliphatic ales., aromatic or hydrogenated aromatic compds. that increase the moistening power of the lyes may also be added. In examples cresol and naphthene alc. and cresol, naphthene alc.,  $BuOH$  and methyleyclohexanol are added.

**Combined mercerizing and neutralizing machine for yarns, etc.** Soc. Veuve Bonnet Aine et ses Fils. Brit. 394,906, June 22, 1933.

**Treating furs for extending or straightening the hair.**

Alexander Nathansohn. U. S. 1,931,355, Oct. 17. Skins such as those of sheep, etc. are treated with a substantially anhyd. lower aliphatic acid such as formic or acetic acid. Gasoline,  $C_6H_6$ ,  $CHCl_3$  or  $CCl_4$  may be used as solvents, and  $EtOAc$ , ethyl ether,  $EtOH$  or acetone act as retarders.

Rubber coated fabric. Wm. S. Gocher and Arthur N. Parrett (to E. I. du Pont de Nemours & Co.). U. S. 1,931,110, Oct. 17. A rubber-coated fabric is provided with a final baked coat of a compn. comprising asphalt oil (an unsatd. distillate or asphalt), pigment and drying oil, which serves to give good durability and weather resistance. Cf. C. A. 27, 631.

Rubberized fabric. Foster D. Snell and Aaron London (to Londat Agtz Fabric Co.). U. S. 1,929,368, Oct. 3. A transparent sheet of flexible material such as strained latex is cast upon a foundation layer of flexible open-work material such as lace so that the design of the latter remains visible through the overlying cast layer which fills the open portions of the design.

Kier suitable for boiling and finishing textile fabrics. Ethelbert A. Kusden and Kenneth S. Johnson (to Textile-Finishing Machinery Co.). U. S. 1,931,119, Oct. 17.

Various details are described of app. and of a liquid circulating system in which steam is injected into the central portion of the liquid in the kiers.

Wetting agents, etc. H. Th., Bohme A.-G. Brit. 393,769, June 15, 1933. The wetting, cleansing, foaming and dispersing power of liquids and plastic preps. used for treating textiles, leather or other fibrous materials is improved by the addn. of synthetically prepd. glucosides derived from sugars or polymeric carbohydrates and aliphatic alcs. having more than 5 C atoms, cycloaliphatic or aromatic alcs. or substitution derivs. thereof such as halogen, amino or carboxy derivs. The glucosides may be prepd. by known methods or directly from the sugar by treatment with a soln. of  $HCl$  in the alc. Starch is treated with  $HI$ ,  $AcBr$  and glacial  $AcOH$  to produce aceto-bromoglucose. Among examples a dye bath for cotton contains Sirius blue G,  $Na_2CO_3$ ,  $Na_2SO_4$ , the Na salt of lauryl sulfuric ester and lauryl glucoside and a spinning flux comprises an emulsion of olein, cetyl glucoside, Turkey-red oil and  $H_2O$ .

Wetting agents for textile fibers. Newport Chem. Corp. Ger. 583,475, Sept. 4, 1933. See Fr. 710,541. (C. A. 26, 1803).

## 26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

A century of progress in the paint industry. Geo. B. Heckel. *Paint, Oil & Chem. Rev.* 95, No. 20, 5-8, 18; *Am. Paint J.* 17, No. 51, 18 et seq., No. 52, 16 et seq. (1933).

Common sense in the paint and varnish industry. Wilhelm Krumhhaar. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 445, 520-32; *Paint, Oil & Chem. Rev.* 95, No. 22, 43 et seq. (1933).—The value of cooperative research is stressed.

Technical educational work in Great Britain. For the student in paint and varnish technology. Louis L. Drake. *Paint & Varnish Production Mgr.* 8, No. 5, 24-7 (1932); 9, No. 11, 32-4 (1933).—A brief account is given of the courses in paint and varnish technology of the Borough Polytechnic, London. A list of other institutions offering similar courses is given.

Casein in paint technology. Georg Zerr. *Farben-Ztg.* 38, 1250-90, 1314, 1338, 1360-1, 1469-70 (1933). The production of casein, methods of dispersing it and suitable pigments for casein paints are described.

Casein paints and casein emulsion vehicles. Gottfried Troger. *Farbe u. Lack* 1933, 472, 487-8, 499-500, 516.—The phys. and chem. properties of casein are reviewed. Types of casein suitable for use in paint, methods for dispersing it and preserving it from decompn., suitable pigments and uses for casein paint are given.

Red lead or iron oxide paint. J. Rinse. *Verfkromck* 6, 238-9 (1933).—Polemical (cf. Matthijsen, C. A. 27, 5655).

The degree of protection afforded wood against moisture by paint coatings. F. L. Browne. *Paint, Oil & Chem. Rev.* 95, No. 18, 9-12 (1933).—A summary of C. A. 27, 4423, with some newly arranged tables. The effectiveness of coatings on different woods was in the following order: So. white pine (best), No. white pine, Douglas fir and redwood. The vol. percentage of pigment in a paint, within the range 24-48%, has little effect on the permeability of the paint to moisture. Zn oxide seems to rank higher than white lead, other opaque pigments ranking next. Linseed oil paints increase in effectiveness during the first 6 months of exposure.

Valuation of paints for acoustical treatment. P. C. Atwood. *Am. Paint J.* 17, No. 53A, 8 et seq.; *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 445, 443-53; *Paint, Oil & Chem. Rev.* No. 22, 53 et seq. (1933).—Paint is not an acoustical corrective and must be applied with care in order not to reduce the sound absorption of acoustical surfaces. It must be of such consistency that the fine pores and holes are not filled or bridged over. Data from

various sources on the sound absorption of various surfaces before and after painting are assembled. Some tests by A. are also given.

The effect of high temperatures on some paint materials. Detroit Paint and Varnish Production Men's Club. *Am. Paint J.* 17, No. 53A, 18; *Paint, Oil & Chem. Rev.* 95, No. 22, 52, 92; *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 445, 505-7 (1933).—A no. of pigments and vehicles were subjected to gradually increasing temps. in an elec. muffle. Turps. causing changes in appearances or decompn. are given.

Accelerated weathering of paints and varnishes. V. G. Jolly. *J. Soc. Chem. Ind.* 41, 329-36T (1933).—Test panels were exposed continuously to light from a powerful C arc and intermittently to a cold water spray. For a wide variety of clear and pigmented oleoresinous products, this test gave failure of the same kind and in the same order as obtained with control panels on ordinary outside exposure. No quant. relationship existed, however, between life under accelerated and normal conditions, and results for compns. in which nitrocellulose predominated could not be correlated with the rest. Factors influencing the test (changes of temp. and humidity, type of supporting surface for film, intensity and wave length of ultra-violet light) are discussed.

Priming coat reductions for painting new wood surfaces. F. L. Browne. *Am. Paint J.* 18, No. 4, 19 et seq.; *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 445, 454-8; *Paint, Oil & Chem. Rev.* 95, No. 22, 67-8, 96 (1933). The condition of the tests described in C. A. 26, 1138, after 26 months is given. In general, the relative orders of failure of all paints on the 4 woods are the same, indicating that the optimum percentage of thinner (turps) is the same for all 4 woods. Many details regarding cleanliness, chalking, etc., are given.

The causes of and remedies for paint failures on plaster surfaces. Montreal Paint & Varnish Production Club. *Am. Paint J.* 17, No. 53B, 14-16; *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 445, 425-31; *Paint, Oil & Chem. Rev.* 95, No. 22, 71-3 (1933); cf. C. A. 27, 432.—Painting tests were conducted on plaster panels which included as one ingredient 0.1-2.0%  $Na_2SO_4 \cdot 10H_2O$ , equiv. to 0.03-0.50%  $NaOH$ . Including the  $NaOH$  introduced by the ingredients of the plaster, the max. amt. compatible with successful painting was 0.25%. Heat-bodied oils and  $S_2Cl_2$ -treated oils appeared to be the best vehicles. A high proportion of  $CaSO_4$  in the pigmented paints is desirable.

G. G. Sward

**A study of livering and its prevention by the use of catalysts.** Chicago Paint & Varnish Production Club. *Am. Paint J.* 17, No. 53B, 12-14; *Am. Paint & Varnish Mfrs'. Assoc. Circ.* No. 445, 450-69; *Paint, Oil & Chem. Rev.* 95, No. 22, 80 *et seq.* (1933).—The thickening of lithopone enamels contr. lined rosin-tung oil varnishes was proportional to the amt. of tung oil and acid value. Thickening was reduced by the addn. of small amts. of polar solvents, *e. g.*, cellosolve, and by dibasic and tri-basic org. acids, the latter being more effective. An attempt to predict the thickening tendencies of varnish by means of Gardner's alkali increase test was not successful. G. G. Sward

**Utilization of spirit of turpentine in paints.** G. Dupont. *Bull. inst. pin* 1933, 176. —The use of spirit of turpentine which has been aged several months is more economical than white spirit, even in relatively cheap paints for rolling stock, as the increased life of the paint more than offsets the difference in cost. A. Papineau-Couture

**Effect of China wood and fish oils in outside paints.** R. I. Kellam. *Am. Paint J.* 17, No. 53B, 16, 20, *Am. Paint & Varnish Mfrs'. Assoc. Circ.* No. 445, 477-80; *Paint, Oil & Chem. Rev.* 95, No. 22, 83-4 (1933).—Various properties of paints prep'd with linseed, tung, fish (pilchard) oils and mixts. thereof are noted and tabulated. Fish oil imparts to paints elasticity, blooming, non-yellowing and non-discoloration. Tung oil imparts gloss, a certain degree of shortness and yellowing. G. G. S.

**Accelerated tests for the settling of pigments in paints.** H. S. Werthan, R. H. Wien and B. A. Batzinger. *Ind. Eng. Chem.* 25, 1288-92 (1933); cf. *C. A.* 22, 2818. —Comparisons with actual shelf storage indicated that accelerated tests which involved storage at 65-70° with intermittent centrifuging tended to be too severe. Storage at elevated temp. is unnecessary, and centrifuging should certainly be performed at room temp. In the centrifuging a speed of 750 r. p. m. proved most satisfactory. With a simple lithopone flat wall paint a 4-day cycle consisting of 2 one-hr. centrifuging periods per day produced settling equiv. to 1 yr. of normal shelf storage. For a lithopone paint contg. 1% of a weak H<sub>2</sub>O soap soln. a 4-day cycle consisting of 2 half hr. centrifuging periods per day was satisfactory. H. Stoertz

**A study of the effect of addition agents on floating of pigments in paints and enamels.** Edwin Edelstein. *Am. Paint J.* 17, No. 53A, 11 *et seq.*; *Paint, Oil & Chem. Rev.* 95, No. 22, 40 *et seq.*; *Am. Paint & Varnish Mfrs'. Assoc. Circ.* No. 445, 481-97 (1933); cf. *C. A.* 26, 1130. It is postulated that exact neutralization by adsorption of suitable compds. will reduce floating. To det. the amt. of adsorption compd. necessary for neutralization, pigments were shaken with dil. petroleum spirits solns. of various materials, *e. g.*, rosin, stearic acid, NH<sub>4</sub> stearate, stearanilide, rosin anilide and the amt. of solute unadsorbed was detd. Various combinations of pigments and the above named materials were incorporated into paints and the behavior of the paints in an electrostatic field studied to det. the amt. of charge remaining on the pigment. The reduction of floating was not proportional to the reduction of the charge on the pigment. The effects of the addn. agent on gloss and drying were also detd. Illustrated. G. G. Sward

**Antimony oxide its properties and uses.** H. S. Riker. *Am. Paint J.* 17, No. 39, 47-52 (1933). —The general properties of Sb oxide pigment are described. Its unique properties are soft texture, low oil absorption and easy wettability. It imparts to paints good flow and slow drying and slow chalking properties. G. G. Sward

**A study of various pigments and vehicles in rust-inhibitive primers.** Pittsburgh Paint & Varnish Production Club. *Am. Paint J.* 17, No. 53B, 8 *et seq.*; *Am. Paint & Varnish Mfrs'. Assoc. Circ.* No. 445, 469-76 (1933). The rust-inhibitive values of single pigment paints were studied by means of (1) salt spray, (2) weatherometer, and (3) exterior exposure tests. The results are given in extensive tables. According to 1, Zn chromate and blue Pb; to 2, pptd. black Fe oxide; Pb chromate, Zn

chromate and red Fe oxide; and to 3, Pb chromate, Zn chromate and Al bronze appear best. G. G. S.

**Cadmium, thallium, indium and gallium as by-products of the lithopone industry.** W. N. Hirschel. *Chemistry and Industry* 1933, 797-8. E. H.

**Light fastness of coal tar color lakes.** Heinr. Haase. *Farbe u. Lack.* 1933, 484, 498. —Considerable confusion regarding light fastness of color lakes is due to non-uniformity of tests. Tests should always be made upon the finished paint. G. G. Sward

**New developments in driers.** C. A. Klebsattel. *Paint & Varnish Production Mgr.* 9, No. 11, 28-30 (1933). —Coincident with the development of synthetic resins, improved chem. pigments, petroleum solvents, etc., the naphthenate driers have appeared. Their superiority is due to uniformity, better soly., less after-staining and stability. G. G. Sward

**Drier standardization. The aridyne.** IV. W. Grier Armstrong. *Am. Paint J.* 17, No. 53B, 20-1; *Am. Paint & Varnish Mfrs'. Assoc. Circ.* No. 445, 498-505 (1933); cf. *C. A.* 26, 1140. —The relative drying times of oils are shown to be dependent upon the consens. of the driers, the natures of the oils and on atm. conditions. The aridyne, therefore, loses its chief virtue, *viz.*, stability. G. G. Sward

**Effect of driers on durability (of paint).** Cincinnati-Dayton-Indianapolis Paint & Varnish Production Club. *Am. Paint J.* 17, No. 53B, 11 *et seq.*; *Am. Paint & Varnish Mfrs'. Assoc. Circ.* No. 445, 508-20; *Paint, Oil & Chem. Rev.* 95, No. 22, 74-7, 100 (1933). —After 26 weeks of exterior exposure of the varnishes described in *C. A.* 27, 613, the following conclusions were reached. Pb in amts. up to 1.5% and Mn up to 0.4% did not reduce the durability. On the other hand, durability was inversely proportional to the amt. of Co in the varnish. Driers tend to increase tensile strength, reduce elongation and the resistance to exposure in a Fade-O-meter, in which aged films showed better durability than fresh ones. Co produced the hardest films, Pb the softest. There was no difference in durability due to the use of linoleate or naphthenate driers. G. G. Sward

**Rational syntheses in the field of drying oils.** Johannes Scheiber. *Angew. Chem.* 46, 643-7 (1933). —The synthesis of products, which are characterized by conjugated-unsatd. groups, is discussed, and drying curves as well as graphs showing I nos. and coagulation capacities as functions of heating time are presented. Twelve references. Karl Kammermeyer

**Oil absorption and space filling.** Hans Wolff and G. Zudler. *Farben-Ztg.* 38, 1495-7 (1933). —A statistical study of over 100 cases of oil absorption data shows that the ratios (vol. pigment at crit. oil content)/(vol. pigment at min. oil content) fall into 4 groups. The assumption that the particles of a paint are in cubic arrangement at the crit. oil content concn. (*C. A.* 26, 1456) must be extended to include the 4 groups which may or may not include other arrangements. It is therefore impossible to calc. the crit. oil content from detns. of min. oil content (cf. *C. A.* 27, 3348). G. G. Sward

**Further experiments on the importance of the critical point.** Hans Wolff. *Paint & Varnish Production Mgr.* 9, No. 10, 5 *et seq.*; No. 11, 16 *et seq.* (1933); cf. *C. A.* 26, 1161. Addnl. evidence for the existence of the crit. oil content is given. Brushability has a relation to the crit. oil content only in paints made with raw linseed oil. However, other properties, such as tensile strength, resistance to liquids, etc., do depend upon the oil content of paints made with stand oil. Bodying of stand oils takes place in 3 stages: (1) in which linolic acid is converted to a high-melting isomer with 1 inactive double bond and linolenic acid no longer gives hexabromides; (2) in which the I no. of linolenic acid is reduced; and (3) in which greater changes in  $\eta$  but only lesser ones in I no. occur. The evidence is based upon isolation from (1) of high-melting acids of high refractive index with relatively low mol. wts. and Br values (Becker-Rossmann). G. G. S.

**Polymerization of linseed oil.** H. I. Waterman and

D. Oosterhof. *Rac. trav. chim.* 52, 895-900 (1933).—High-vacuum distn. app. is described in which a thin film of the liquid is in contact only 8-4 sec. with the heated surface, both distillate and residue being cooled immediately afterward. By use of a vacuum obtained by immersing charcoal in liquid air, linseed oil could be almost completely distd. without significant change in const. Stand oil (viscosity 55 poises) gave 19 g. of distillate having poor drying properties, becoming cloudy on standing, and consisting of unpolymerized glycerides (mol. wt. 757) and 41 g. of nondistillable residue (mol. wt. 3468, viscosity 379 poises) which remained clear on standing, dried better than the original stand oil, and had a lower acid no. The 2 fractions had nearly the same I no. and ultimate analysis. Arnold M. Collins

Water absorption by varnish and lacquer coats and its relation to their composition. P. W. Serb-Serbin, *Malyarnoe Delo*. 1931, No. 5/6, 62-75; *Chem. Zentr.* 1932, 1, 2388.—Varnishes having exclusively liquid film formers or binders (linseed and wood oils) show the greatest H<sub>2</sub>O absorption. The largest value is shown by oxidized oils (30%), 23.6% is shown by polymerized oils, and a max. of 15% by polymerized-oxidized oils. Addn. of wood oil to linseed decreases the H<sub>2</sub>O absorption. Russian and Chinese wood oils being quite different in this respect. Introduction of solid binders (resin esters) retards H<sub>2</sub>O absorption, so that twice the time is required to reach the same max. absorption, but otherwise improves H<sub>2</sub>O absorption and resistance of the films. Increasing the resin ester and decreasing the oil content almost doubles the hardness of the film. Introduction of nitrocellulose and decreasing the oil content decrease the quantity of H<sub>2</sub>O absorbed, the film finally reaching a stable condition with 12.8% H<sub>2</sub>O absorbed. Red ochre has no effect on the H<sub>2</sub>O absorption of varnishes having liquid binders (with the exception of polymerized oils); it decreases the adhesion about 23%. The same holds for varnishes with solid and liquid binders. Chrome orange greatly retards H<sub>2</sub>O absorption and increases the adhesion (liquid binders) about 25%. Pigmented heavy oil from Chinese wood oil is an exception. PbCrO<sub>4</sub> improves varnishes with solid and liquid binders without increasing their adhesion. M. G. Moore

Mat varnishes. Kern *Farbe u. Lack* 1933, 511 15. Hints for selection of matting media for varnish and lacquer are given. G. G. Sward

Baking varnishes for the metal-decorating industry. Fritz Zimmer *Farben Ztg.* 38, 1530 1 (1933).—A few properties of baking enamels for tin plate, and machinery for application and baking of the enamels are given. G. G. Sward

Shellac production in India. K. De Basanto *Farbenchem.* 4, 293 6, 325 7, 412 15 (1933). G. G. Sward

Clarifying and straining of surface coatings. Wm. DeCamp and J. McF. Sanders *Am. Paint J.* 17, No. 53A, 24 5, *Am. Paint & Varnish Mfrs.' Assoc.* (circ. No. 445, 438 42; *Paint, Oil & Chem. Rev.* 95, No. 12, 78 9 (1933)). G. G. Sward

An experiment in the temperature effect of various colored coatings on contents of tanks. Lloyd R. Moses. *Paint, Oil & Chem. Rev.* 95, No. 20, 9 10 (1933).—White enamel, Al paint and black paint ranked in the order named in their effectiveness in reflecting the heat of the sun from 55 gal. drums contg. H<sub>2</sub>O and 1 gal. cans contg. mineral spirits. G. G. Sward

Efflorescence on black enamels. Felix Fritz. *Farbe u. Lack* 1933, 475.—A case of white efflorescence on black enamel was diagnosed as sweating of fatty acids of high m. p. G. G. Sward

The behavior of aluminum stearate with various solvents. Francis J. Licata. *Official Digest, Fed. Paint & Varnish Production Clubs* No. 129, 250-60 (1933); cf. *A.* 27, 4105.—Hydrocarbons are more effective dispersing agents than esters, alcs., ketones, etc. Aromatic hydrocarbons are more effective than aliphatic, and long chain more effective than short chains. For flattening purposes the dispersions should be kept cool during

grinding, as gelling and loss of flattening properties is induced by high temps. G. G. Sward

Aqueous emulsions of cellulose ester solutions. Walter König. *Farbe u. Lack* 1933, 461-2, 474-5.—Emulsifiability of nitrocellulose solns. was detd. by adding H<sub>2</sub>O drop by drop to 12.5 or 25 g. with vigorous stirring until an excess of 2.5 cc. was obtained. The emulsion no. passed through a max. as the viscosity of the nitrocellulose soln. increased. Plasticizers may increase or decrease the no. All films laid down from emulsions dried white. Water-sol. solvents must not be present. G. G. Sward

Non-metal constituents in bright gold. II. Akira Nakatsuchi. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 524 5 (1933); cf. *C. A.* 27, 3625.—The influence of impurities such as organo-halogen compds. and organo-S compds. on bright gold was studied and the course of change during the heating of balsam golds and rhodium balsam was investigated. Karl Kammermeyer

Dope poisoning as a potential hazard in spray-coating airplane wings. Clifton A. Young. *U. S. Naval Med. Bull.* 31, (38-86) (1933).—It is recommended that benzene, tetrachloroethane and o-trichlorophosphate be excluded from a standard formula for navy airplane dopes. B. C. Brunstetter

Chlorinated resins. C. A. Redfern *Paint Manuf.* 3, 312 14 (1933).—A brief review. G. G. Sward

Plant equipment from synthetic resins. D. H. Killefer. *Ind. Eng. Chem.* 25, 1217-19 (1933).—The development of liquid molding compds. which contain asbestos fiber and Ph(OH-CH<sub>2</sub>O) resin and which may be hardened without pressure allows the manuf. of large and intricate shapes without expensive molding equipment. Absence of cellulosic fillers makes the product highly acid resistant without loss of strength. It may be drilled, threaded, etc., like wood and may be satisfactorily joined by autogenously hardened cement. Arnold M. Collins

Cannabis indica resin (Cahn) 10. Lacquers for the canning industry (Barry) 12. Azo dyes [for coloring lacquers] (Ger. pat. 583,224) 25. App. for polishing colored pulverulent bronze (U. S. pat. 1,930,683-4) 9.

Gardner, Henry A.: Physical and Chemical Examination of Paints, Varnishes, Lacquers and Colors. 6th ed. Washington. Inst. of Paint & Varnish Research. 1500 pp. \$11.00. Reviewed in *Ind. Eng. Chem.* 25, 1406 (1933).

Paints, varnishes, etc. 1. G. Farberund A.-G. Fr. 749,156, July 20, 1933. Products serving as a basis for paints, etc., are made by polymerizing transformation products of vegetable oils which are at least partially drying, in common with polymerizable ethers and ketones which contain at least one vinyl radical. The transformation products are obtained by esterification of the oils by means of alcs. other than glycerol, or by heating the oils in the presence or absence of air, if necessary in the presence of polymerization catalysts. Fr. 749,157. The ethers or ketones are replaced by a polymerizable open chain aliphatic hydrocarbon contg. at least one vinyl radical. Fr. 749,158. The ethers or ketones are replaced by a polymerizable vinyl compd. of the formula RX (R is an alkyl radical contg. a vinyl group and X is halogen or CN).

Paints and varnishes. George H. Potts. Brit. 393,045, June 7, 1933. Anticorrosive varnishes, which may be mixed with pigments to give paints, contain a paste boiled oil obtained by adding to boiling flaxed oil a soln. of mastic in turpentine, white lead, Zn white, shellac varnish, borax and AcOH and, after cooling, adding copal varnish and turpentine. The oil is mixed with (1) raw flaxed oil, copal or other varnish free from colophony, a paste consisting of Zn white, white lead, linseed oil and copal varnish and a soapy liquid consisting of alum, soda, olive oil, turpentine, coconut oil, palm oil and lard and (2) in addn. to the ingredients of (1) a varnish consisting of

shellac, methylated spirit, venice turpentine and Am-OAc, together with small proportions of vegetable oils, *e. g.*, coconut, palm or olive.

**Pigments.** Carl J. Harbert (to the Harshaw Chemical Co.). Brit. 393,474, June 8, 1933. Pigments are obtained by heating together O-contg. compds. of Ti, Sb and Cr in the presence of an element that is electropos. to the other 3 constituents at high temp., *i. e.*, combines as a base therewith. The products are insol. in  $H_2O$ , acids and alkalis, inert to most chem. reagents at high temp. have high opacity and covering power, range from light yellow through orange and brown to olive and may be used in the manuf. of pottery, paints, cements and rubber articles. Among examples mixts. of (1)  $TiO_2$ ,  $Sb_2O_3$ ,  $CrO_3$  and  $NaOH$  and (2)  $MgCO_3$ ,  $SuO_2$ ,  $SrCO_3$ ,  $CdO$ ,  $NiCO_3$ ,  $Al_2O_3$ , Na silicate, kaolin or feldspar,  $TiO_2$ ,  $CrO_3$  and  $Sb_2O_3$  are heated.

**Drying extract.** I. G. Farbenind. A.-G. (Friedrich Meidert and Hermann Schutz, inventors). Ger. 576,939, May 19, 1933. A homogeneous drying ext. readily sol. in drying oils and volatile org. solvents is prepd. from heavy or alk. earth metal salts of naphthenic acids and fatty acid drying or semi-drying oils such as linseed, wood, soy-bean or poppy seed oils. The product is used in the paint and varnish industry. In an example, naphthenic acid is saponif. with  $NaOH$  and the clear soln. treated with  $Co_2(SO_4)_3$ . The resulting ppt. is washed and mixed with linseed oil.

**Modified vegetable oils.** Institut für Lackforschung (G. m. b. H. (Felix Wilborn and Erdmann Rieger, inventors). Ger. 583,249, Sept. 9, 1933. Vegetable oils such as linseed oil are thickened by heating for several hrs. to  $240^\circ$  or more after addn. of a small proportion of an oil-sol. compd. of Th, *e. g.*, Th resinate, lincolate, naphthenate or stearate.

**Varnishes.** Elektrochemische Werke München A. G. Brit. 395,299, July 13, 1933. A varnish comprises a colloidal aq. soln. of wood oil stand oil, *e. g.*, wood oil stand oil 75, Co resinate 2 and turpentine oil 25 parts may be mechanically dispersed in 100 parts  $H_2O$  to which 1 part of an emulsifying agent, *e. g.*, K resinate, has been added.

**Lacquers.** Aug. Nowack A.-G. and Richard Hessen. Fr. 750,574, Aug. 12, 1933. In making lacquers contg. artificial resins, particularly  $PhOH-CH_2O$  resins, the filling and coloring materials are incorporated in the resins by kneading under pressure and at a temp. at which the resin becomes plastic or liquid, before adding the usual solvents.

**Colored lacquers and plastic masses.** Soc. pour l'ind. chim. à Bâle. Ger. 584,387, Oct. 11, 1933. See Brit. 385,409 (C. A. 27, 4429).

**Nitrocellulose "dope" for coating airplane and balloon fabrics, etc.** Linton C. Amberson. U. S. 1,931,368, Oct. 17. A soln. of nitrocellulose is treated with an aq. soln. of a Zn salt such as  $ZnCl_2$  and  $HCl$  to effect pptn. of the nitrocellulose; the acid liquor is then drawn off, the residue is washed with an aq. soln. of a Mg salt such as  $MgSO_4$  and finally washed with water; a plasticizer is added to the wet residue and it is worked with further sept. of water, and dissolved in a liquid contg. volatile solvents.

**Japanned metallic tiles.** Sotojiro Asobe. U. S. 1,930,990, Oct. 17. The surface of tiles such as those formed of Al or Mg alloys is coated with a moist mixt. of red ochre, tonoko (lignified fine powder of clay slate or fine powder of Japanese grinding stone) and kirurushi (raw japan); the coated material is heated to  $180-220^\circ$  and the surface is polished, treated with a coat of japan and again polished.

**Printing composition suitable for use on wet lumber.** Logan A. Mizener (to Chicago Mill and Lumber Corp.). U. S. 1,930,178, Oct. 10. A pasty base of starch and water is used with a water-sol. aniline color, glycerol and vinegar in specified proportions.

**Printing on sausage casings or other articles of regenerated cellulose.** Julius Voss (to Visking Corp.). U. S. 1,929,394, Oct. 3. In order to fix them, imprints which may be formed with an oil-base ink on regenerated

cellulose articles are dried and then subjected to a high temp. (suitably about  $100^\circ$ ) in a relatively humid atm.

**Rosin composition resistant to crystallization.** Irwin W. Humphrey (to Hercules Powder Co.). U. S. 1,931,226, Oct. 17. Rosin is mixed with about 15% or less of a rosin-distn. residue, in order to form a product which is suitable for use in core oils, varnishes, printing inks, etc.

**Apparatus for making molded inlaid linoleum.** Edward J. Kessler (to Armstrong Cork Co.). Brit. 396,047, July 25, 1933.

**Synthetic resins.** E. I. du Pont de Nemours & Co., Walter E. Lawson and Lloyd T. Sandborn. Brit. 392,924, May 15, 1933. Vinyl compds., *e. g.*, vinyl acetate, chloride or styrene, are polymerized in the presence of non-polymerized, non-oxidized drying oils in the absence of  $H_2O$ . Among examples (1) vinyl chloride and raw linseed oil are polymerized in the presence of Bz peroxide, (2) styrene and alkali-refined linseed oil are polymerized in soln. in ethylbenzene and (3) a spraying enamel consists of the resin of example (2), dioxylethane, a drier and "Titanox" pigment dissolved in a mixt. of  $C_6H_6$ , PhMe and xylene. Cf. C. A. 27, 3837.

**Synthetic resins.** Walter W. Durant and Paul H. Scrutcheild (to The British Thomson-Houston Co. Ltd.). Brit. 393,034, June 1, 1933. A dihydric alc., *e. g.*, propylene, diethylene or tetramethylene glycol, an alc. having 3 or more OH groups in the mol., *e. g.*, glycerol, a dibasic aliphatic acid, *e. g.*, malic, maleic, fumaric, glutaric, adipic, pimelic or suberic, a polybasic acid other than a dibasic aliphatic acid, *e. g.*, phthalic, citric or tartaric, a vegetable oil, *e. g.*, linseed, perilla or soy-bean, and a natural resin, *e. g.*, dammar, kauri or copal, or resinic acid derived therefrom, are condensed together to give a resinous compn. Cf. C. A. 27, 4431.

**Synthetic resins.** I. G. Farbenind. A.-G. Ger. 576,714, May 16, 1933. Resinous condensation products are produced by condensing polyhydric alcs. partly esterified by fatty acids, with phenols and treating the product with  $CH_2O$ . Alternatively, the polyhydric alc. can be condensed with a phenol, then partly esterified by a fatty acid, and finally treated with  $CH_2O$ . In an example, the mono ester of glycerol and lauric acid is condensed with  $PhOH$  in the presence of  $ZnCl_2$ , and treated with  $(CH_2O)_2$  to give a mass useful in the lacquer industry.

**Synthetic resins.** Allgemeine Elektrizitäts-Ges. Ger. 582,164, Sept. 2, 1933. In the manuf. of resins from polyhydric alcs. and polybasic acids or their anhydrides, *e. g.*, from glycerol and phthalic anhydride, an amino-carboxylic acid is added at any stage before the conversion of the resin into its final form. The amino acid may be formed *in situ*, *e. g.*, from  $PhNH_2$  and  $ClCH_2COOH$ . Preferably, 0.25-0.75 mol. of amino compd. is taken per mol. of polyhydric alc. Blue resins of improved mech. and elec. properties are obtained. The color may be changed by after-treatment, *e. g.*, with Br. Examples are given.

**Casting synthetic resins.** Ambi-Verwaltung A.-G. (Arthur Muller, Stefan Goldschmidt, Emil Gerisch and Wilhelm Beuschel, inventors). Ger. 584,308, Sept. 19, 1933. Details are given of a method of mfg. large disks from synthetic resins of the urea- $CH_2O$  type. The principal features of the method are (1) the use of closed vertical molds made of acid material, *e. g.*, an acid glass, and (2) the drying of the molded disks in an air stream of gradually rising temp. and a humidity about 10-40% below the satn. pressure of water vapor at the obtaining temp.

**Artificial resin compositions.** James G. F. Wright (to The British Thomson-Houston Co. Ltd.). Brit. 394,450, June 29, 1933. Alkyd resins, modified or not with vegetable oils or their fatty acids, in a state no longer permitting soln. in a volatile solvent but still capable of absorbing such solvent accompanied by swelling (the B-stage) are treated with a swelling agent, *e. g.*,  $Me_2CO$ ,  $Me$  cellosolve or mixts. of  $C_6H_6$  and alc., in the presence of a plasticizer, *e. g.*, vinyl chloride or acetate, tricresyl or diphenyl phosphate, camphor, dibutyl phthalate and the

product, with or without fillers and (or) pigments is molded. The alkyd resin may contain its own plasticizer in the form of an ester of the ingredients used, e. g., glycol succinate or adipate. Examples are given. Cf. C. A. 27, 5906.

**Artificial resin molding compositions.** Imperial Chemical Industries Ltd. and Wm. J. S. Naunton. Brit. 395,023, July 10, 1933. Comps. for making articles having variegated color surfaces are made by placing layers of colored molding powders, comprising phenol-aldehyde condensation products in the A stage, fillers and pigments, in a container, heating to about 100°, extruding and, if desired, breaking the extruded mass into fragments. In an example brown molding powder is placed in a vertical cylindrical extrusion press, provided with a hole near the

bottom at 1 side, red powder is poured over it and the mass is heated and extruded to produce rods colored red and brown.

**Molding artificial resin.** Frazier Groff (to Carbide & Carbon Chemicals Corp.). Brit. 392,770, May 25, 1933. To produce composite molded articles comprising a metallic portion and a portion of polymerized products of vinyl compds. with or without fillers, e. g., cellulose, alk. earth, metal salts of fatty acids, or natural or artificial acid resins, and also with or without fluxing agents, e. g., curcumba wax, the metallic portion is treated by etching, plating or sizing with a priming agent to cause the vinyl compd. to adhere on the application of heat and pressure. Suitable sizing materials are  $\beta$ -coumarone resin and resins of the Glyptal group.

## 27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

**The detection of the adulteration of cacao butter. Determination of the azelaic acid number.** G. Schuster. *Compt. rend.* 197, 760 2(1933); cf. C. A. 27, 1955.—The azelaic acid no. is defined as the no. of mg. KOH required to neutralize the acidity of 1 g. of the mixed insol. acid glycerides obtained by  $\text{KMnO}_4$  oxidation of the fat. Direct detn. of this const. by sepn. of the glycerides and acidimetric titration is a delicate operation on account of the difficulty of eliminating pelargonic acid which is but slightly sol. in  $\text{H}_2\text{O}$ . The following technique, which makes use of the considerable difference in soly. of the Mg salts of pelargonic acid and of azelaic esters in 80% alc., is recommended: Oxidize 40 g. cacao butter dissolved in 400 cc.  $\text{Me}_2\text{CO}$  with 160 g.  $\text{KMnO}_4$ ; dissolve the mixed acids in 350 cc. 80% alc.; to the hot soln. (70–80°) add a hot soln. of 6 g. anhyd.  $\text{MgCl}_2$  in 60 cc. 80% alc.; let stand 24 hrs. at 15°, filter, wash with 100 cc. 95% alc. and then with distd. water, dry in vacuum over  $\text{H}_2\text{SO}_4$ ; in 1 g. of the Mg salts det. Mg as  $\text{MgSO}_4$  and calc. therefrom the equiv. KOH. Cacao butter has an azelaic acid no. of 98.7; Karite butter, 131.1. In mixts. of the 2, the compn. can be calcd. from the azelaic acid no.; in more complex mixts., it can detect adulteration.

**A. Papineau-Couture**  
**Report on (the analysis of) fats and oils.** Geo. S. Jamieson. *J. Assoc. Official Agr. Chem.* 16, 568–9(1933); cf. C. A. 27, 2001.—Detn. of the acidity and sapon. no. of extd. cottonseed oil gives higher results by the Albert method than by the present official A. O. A. C. method.

**A. Papineau-Couture**  
**The fat and the oil from the seeds of Actinodaphne hookeri Meissn. An indigenous source of lauric acid.** S. V. Puntambekar and S. Krishna. *J. Indian Chem. Soc.* 10, 395 100(1933).—Ninety-six % of the fat which was extd. from the kernel of the seeds was shown to be trilaurin. The remainder was chiefly triolein. Some trilaurin was obtained from the seed shells. The oil remaining after sapon. was a small amt. of resin acids, a mixt. of glycerides of oleic acid and isomeric oleic acids. P. and K. suggest the use of the fat as a convenient source of lauric acid.

**Julius White**  
**New method for the capillary fractionation of fatty acids.** René Dubrisay. *Chimie et industrie Special No.*, 1045–7(June, 1933).—Gibbs' principle that the compn. of the surface film of a soln. has not the same compn. as the mass of the liquid is generalized, showing that the impoverishment or enrichment of the surface film varies with different solutes. Application of this principle is made to the sepn. of 2 or more soaps in a given soln.; by bubbling air through the soln. and sepr. the foam considerable sepn. may be effected. Several examples are given.

**A. Papineau-Couture**  
**Chemical constitution of the unsaturated fatty acid  $\text{C}_{20}\text{H}_{38}\text{O}_2$  in Japanese sardine oil.** Masakichi Takano. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 550 1 (1933).—The mixed fatty acids were sepd. by the Na and Pb salts-acetone method and fractionated as Me esters.

From the 220–5° fraction (at 6 mm.) the fatty acids were liberated, converted to the Li salts and fractionally sepd. by means of alc. Nearly pure eicosenoic acid was obtained which had a neutralization value of 180.28, and an I no. of 82.34 and m. 22–23°. Its chem. constitution was ascertained to be  $\text{CH}_3(\text{CH}_2)_9\text{CH}=\text{CH}(\text{CH}_2)_7\text{COOH}$ .

Karl Kammermeyer

**Unsaturated fatty acids of the oleic series in Japanese sardine oil.** Masakichi Takano. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 549–50(1933).—The mixed fatty acids from the sapon. of oil were sepd. by the Na and Pb salts-acetone methods. The liquid fatty acids were converted into their Me esters and fractionated by vacuum distn. The acids identified were (1) zoömaric acid, (2) oleic acid (probably normal), (3) gadoleic acid, and (4) eicoteic acid. Acids (1) and (2) constitute 20–30% of the total mixed fatty acids. Five references. K. K.

**Examination of the fatty acids separated from soaps.** G. Wolff. *Chimie et industrie Special No.*, 1039–42 (June, 1933).—Attention is drawn to the complexity of the problem of detg. the nature and amts. of fats used in the manuf. of soaps made from several different fats. Emphasis is laid on the value of the titer test, the value of which, however, is not proportional to those of the materials used. Curves are given showing the variation in the titer test of various mixts. of peanut, coprah, tallow, stearic acid, palm oil, horse fat, soy-bean oil, linseed oil and rosin.

A. Papineau-Couture

**Taffel and Revis method for estimating the rancidity of oils and fats.** J. K. Giles. *Chemistry and Industry* 1933, 816 17.—The method of T. and R. (C. A. 25, 2315) is revised as follows: Through a 2-oz. bottle contg. 40 ml. of glacial  $\text{AcOH}$  kept in  $\text{H}_2\text{O}$  at 95–100°, pass a stream of  $\text{CO}_2$  for 2 min. Next add 2 ml. of 50%  $\text{KI}$  with the  $\text{CO}_2$  still on, and after 1 min. pour in a weighed amt. of liquid fat (approx. 10 ml.) and obtain the wt. by reweighing the cylinder. Pass the  $\text{CO}_2$  for 4 min. and then pour the bottle contents into 150 ml. of  $\text{H}_2\text{O}$  and titrate with 0.02  $N$   $\text{Na}_2\text{S}_2\text{O}_3$  with starch soln. as indicator. Make a blank detn.

E. Scherubel

**Determination of the hydroxyl number.** W. Normann and F. Schilcknecht. *Fettchem. Umschau* 40, 194–7(1933).

The following modification of the Verley-Rölsing method for acetyl no. has been developed by N. and S.: Into a 150-cc flask weigh enough substance to use up only  $\frac{1}{2}$  of the  $\text{Ac}_2\text{O}$  to be added, and from a pipet weigh 4 cc. of a fresh mixt. of 1 vol.  $\text{Ac}_2\text{O}$  and 2 vols. pyridine. Cover the flask with a funnel and immerse it 1 cm. for 1 hr. in boiling  $\text{H}_2\text{O}$ . Cool, rinse the funnel with 0.5–1.0 cc.  $\text{H}_2\text{O}$ ; cool again if heat is liberated, dil with neutral alc. and titrate back with 0.5  $N$  alc. KOH and phenolphthalein; run a blank. Then: hydroxyl no. =  $[(b - a)28.055/e] + A$ , where  $a$  = cc. 0.5  $N$  KOH,  $b$  = cc. used in blank,  $e$  = wt. of substance and  $A$  = any free acid no. the substance may have had. There is also described a method for the detn. of alcs. whose esters are volatile in mixts. of fatty acids and neutral fats. P. E.

The oil production from sunflowers and its economic significance for Germany. K. Riccius. *Fellchem. Umschau* 40, 201-4 (1933).—A plea for introducing sunflower cultivation in Germany. P. Escher

Russian soy-bean oil. S. Yushkevich. *Fellchem. Umschau* 40, 197-200 (1933).—An extensive table shows the const. and compns. of 13 carefully prep'd. soy-bean oils from all parts of the Soviet Union, mostly of the Kruschula type of soy-bean between 41° and 53° N. Latitude and from 36° to 132° E. Longitude. The oils show a fairly const. linoleic acid content of 50%, but the northern country produces oils with a greater percentage of linolenic and a lesser percentage of oleic acid, while southern latitudes produce oil with small amts. of linolenic acid and larger amts. of oleic acid. In general the const. agree with published values, except that some of the northern samples exceed the values for I no., hexabromide no. and thiocyanate no. Limits are: sat'd acids 11.22-20.55, oleic acid 18.33-32.62, linoleic acid 41.90-56.27, linolenic acid ( $\alpha$ - $\beta$ ) 0.46-12.49,  $\alpha$ -linolenic acid 0.0-3.71%. P. Escher

A system of control for oil-palm factories. C. D. V. Georgi. *Malayan Agr. J.* 21, 113-25 (1933). E. H.

Oil from the seeds of *Tectona grandis* (Teak). S. V. Puntambekar and S. Krishna. *J. Indian Chem. Soc.* 10, 401-3 (1933). The extr. of 50 g. of kernels with ether produced 20.45 g. of a bright red oil. No essential oil could be obtained by steam distn. Sapon. and removal of the non-saponif. fraction produced chiefly stearic and palmitic acids, while the liquid acids were mainly oleic and linoleic. P. and K. believe the insecticidal properties are due to the resin acids only. Julius White

The composition of oil of *Jatropha curcas* L. (Barbadoes nut). M. Th. François and S. Drott. *Bull. soc. chim.* 53, 728-11 (1933). Analysis of 2 com. samples and 5 samples prep'd. in the lab. by extr. with petr. ether (boiling below 60°) of seeds of different origin, showed the following characteristics:  $d_4^{20}$  0.9108-0.9205,  $n_D^{20}$  1.4720-1.4733, viscosity at 35° 0.277-0.375, viscosity at 100° 0.0568-0.077, f. p. -15° to -13°, calorific value 9,168-9,480 cal. per g., acid no. (of com. samples) 4.2-5.5, acidity (of lab. prep'd. samples) as percentage of oleic acid 0.4-0.6, sapon. no. 176-190, I no. (Hanus) 93-98, Ac no. (André) 4-9.6. The oil contains 80.5% total fatty acids having: neutralization no. 198, mean mol. wt. 283, sapon. no. 198, I no. (Hanus) 102, Ac no. (André) 0; the sat'd acids consist of stearic, palmitic and myristic acids; the unsat'd acids consist of approx. 78% oleic and 22% linoleic; the absence of hydroxy-acids is proved. The oil also contains about 0.1% of a resin-sterolic complex. A. Papineau-Couture

Ketiau oil from the seeds of *Ganua* (Bassia) motleyana (Sapotaceae). J. Zimmerman. *Chem. Werkblad* 30, 657-8 (1933).—From the seeds of *Ganua motleyana* the natives (Sumatra, Bangka, Borneo) press an oil used for baking and drying. From new and old seeds the oil has been extrd. with EtO for detn. of various const. The IICN content of oil from the fresh seed is higher than that from old seed. Both oils contain BzH. The cryst. part of the unsaponifiable matter consists of lupcol. The remainder of the unsaponifiable matter is a gutta-percha-like material. The fatty acids consist of stearic acid 18.56, palmitic acid 10.17, oleic acid 68.77 and linoleic acid 2.49% with very small amts. of lower acids. E. S.

A primary tar derived from exhausted olive oil mash. A. Mangini and F. Lablart. *Ann. chim. applicata* 23, 373-91 (1933); cf. *C. A.* 26, 1676. The tarry residue obtained from expressed olive-oil mash is extrd. with EtOH, acid, and basic solvents. Thus 5.80% of bases, 10.86% acids (both non-resinous and sol. in EtO), 30.25% phenols, and 23.53% neutral oils were recovered. Five alkylquinolines and 2 hydrogenated alkylquinolines were identified in the acid fraction, as well as formic acid,  $C_8H_{16}O_2$ , and octadecanocarboxylic acid. Five paraffins from  $C_{25}$  to  $C_{35}$  were identified in the neutral fraction, while the phenols are probably like pyrocatechol in compn. A. W. Courtieri

Portuguese (bees) waxes. \* Charles Lepierre and Abel de Carvalho. *Chimie & industrie Special No.*, 1087-93 (June, 1933).—The present status of the bees wax industry in Portugal and in its colonies is outlined. From the results of a large no. of analyses, which are tabulated, the following are suggested as criteria for yellow continental waxes, white continental waxes and yellow African waxes, resp.: acidity (in mg.) 19-19.5, 19.5; esters (in mg.) 72.5, 73, 73; sapon. no. 91.5, 92.5, 92.5; I no. (Wijs) 10.5-11, 6, 12-12.5; Hübl's ratio (combined acids/free acids) 3.85, 3.75, 3.75. A. Papineau-Couture

The composition of various recent washing compounds. C. Grunne. *Seifensieder-Ztg.* 60, 771-2 (1933).—The compns. of Persil, Ozonil, Clasen's Rapol, Beral, Pergolin, Bleichin and Standard washing compds. are given. Their dry soap content varies between 23.5 and 29.1%. P. E.

Washing powders containing perborates. R. Krings. *Seifensieder-Ztg.* 60, 751-5, 772-3 (1933).—A description of their mfg. process. P. Escher

Detergency of alkaline salt solutions. IV. Laboratory comparison in simulation of laundry practice. Foster D. Snell. *Ind. Eng. Chem.* 25, 1240-6 (1933); cf. *C. A.* 27, 1531. Exptl. washing by a modified Rhodes and Baird procedure gives reproducible results in the same lab. A soap builder alone is primarily a detergent only to the extent that it can react with free fatty acid in the soil to produce soap. Secondly it may be effective because of improved wetting power of the detergent soln. One of the important functions of a soap builder is to speed up detergency. This may be expressed as a measure of the rate of removal of soil. Based on several factors, the order of decreasing value as detergents of the builders studied is:  $Na_4SiO_4$ ,  $Na_2SiO_3$ , a mixt. of  $Na_2SiO_3$  and  $Na_2CO_3$ ,  $NaOH$ , modified soda and  $Na_2CO_3$ . The behavior of colloidal soap builders is clearly distinguishable from that of noncolloidal soap builders. Acidity of dirt increase the ease with which it is removed. The theory is advanced that the efficiency of the different builders with soap is some pos. power of the no. of units of brightness regained in washing. It is estd. as not less than the second, or greater than the third power. The data are in agreement with the micelle theory of detergency. F. D. S.

Czechoslovakian hop oil and its utilization [in the soap industry] (Nehovidské, Horel) 16. Aq. dispersions such as those of oils, fats and fatty acids (U. S. pat. 1,930,845) 13. Prepp. barbourite for oil treatment (U. S. pat. 1,930,572) 4.

Fischer, Emil J.: Wachse wachssähnliche Stoffe und technische Wachsgebinde Dresden: T. Steinkopff. 192 pp. About 12 M., bound about M. 13.20.

Rendering fat from fat-containing tissue. Halvor O. Halvorsen, Edward M. Schmitz and Robert C. Murray (to Geo. A. Hormel & Co.). U. S. 1,930,169, Oct. 10. The material is treated (suitably by macerating and adding NaCl) to increase its elec. cond.; an elec. current is then passed through the mass to heat the tissue to a fat-rendering temp., and the rendered fat is permitted to drain from the tissue. App. is described.

Apparatus for rendering fats. Darling & Co. Ger. 584,478, Sept. 20, 1933. This corresponds to Brit. 374,438 (*C. A.* 27, 4113).

Drying oleaginous seeds and fruits. Hermanus J. Hutteman. U. S. 1,929,691, Oct. 10. Materials to be dried such as copra or the like are submerged (preferably after being comminuted) in heated oil such as coconut oil in a vacuum and at a temp. above the b. p. of water at the vacuum pressure used. App. is described.

Casting soap. Baker Perkins Ltd., Edwin T. Webb and Anciens établissements A. Savy, Jeanjean et Cie. Brit. 394,365, June 26, 1933. In molding soap by an endless chain of molds traveling under filling means and through a cooling chamber the molds are preheated approx. to the temp. of the liquid soap and preferably are formed

with 4 hinged sides opening out to release the molded cakes, and the cooling is effected gradually and progressively to prevent sudden chilling of the cakes. The filling may take place in a vacuum chamber. App. is described.

**Disinfectant soaps.** Deutsche Gold- und Silber-Scheideanstalt vormals Roessler. Brit. 395,570, July 20, 1933. See Fr. 746,401 (C. A. 27, 4707). In 395,572, July 20, 1933, addn. to 395,570, a Ag compd. that is neither insol. nor readily sol. in  $H_2O$ , e. g., Ag subchloride, subbromide and thiocyanate, is incorporated in soap. Metallic Ag,  $NaBO_3$ , Na pyrophosphate peroxide, etc., may be added also.

**Condensation products from benzoin.** Soc. pour l'ind. chim. à Bâle. Ger. 582,380, Aug. 14, 1933. Addn. to 517,498 (C. A. 25, 2575). Products useful as wetting and emulsifying agents are obtained by treating naphthalenesulfonic acids with benzoin and an aliphatic or cyclic alc., together or in either order, in the presence of a condensing agent, e. g.,  $H_2SO_4$  or  $HSO_3Cl$ . Alternatively, a mixt. of  $C_{10}H_8$ , benzoin, and an alc. may be treated with a reagent having both a sulfonating and a condensing action. Examples are given.

**Detergents, etc.** René Meunier. Brit. 394,843, July 6, 1933. Products for use in degreasing, deozing, goffing and dressing textiles and in bleaching, dyeing and mercerizing baths are obtained by sulfonating a mixt. of fatty substance and solvents therefore and sapon. with alc. caustic alkali at preferably below  $70^\circ$ . The products may be added to soaps. The sulfonated mixt. may be neutralized with soda or  $NH_3$  before sapon. Solvents specified are  $C_8H_{18}$ , turpentines,  $Me_2CO$ ,  $AmOAc$  and those contg. Cl.

**Wetting agents, etc.** Imperial Chemical Industries Ltd., Anthony J. Hailwood and Wm. Todd. Brit. 393,276, May 25, 1933. Emulsions and dispersions of mineral and vegetable oils, fats, tar oils and other  $H_2O$ -insol. liquids and waxes are obtained by using as an emulsifying agent a quaternary  $NH_4$  salt contg. 1 alkyl or alkylene radical the chain of which contains not less than 10 C atoms but no alc. OH groups, e. g., dodecyl, cetyl or octadecyl pyridinium or trialkylammonium halides. The salts are prepd. by combining suitable alkyl halides with pyridine and morpholines, e. g., dodecyl pyridinium bromides from pyridine and dodecyl bromide, and are used in aq. soln. to which an addn. of gelatinizable substances, e. g., glue, gelatin, starch, gum arabic, isinglass, may be made. The emulsions may be used in leather dressing, as insecticidal sprays, in waterproofing, sizing and softening textiles, in wood impregnation or as disinfectants. Examples are given.

**Wetting agents, etc.** 1. G. Farbenind. A.-G. Brit. 394,043, June 22, 1933. Assistants for the textile and allied industries are obtained by the chlorination of sulfuric esters of (cyclo)aliphatic alcs. contg. at least 6 C atoms, or salts thereof. The ethers of polyhydric alcs. contg. at least 6 C atoms and a free OH group, e. g., the monodecyl and cetyl glycol ethers, and polyhydric alcs. contg. at least 6 C atoms, e. g., dodecanediol and 7,18-stearylene glycol, may be used as starting materials. Among examples (1) octadecyl alc. is sulfonated with  $ClHSO_3$  in  $CCl_4$  and then treated with Cl in the presence of a Hg-vapor lamp, (2) a mixt. of naphthenic alcs. is sulfonated and then treated with Br, the nonsulfonated alcs. being extrd. with  $K_2CO_3$ , and (3) lauryl alc. is sulfonated in  $CCl_4$  and treated with  $ICl_3$ . The products are wetting, foaming, dispersing and cleansing agents.

**Wetting agents, etc.** Deutsche Hydrierwerke A.-G. Brit. 394,196, June 22, 1933. See Fr. 743,594 (C. A. 27, 3789 90).

## 28—SUGAR, STARCH AND GUMS

J. K. DALE

A suggestion to sugar growers of the Philippines. A. H. Muzzall. *Sugar News* 14, 431 5(1933).—By taking advantage of the results of research in rubber growing, certain sugar soils can be profitably planted in rubber.

I. Cusachs

**Progress report on studies of milling tests.** B. B. Henderson. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 127 9.—There are various objections to the milling tests used in the past in Hawaii. A perfect milling test should be capable of being carried out while the mill is running normally, and without interfering with the grinding rate; sampling and analyses should be simple and not consume too much time; the test should give a result which can be definitely interpreted. With this line of reasoning as a basis, the extrn. of sep. milling units was detd. by finding the polarization and fiber in the bagasse from each mill. These tests at the beginning gave a satisfactory curve, but this could not be duplicated in subsequent tests. The work is being continued.

F. W. Zerban

**Milling control by juice density curves.** Raymond Elliott. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 141-4.—The d. of the juices of sep. milling units, and of front and back rollers, gives a useful indication of mill work efficiency. The curves representing such data should be established when the mill is doing its best work, to serve as a basis of comparison with similar curves obtained under different conditions of operation. Generally, a steep, practically straight curve is indicative of good work. The ratio between the d. of the last roller juice and that of the theoretical residual juice sol. solids in bagasse/[sol. solids in bagasse + water in bagasse] should be at least 0.55. High extrn. by the front roller compared to that by the back roller of a single mill also indicates good performance.

F. W. Zerban

**Cane and juice sampling of field experiments.** Ralph

J. Borden, et al. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 49-67.—For a reliable interpretation of the results of field tests it is necessary to det. not only the cane-yield differences of replicated plots, but also the quality ratio in the same manner, and not from combined cane samples. Unless the cane is sampled properly, it is better to make no juice analyses at all. The juice samples may be taken from under the crusher in various ways, but it is necessary that they be truly representative. Some automatic devices are described which make it possible to sample at the proper time the crusher juice from sep. lots of cane placed on the carrier, without blank spaces being left between the different lots.

F. W. Zerban

**Removal of colloids from diffusion juices by the action of lime in an electric field.** A. G. Arkhipovich. *Nauk. Zapiski Tsukrovoy Prom.* 10, No. 29/30, 97-102(1933).—The action of lime in diffusion juice is to neutralize the org. acids forming sol. and slightly sol. Ca salts and producing Ca saccharate; the lime saponifies the fats into insol. soap; araban and glucurone are partly pyrid. in the form of Ca salts of polyglucuronic acids. The undissolved lime adsorbs the colloids. All this can be obtained with a small amt. of lime (0.2-0.4%), but the filtrability of the juice in this case is very poor. The purity of the juices can be increased by 1-2 units if an electro-coagulator is used. Decreasing the amt. of lime decreases the purity of the juice. A temp. increase up to  $55^\circ$  is favorable. Expts. with dried beets showed an increase in purification of 1.5 units when electro-coagulation was applied. The increase of lime alone did not show any increase of purity. Therefore the creation of an elec. field in diffusion juices after adding the lime increases the activity of colloids and of the lime and a better purification is obtained.

V. E. Baikow

**Crystallization of beet sugar.** Karel Sanders. *Chimie &*

**industrie Special No.**, 1147-50 (June, 1933).—See C. A. 27, 2330.

**Determination of invert sugar in sugar-house products.** R. Oger. *Chimie & Industrie Special No.*, 1125-6 (June, 1933).—See C. A. 26, 3693.

**The application of Davies' method of determining chlorides in sugar products.** Mario Catenacci. *Ind. sucarr. ital.* 26, 458-9 (1933).—This method gives 0.49% Cl directly on the dil. molasses sample against 0.45 and 0.46%, after incineration, by the Vollard and Mohr methods, resp.

**The nature of the impurities of raw sugar crystals.** Ippolito Sorgato. *Ind. sucarr. ital.* 26, 449-57 (1933).—Cond. titration, with 0.05 N HCl, curves enable an evaluation of the org. and inorg. electrolytes. Comparative curves for the raw sugar, before and after affination, furnish a criterion of the impurities adsorbed by the sugar crystals.

**Vacuum pan volume calculations.** S. S. Peck. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 113-15.—The calcn. of pan-capacity demands can be simplified by referring all the figures to Brix or percentage of solids. Derr's formula gives in this case: Brix in sugar per unit Brix in raw material =  $(s - m) / (s - m)$  for low-grade calcns. the following formula may be used: Brix in low-grade sugar per unit Brix in sirup =  $[(s - j)(b - m)] / [(s - b)(r - m)]$  where  $s$ ,  $j$ , and  $m$  have the usual meaning,  $b$  is the purity of the low-grade pan, and  $r$  the purity of the low-grade sugar. Because of the return of low-grade sugar as seed or remelt the total low grade produced becomes a const. quantity after several cycles. The const. Brix in low grades per 100 Brix in sirup =  $[(s - j)(b - m)] / [(s - m)(r - b)] < 100$ . A graph is presented, giving this figure for varying purities of low-grade sugar and of sirup.

**Use of alloys in the sugar factory.** Edwin A. Rogers. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 153-5. Attention is called to the possible uses in the sugar factory of special steels, hard surface metals, and non-ferrous metals for various purposes, and the experiences in 3 factories with such materials are related.

**Correction for sugar introduced with bagasse in Oliver-Campbell filter operation.** S. A. Wickey. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 125-6.—To det. this correction it is necessary to find the wt. of bagasse screenings added. Samples are taken of the screenings, of the settlings from the clarifier, and of the filter cake. The percentage of total insol. solids is detd. in the last 2 giving  $S'$  and  $S''$ , resp., by filtering through cloth or paper, washing with hot H<sub>2</sub>O, drying and weighing. The percentage of fiber is detd. in all 3 materials by washing with tap water through a 100-mesh screen, drying and weighing; this gives  $F$ ,  $F'$  and  $F''$ , resp. Then tons of fiber added =  $[(\text{tons filter cake} \times S'') / 100] - [(\text{tons filter cake} \times S') / 100] / [(100 - (100 F' / S'))]$ . Tons of bagasse screenings =  $(100 \times \text{tons fiber added}) / F$ .

**Relative effect of trash on the factory operations.** Geo. D. Becker. *Repts. Assoc. Hawaiian Sugar Tech. 12th Annual Meeting 1933*, 11-14.—Three 7.5-ton samples of cane, without, with 8%, and with 16% trash, resp., were ground separately in the factory, and the usual analyses and other observations made. The results are shown in a table. The trash depressed the Brix and purity of all the juices. The boiler-house recovery was lowered from 94.51 to 93.96 and 93.18%, resp. The cane ratio increased, also the bagasse percentage of cane, but the fuel value of the bagasse from the cleaned cane was much higher. The tons of cane ground per hr. were less for the uncleaned samples. The estd. loss from 8% trash is over \$8000 per crop, from 16% trash over \$20,000.

**Field trash.** H. F. Hadfield. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 95-104.—On blumming plantations the trash carries a considerable amt. of absorbed water which affect; the d. of the 1st expressed

juice, and hence the calcd. wt. of the cane. New methods for detg. both field trash and the abs. juice factor are suggested for further trial by blumming plantations, because the present methods cause losses to the mill through excessive payments for cane.

**Entrainment.** James W. Donald. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 105-8.—When the drops of sirup in the vapor space of the evaporator become extremely small they are carried away through the usual catch-alls into the condenser, no matter how high the vapor space may be. In a given instance the crit. size of the drops was 0.1 mm. at 27 in. of vacuum. Entrainment was completely stopped in this case by installing in the last body of the effect a Heckmann foam separator, which consists essentially of an inverted funnel above the pipe of which a deflector plate is placed at the proper distance.

**Definition of terms which describe heavy chemicals.** R. Q. Smith. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 109-11.—Definitions of the following terms used in connection with chemicals which are employed in sugar factories (except lab. chemicals) are given: Baumé, Twaddell, water white, com. grade, degree of fineness and shape, package. The various com. grades of HCl, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, NaOH, Na<sub>2</sub>CO<sub>3</sub>, Ca(OH)<sub>2</sub> and H<sub>3</sub>PO<sub>4</sub> are briefly characterized.

**Filtration of oil from boiler feed water.** Ralph H. Johnson. *Repts. Assoc. Hawaiian Sugar Tech. 12th Ann. Meeting 1933*, 145-51.—When the steam consumption in sugar factories becomes high, some oil is always carried through the traps and causes trouble in the boilers. The oil may be removed by chem. coagulation, but this is expensive. Filtration has proved quite efficient for the purpose. It may be either gravity filtration in tanks through fine bagasse, cotton waste or excelsior, or else pressure filtration through heavily woven cloth, in so-called grease extractors of the Ross, Elliot or Cochran type. Filtration with Hyflo-Superel in Sweetland filters is still better, although the operating cost is a little higher.

**Crystallizer massecuite.** B. B. Henderson and G. H. W. Burnhart. *Repts. Assoc. Hawaiian Sugar Tech. 12th Annual Meeting 1933*, 131-40.—The purity of the final molasses may be lowered effectively by heating the massecuite prior to purging. Several methods for doing this are described. It is necessary, however, that the d. of the massecuite be reasonably high, and that diln. water be used sparingly. The massecuite should ordinarily not be heated above 135°F., to avoid local overheating. The low-grade grain must be fairly uniform. The temp. drop between the heater and the centrifugal should be small, as otherwise the viscosity will rise too high again.

**The partial removal of certain alkalies by zeolite from, and the effect upon the crystallization of sucrose and the viscosity of, final molasses.** R. H. King and Salvador B. Oliveros. *Sugar News* 14, 436-44 (1933).—Portions of dild. molasses were each percolated through sep. amts. of zeolite, activated with chlorides of either (1) Na, (2) K, (3) Mg or (4) Ca. The 4 percolates were concd., seeded with sucrose and placed in cry. tallizers; the mother liquors were sep'd and analyzed. Samples from 1 and 2 were higher in purity while 3 and 4 were lower than the control. The viscosities were inversely related to the purities.

**Studies on the cause of molasses formation. II. The equilibrium of the ternary system of sucrose-water-sodium carbonate or potassium carbonate at 30° and the viscosity of the coexisting liquid phase.** Kyosuke Nishizawa and Marataka Amagasa. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 497-501 (1933); cf. C. A. 25, 5790.—The ternary equil. diagrams for both carbonates and a solv. diagram are presented. A new stable compd., C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>Na<sub>2</sub>CO<sub>3</sub>, was observed. Addn. of carbonates resulted in an initial slight decrease of the soly. of sucrose to a min. pt., and then a sudden increase, with an ac-

accompanying marked increase in the viscosity of the coexisting liquid phase. The K salt increased the soly. of sucrose more than the Na salt. The transition points of the carbonates were displaced by the addn. of sucrose and crystals with different waters of crystn. than in pure water exist as stable solid phases.  $K_2CO_3 \cdot 1.5H_2O$  and  $Na_2CO_3 \cdot 7H_2O$  were the stable forms chiefly encountered in the presence of sucrose at 30°. The relative viscosities of the liquid phases of the carbonate solns. were very greatly influenced by sucrose addns. but not so the relative satns. as seen from an accompanying plot. The properties of the new compd. are described. III. The equilibrium of the ternary system of sucrose-water-sodium acetate or potassium acetate at 30° and the viscosity of the coexisting liquid phase. *Ibid.* 501-4. — Ternary diagrams, a soly. diagram and curves for relative viscosities and satns. are presented. Addns. of NaOAc decreased the soly. of sucrose by about 10% at approx. 15% salt content, while KOAc did not show any such decrease; after the min. point the increase for both salts is quite sudden and that of the K salt is more pronounced. In sucrose solns. NaOAc  $\cdot 3H_2O$  existed as the stable solid and its soly. increased regularly with the sucrose content, and 2[KOAc]  $\cdot H_2O$  was the main stable compd. which had its soly. increased in a like manner. Although no compds. of sucrose and acetate could be found the authors believe that such might exist. As with carbonates the relative viscosities of the liquid phase were much more affected than the relative satns., with the K salt being the more effective one. Kari Kammermeyer

Hydrogenolysis of sugars (Zartman, Adkins) 10.  $\beta$ -Lactose (Greenleaf) 12. Evapn. and its applications [in the sugar industry] (Lafitte) 13. Mixed fertilizers and the sugar beet (Decoux) 15. Mannitol fermentation of levulose (Bulcato) 16. Starch (Hess) 10. Sugars (Ir. pat. 729,205) 23. Centrifugal machine for purifying crude starch, etc. (Brit. pat. 394,811) 23.

Counterflow extraction apparatus for sugar, etc. Rafinerie Tirkemontaise Soc. anon. Ger. 579,726, June 30, 1933. Addn. to 578,025 (C. A. 27, 4436). This corresponds to Brit. 365,007 (C. A. 27, 3840).

Apparatus for saturating sugar juices. Fritz Blanke. Ger. 579,966, July 3, 1933. Addn. to 559,048 (C. A. 27, 1228).

Sterilizing and purifying sugar liquids. Gaston Durct. Brit. 395,527, July 20, 1933. Sugar-contg. juices are neutralized or made slightly alk. (cf. C. A. 27, 1540) when sugar is manufd. or made slightly acid, e. g., with HCl,  $H_2SO_4$  or HF, when alc. is manufd. and finally maintained at below 35° in a sterile condition under a layer of an insol. or slightly sol. antiferment, e. g.,  $C_6H_6$ , PhMe, PhEt, xylene, the antiferment being periodically mixed with the juice. The sterilization with ultra-violet light may follow the acidification or alkalization.

## 29 LEATHER AND GLUE

ALLEN ROGERS

Scientific activity of the French Section of the International Leather Industry Chemists Society. P. Vignon. *Chimie & industrie* Special No., 1107 10 (June, 1933). A review of work published during the year 1931-32.

A. Papineau-Conture

Investigating the conditions of infestation of hides with *Dermestes lardarius* and *Dermestes frischii* and measures for their destruction. L. I. Evremova. *Ovladenie Tekhniki: Koshobuynoe Proizvodstvo* 1932, No. 4, 11-5. — The habits of these parasites found in hide storehouses are described. The following insecticides were tried: Schwemfurt green, Na arsenate and arsenite, BaCl, bisulfite, bisulfate,  $CS_2$ , chloropierin, *p*-dichlorobenzene, naphthalene, kerosene, turpentine, kerosene + turpentine (1:1), gasoline and  $CCl_4$ . A complete extermination was obtained with kerosene and kerosene + turpentine, 1:1 being used for 200 dry skins. Schwemfurt green, Na arsenite, chloropierin and  $CS_2$ , although being 100% efficient, are not recommended because of their toxicity to human beings. The hides are sprayed individually with one of the above insecticides and *p*-dichlorobenzene powder is sprayed between the hides when they are placed back in storage.

A. A. Bochtlingk

Influence of the preparation methods and of sulfitation on the tanning and physicochemical properties of pine extracts. E. A. Zobina, N. S. Krasnikova and A. N. Mikhailov. *Ovladenie Tekhniki: Koshobuynoe Proizvodstvo* 1932, No. 3, 38-9. — The investigation was carried out for the purpose of detg. the best conditions for the prepn. of sulfited pine exts., as well as for defining the influence of temp. on the extn. of pine bark and the influence of concn. on the quality of the ext. To det. the best sulfitation conditions expts. with a liquid pine ext. obtained by the extn. of pine bark at 80-90° and treated with sulfite, bisulfite,  $Na_2CO_3$  and their mixts. were undertaken. The best sulfitation results were obtained with  $\frac{1}{4} Na_2SO_3 + \frac{1}{2} NaHSO_3$ , the amt. of the reagent being 5% of the dry substance, the pine ext. being first treated with sulfite for 4 hrs. at 90-95°, then with bisulfite also for 4 hrs. at 75-85°. The influence of the temp. during the extn. was investigated by extg. the pine bark at (1) a temp. not exceeding 50°, (2) at 90-95° in all diffusers and (3) at 90° in the first and 120° in the last diffuser and with 5° intervals in the intermediate diffusers.

The concn. was carried out *in vacuo* up to 20-22°Bé. The investigation covered sulfited as well as unsulfited exts. Results: (1) An increase of the extn. temp. up to 120° does not affect the diffusion of the ext. (2) Sulfitation of the ext. improves its diffusion properties in all cases. (3) Its tanning properties do not deteriorate on concg. the ext. to the consistency of dough. A complete diffusion was not attained in all cases. The binding properties of the ext. decrease on sulfitation (Crede coeff.), while they improve on heating. The tannides are more stable against salting out on sulfitation. The surface tension of all the exts. was the same, amounting to 0.73-0.76 toward water. An increase of the extn. temp. causes a higher viscosity at high concns. and the total acidity as detd. by the Steven and Anker dialysis decreases on sulfitation at elevated temp.

A. A. B.

Improving low-quality oak and other extracts. S. S. Vovutskii. *Ovladenie Tekhniki: Koshobuynoe Proizvodstvo* 1932, No. 3, 39-40. — This investigation was carried out to det. the advisability of pptg. the tannide from spent exts. followed by a regeneration of the tanning substance. The following methods were investigated: (1) with lime water instead of milk of lime for precipitant; (2) fractional pptn. of tannides with  $Ca(OH)_2$  and prepu. of exts. from individual fractions; (3) detg. the possibility of using  $Ba(OH)_2$  for precipitant. It was found that the yield of tannides as well as the quality of exts. is improved on using the lime water instead of milk of lime pptn. method, while the amt. of  $H_2SO_4$  as well as of lime can be lowered three-fold. Poor-quality lime can be used when applying lime water, a lime which would be unsuitable for milk of lime pptn. A fractional pptn. showed that an ext. of a higher quality can be obtained on incompletely pptg. the tannides. The yield as such is lowered although the unpptd. tannides which remain in the soln. can be pptd. by a new portion of lime and after regeneration they may be used for prepg. a second-grade ext. Pptn. with  $Ba(OH)_2$  instead of lime produced an ext. with a very low ash content.

A. A. B.

Combining tannides of sulfite cellulose extracts "TzNIKP" No. 4 and "TzNIKP" No. 5 depending on the pn during tanning. T. I. Korotnev. *Ovladenie Tekhniki: Koshobuynoe Proizvodstvo* 1932, No. 4, 44. — To develop a tanning method for sulfite cellulose tannides

of various brands, the conditions for the best combination of collagen with tannides must be detd. This condition is complied with by detg. the  $pH$  factor during the tanning. Thus 40 g. of an American hide powder was moistened with 10 vols. of distil.  $H_2O$  for 4-5 hrs., followed by pressing out 25% of the water present and placing it in ext. solns. of TzNIKIP No. 4 and TzNIKIP No. 5 having a concn. of 52 g. of tannides per l., corresponding to 10°Bé. for TzNIKIP No. 5 at a  $pH$  of 1.5, 2, 2.5, 3, 4.5, 6 and 10. The  $pH$  concn. was adjusted by adding 2 N HCl or 2 N NaOH and the detn. was carried out with a freshly palladized electrode. The powders were tanned for 3 days, dried at 25-30° and the following detns. were made:  $H_2O$ , ash, hide substance, sol. org. and inorg. substances and resistance to  $H_2O$ . The substances which were washed out from the powder were detd. 4 days after the tanning. It was found that the max. of combination for sulfite cellulose exts. TzNIKIP No. 5 and TzNIKIP No. 4 lies at  $pH$  2. The max. of the water-resistance curves was found at  $pH$  2.5, which would amount to 87.2 for TzNIKIP No. 5 and 78.17 for TzNIKIP No. 4. The min. of the isoelec. point and the second max. was at  $pH$  10. In the investigation of the influence of  $pH$  on the analysis of the tanning solns. at an analytical concn. of 4 g. per l. arbitrary curves showing the amt. of tannides decrease with increase of  $pH$ . A. A. B.

**Preparing and bleaching reptile leather.** Ya. N. Kaplinov and V. N. Semenova. *Ovladenie Tekhniki Kozhevennoe Proizvodstvo* 1931, No. 2, 18-19.—The following procedure is recommended. Soak in 5 parts  $H_2O$  at 15-20° for 20 hrs. Lame with  $H_2O$  500% of the wet leather, CaO (50%) 10 g. per l.,  $Na_2S$  (62%) 2 g. per l. for 4 days at 15° for lizard skin and for 3 days for snake skin. Delime with  $H_2O$  300%,  $NaHSO_3$  2%, HCl 0.25% of the wt. of the raw skin at 35° for 1 hr. Soften with HCl 400%, oropon  $MO_2$  0.5% of the raw skin at 35°. For vegetable tanning treat with sumac soln. of 0.3° Bé. in the first and 3° Bé. in the last vat (4° Bé. for lizard skin in the last vat) for 4-5 days. Bleach with acetic or oxalic acid, fat liquor with an emulsion of alizarin oil (2%), castor oil (2%), preserved egg yolk (3% with 10% fat) and  $H_2O$  100% of the tanned skins, at 35° for 20-30 min. For formalin-chrome tanning give a preliminary treatment with  $H_2O$  200%, formalin 3%, add to the same soln. after one hr.  $Na_2CO_3$  4% and  $H_2O$  50% of the second wt. of the skin and let stand 2 hrs. Then treat with  $H_2O$  200% and  $Cr_2O_3$  2.0% of the 2nd wt. of the skin, having a basicity according to Schorkemmer of 35%. Neutralize, fat liquor and finish. For S-chamoise tanning, the skins are pickled for one hr. after softening in a soln. of 3% HCl, 150%  $H_2O$ , 10% NaCl. The thiosulfate bath is prep'd. from 150%  $H_2O$ , 5%  $Na_2S_2O_4$  and 6% NaCl of the 2nd wt. of the raw skins; duration 1-1.5 hrs. For chamoise tanning use  $H_2O$  40%, alum 7%, flour 10%, NaCl 3%, egg yolk 20% (with 10% fat), dry and finish. The lizard leather prep'd. by one of the above methods has a breaking strength of 2.18 kg. per square mm. when dry and 1.70 kg. per square mm. when wet.  $KMnO_4$  is the best bleaching agent. A. A. B.

**Determining the total sulfur in leather by the combustion method in a calorimetric bomb.** Ya. P. Berkman and T. S. Basal-Kudish. *Ovladenie Tekhniki: Kozhevennoe Proizvodstvo* 1932, No. 5, 38-9.—The following procedure is recommended for detg. total S in leather in the absence of trivalent metals. (1) The leather is broken up into pieces of 1 cu. m. of which about 1 g. is used. It is compressed in the usual manner and the briquet is weighed and placed in a Pt or  $SiO_2$  crucible in a bomb charged with 10 cc. of a 10% soln. of alkali. The  $O_2$  pressure is brought up to 20-25 atm., the sample burned in the usual manner, the bomb placed in water and the gas released with care. The contents of the bomb are transferred into a beaker, the bomb is rinsed and the soln. added to that in the beaker. The caustic soln. is oxidized with Br water, heated to boiling, acidified with HCl, boiled for 30 min. to remove the Br and filtered.  $SO_2$  is detd. in the filtrate in the usual manner. It was found that concordant results are obtained by this method and that

they are as a rule higher than those obtained in the Baland-Maljean method and that the deviations of the results obtained by the above methods have no relation to the  $SO_2$  content. The analysis of total S in a leather contg. Cr should be carried out as follows: The preliminary prep'n. (1) of the sample is as usual but the pressure in the bomb is brought up only to 8 atm. (2) The soln. of alkali and the washing water are handled in the same way as before. (3) The ash is fused with the oxidizing mixt., the melt dissolved in  $H_2O$  and S is either directly pptd. as  $BaSO_4$  or in an acidic medium with a correction for  $BaCrO_4$  or it may be first reduced to remove Cr. The total S is that contained in (2) and (3). Conclusion: The total S in leather can accurately and rapidly be detd. by combustion in a calorimetric bomb. The analytical procedure is described. A. A. B.

**Determination of the moisture content of leathers.** V. Kubelka, V. Nemeš and S. Zuvavlev. *Chimie & Industrie Special No.*, 1111-16 (June, 1933).—See C. A. 27, 2334. A. Papineau-Couture

**Determining the moisture and fat in leather by the Pryanishnikov method.** K. M. Platinov. *Ovladenie Tekhniki: Kozhevennoe Proizvodstvo* 1931, No. 1, 34-5.—The Pryanishnikov method (C. A. 23, 1503) was applied to leather by use of a mixt. of gasoline and 6% iso-Bu alc. The results when applied to red tanned leather were too low in  $H_2O$  and too high in fats for chrome-tanned leather. A. A. Bochtlingk

**Adsorption and swelling. IV. Influence of temperature on the swelling of hide powder.** V. Kubelka and V. Sumec. *Chimie & Industrie Special No.*, 1117-19 (June, 1933). See C. A. 27, 4436. A. P.-C.

**Change in the isoelectric point of collagen under the action of trypsin.** N. I. Gavrilov and A. M. Smaskaya. *Ovladenie Tekhniki: Kozhevennoe Proizvodstvo* 1931, No. 2, 23-4.—The object was to study the reactions that take place in leather under the influence of the enzyme during bating. The albumin mols. of the collagen may be converted from keto to the enol form and the latter may exist in two isomers: the  $\alpha$ , which may be obtained by the transition of the unstable H from the N, and the  $\beta$ , which utilizes the unstable H of the adjacent C. Both enols have acidic functions. This explains the formation of the enol form from the neutral keto form, which must be accompanied by an increase in the acidity of the whole compd., i. e., by a shift of the isoelec. point in the direction of acid. It was assumed that the isomerization of the peptide bond in the collagen from the keto to the enol form takes place under the influence of trypsin. The middle layer of a hide, consisting of almost pure collagen, was ground to powder. Detns. were made of the isoelec. point of the unlimed powder and of the powder after treatment with trypsin, oropon and water at  $pH$  7.8-8.1 and 8°. For the isoelec. point was selected a concn. of H ions at which the content of the Ca in collagen is lowest. The isoelec. point of collagen changed under the influence of trypsin in the acid direction from  $pH$  4.64 to  $pH$  3.7 and under the influence of oropon to  $pH$  3.4-4.2, depending upon the duration of bating. A. A. Bochtlingk

**Study of dressing buhrstone mills.** Baltimore Paint & Varnish Production Club, *Am. Paint J.* 17, No. 53A, 16-17; *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 445, 432-7; *Paint, Oil & Chem. Rev.* 95, No. 22, 64-6 (1933).—The factors affecting the output of a buhrstone mill are no. of sectors, angle and points of intersection, speed; those affecting the fineness of the grind are angle of intersection and length of the shearing crack. A device for dressing buhrstone mills is described. G. G. S.

**Siberian larch [use in tanning]** (Gordon) 22. Trisazo dyes [for leather] (Ger. pat. 582,399) 25. Decompn. products of albumin [for treating leather] (Pr. pat. 749,228) 25. Rubber coating compns. [for leather] (Brit. pat. 392,797) 30.

**Bergmann, Max:** *Gesammelte Abhandlungen des Kaiser Wilhelm-Instituts für Lederforschung in Dresden.*

Bd. IV. 1930 bis 1932. (Berlin: J. Springer. 520 pp. 1 M. 46 bound.

**Tanning solution.** Otto Röhm. U. S. 1,930,910, Oct. 17. Fe salts contg. a trivalent cation such as Fe sulfate-chloride are used with esters of phosphoric acid such as glycerophosphoric acid. Alum or Cr chloride, etc., also may be used.

**Leather.** I. G. Farbenind. A.-G. Brit. 388,091, Feb. 23, 1933. Tanning and other  $H_2O$ -sol. substances of high mol. wt. that contain acid groups in free, esterified or salt state, and also fatty substances and dyes, are pptd. in hides by treatment with  $H_2O$ -sol. complex hexa-urea chromic salts having the formula  $CrY_3X_3$ , where Y is urea and X is a monobasic acid radical. The complex salts are obtained by reaction of an alkali salt of the acid with hexa-urea chromic chloride which is obtained by evapg. an aq. soln. of urea and  $CrCl_3$  in requisite proportions. The treatment may be before or after tanning or after greasing, etc. Substances that do not form a ppt. with the complex salts may be used in conjunction therewith, e. g.,  $AcOH$ ,  $HCOOH$ , oxalic acid,  $Al_2(SO_4)_3$ ,  $MgSO_4$ , pink salt, etc., and also substances capable in excess of dissolving any ppt. formed, e. g., org. sulfonic acids. Among examples skins are pretanned with a condensation product of naphthalenesulfonic acid and  $CH_2O$  with the addn. of hexa-urea chromic chloride and afterward treated with a mixt. of wattle bark, chestnut wood and sulfitized quebracho.

**Leather from green hides.** Robert W. Chandler (to Graton & Knight Co.). U. S. 1,930,158, Oct. 10. The hide is subjected to mineral tanning, impregnated with sol. stuffing material and a sealing ingredient such as phenolic resin varnish and heated to convert the sealing ingredient into a product normally insol. in media with which the leather may come into contact so as to protect the stuffing against such media and to strengthen and reinforce the finished leather.

**Patent leather.** E. I. du Pont de Nemours & Co. Brit. 391,000, June 19, 1933. In making patent leather the final coating comprises a drying-oil-modified poly-

hydric alc.-polybasic acid resin. Leather is coated first with a mixt. of bodied linseed oil, i. e., oil heated to 550–600°F. in the absence of driers, and a pigment; 2 or 3 coats of a clear varnish consisting of a bodied linseed oil thinned with naphtha are then applied. Nitrocellulose may be added to these undercoats. Finally a soln. of the said resin is applied and dried 10–20 hrs. at 150–175°F. Suitable resins are made from glycerol, pentaerythritol or polyethyleneglycol with phthalic anhydride or succinic, fumaric, maleic or adipic acid and linseed, chinawood, perilla or soy-bean oil. Drying oil acids may be used instead of drying oils. Optional addns. include rosin or resin acids, monohydric alcs., e. g., benzyl alc., polyhydric alcs., e. g., ethyleneglycol, glycol ethers, xylene, naphtha, terpene, turpentine substitutes and driers, e. g., Co, Pb, Mn and Fe linolates.

**Leather substitute.** Leonard Boudy. U. S. 1,931,428, Oct. 17. Fibrous material such as cotton, jute or "wood-wool" is freed from greasy matter, dried and incorporated with a powd. mixt. of slaked lime, sandstone, resin, pumice stone and emery, and the material is then subjected to the action of a liquid bath comprising latex, ammonia, pure water and a weak soln. of carbolic acid, and may be formed into sheets. Cf. C. A. 27, 5575.

**Gelatin, etc., compositions.** Robert P. Rudin. Brit. 390,543, Apr. 13, 1933. A substance for receiving sound, etc., record impressions by direct cutting of a recording stylus and which is subsequently hardened chemically consists of colloid materials such as glue to which is added 0.2–25% of chem. compds. that are not vaporizable without decompn. and have a high b. p., e. g., glycol or glycerol or their derivs., *p*-methoxypyridine, for the purpose of reducing the hardness. The adhesiveness and elasticity are then removed by adding compds. which may form a component of the means for the subsequent hardening, e. g., certain simple or substituted sugars, particularly pentagalloylglucose. After recording, the substance can be hardened by treating with a hardening fluid such as a dichromate or aldehyde soln.

**Machine for making capsules from gelatin.** Robert P. Scherer. Brit. 395,546, July 20, 1933.

### 30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

**Review of developments and progress in the chemistry and technology of latex and of rubber from 1927 to July, 1932.** St. Reiner. *Caoutchouc and gutta-percha* 30, 16542 4(1933); cf. C. A. 27, 4124.—Numerous patents on the direct application of latex to various products are cited.

C. C. Davis

**A new technic in the rubber industry.** J. Ch. Bongrand. *Chimie & industrie Special No.*, 1080 4(June, 1933).—See C. A. 26, 4721.

A. P. C.

**Determination of rubber in rubber-bearing plants.** D. Spence and M. L. Caldwell. *Ind. Eng. Chem., Anal. Ed.* 5, 371–5(1933).—Extensive expts. on various methods of detg. the rubber content of plants, in which all the factors influencing the results were studied in detail, showed that all known methods give either incomplete extn. or an impure rubber. The most important factors are respiration changes in the plant tissue after harvesting, colloidal substances in the plant tissue upon extn., oxidation during drying of the ext. and the solvent. As a result of this exhaustive study, a new method was developed which removes the rubber completely in a pure form. It involves grinding, treatment with boiling 1%  $H_2SO_4$  and steam (30 lb. per sq. in.), washing, acetone extn., extn. with  $C_6H_6$ , and drying of the ext. In the final drying the addn. of a known quantity of dimethyl-*p*-phenylenediamine prevents oxidations and increases the precision, and it is suggested that the use of antioxidants in chem. analysis should be capable of wide application where org. compds. susceptible to oxidation are encountered. Analysis of the final product from guayule indicated a hydrocarbon of the compn.  $(C_6H_8)_n$ .

Though the work was carried out with guayule shrub, the method should be applicable to other plants contg. rubber

C. C. Davis

**Estate practice and its relation to factory requirements.** F. B. Jones. *Trans. Inst. Rubber Ind.* 9, 112–22(1933).

A crit. discussion of the variability of plantation rubber. Tests of the rate of vulcanization of slowly curing and quickly curing smoked sheets in a rubber-S (90:10) mixt. showed optimum times of cure of 140 and 80 min., resp., at 147°. In mixts. accelerated with mercaptobenzothiazole and with  $MgO$ , the rubbers still showed wide differences. Scorching tests where the change in recovery was measured with a parallel-plate plastometer showed that recovery is a satisfactory criterion of the true plasticity, but that plasticity is not a certain criterion of behavior during processing. However, the recovery test can be used to judge prevulcanizing by heating pellets for increasing times at a temp. which ultimately causes vulcanization and measuring the recovery. At a crit. time the percentage recovery increases disproportionately fast, irrespective of its original magnitude. Tests by this method show that variations in raw rubber, as shown by rubber-S vulcanizates, may persist when org. accelerators are included. Means for minimizing on the plantations the variability of raw rubber is discussed.

C. C. Davis

**Investigation of the physicommechanical properties of rubber.** M. O. Segal. *Otlozhenie Tekhniki: Konobuovnoe Proizvodstvo* 1932, No. 4, 38–41.—The following tests of shoe-sole rubber are reported: d., uniformity of thickness and shape, tensile strength when moist and

dry, and after keeping in a thermostat at 50° and 70°, swelling, air permeability, water permeability, deformation by water diffusion followed by drying, hardness, wear by rubbing, holding of screws and resistance to punching and removing a needle. A. A. B.

Products of porous rubber. St. Reiner. *Caoutchouc and gutta-percha* 30, 16546 7(1933).—A description of tech. problems in the manuf. of various types.

C. C. Davis  
Rubber in highway service construction. Program of research. R. G. H. Clements, et al. *Bull. Rubber Growers' Assoc.* 15, 489 96(1933).—A detailed outline of research to be carried out on rubber road-surfacing mixts., including the character and scope of the investigation, the essential properties of a good road surface, (durability, stability, resilience, coeff. of friction, resistance to traction, vibration, sound absorption, adhesion, light-reflecting power) and tests to det. and control these properties, and the properties and behavior of various types of materials best suited for use in conjunction with rubber. C. C. Davis

Antioxygens P. Jacobs. *Caoutchouc and gutta-percha* 30, 16548-50(1933); cf. *C. A.* 27, 3357. —A tabulation of the chem. name and formula, com. name, properties and behavior as accelerators of various phenols, amines amino-condensation products. C. C. Davis

The action of anti-aging agents. B. Dogadkin. *J. Rubber Ind.* (U. S. S. R) 5, No. 6, 11-21(1931); *Chem. Zentr.* 1932, I, 1959. —Attempts were made to develop methods by which some insight could be gained into the mechanism of the stabilization of rubber by means of anti-aging agents. Illumination with the quartz lamp changed the properties of raw rubber by photochem. action. The curves showing the decrease in viscosity of a crepe soln. in toluene for various periods of illumination were plotted. The viscosity of a 1% soln. diminished to a limiting value in 1 hr. Bubbling air through the solns. had no influence on the viscosity curves, which indicates that any oxidation of the rubber is accomplished by the small quantity of O dissolved in the toluene soln. Of the stabilizers used, phenol, stearic acid and cumene were without influence; benzaldehyde accelerated the decomposition of rubber. Further expts. included a phenolic substance with a long side chain and a yellow azo dye (nothing more definite given). In contrast to "aldamin," the stabilizing action of the azo dye was independent of the concn. of the rubber. The action of "aldamin" appears to depend upon both chem. and optical properties. A theory of the mechanism of stabilization, based on the expts., is offered. M. G. Moore

Development of a method for the chemical and physical analysis of rubber plates. M. I. Sametnik. *Otdelenie Tekhniki: Koshobuynoe Proizvodstvo* 1932, No. 4, 36-9. After a review of methods covering the detn. of pigments, softeners, fillers, accelerators for improving mech. properties, and accelerators of vulcanization, and of methods for detg. chem. ingredients, the following scheme is presented. The rubber is extd. with acetone, and the following detns. are then made: ash, mineral components, C black, cellulose, factice, total S, Sb<sub>2</sub>S<sub>3</sub> and Hg. The soln. is comd. and the ext. analyzed for free S, mineral and vegetable oils, paraffin, vegetable resins, org. accelerators, white and black factice and waxes. Free S and unsaponifiable matter are detd. in the ext. The residue is extd. with CHCl<sub>3</sub> and the soln. is tested for bituminous substances and rubber particles (if the rubber is highly depolymerized). The residue obtained by extn. with CHCl<sub>3</sub> contains rubber combined with S, C black, cellulose, factice and mineral ingredients. A. A. Bochtlingk

The behavior of rubber-lined apparatus toward organic solvents. A. Bresser. *Synthetic and Applied Finishes* 4, 225(1933).—The results of exposure of a com. rubber coating (on metal) to 16 solvents of interest in the lacquer and plastic industries are described. The compn. and character of the rubber are not, however, mentioned. C. C. Davis

Accelerators of vulcanization. F. Jacobs. *Caoutchouc*

and gutta-percha 30, 16541-2(1933); cf. *C. A.* 27, 4128. —The properties and behavior of certain aldehyde-amines are described. C. C. Davis

Studies on the nature of the action of organic accelerators for rubber vulcanization. VII. The effect of heat on the surface tension of rubber solutions. Keiichi Shinada. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 450-4(1933); cf. *C. A.* 27, 4128. —The prepn. of the rubber solns. and the exptl. equipment are described and exptl. results are reported. The change of surface tension of purified pale crepe-xylene and smoked sheet xylene on heating was investigated and a progressive rise of the relative surface tension with increasing heating periods was observed, which S. believes to be due to depolymerization of the mols. The relative surface tensions of purified rubber-benzene, -toluene and -xylene solns. were studied stalagmometrically as a function of concn. at the boundary surface of the gaseous phase in order to ascertain the state of rubber in soln. and the structure of rubber solns. At the boundary air-benzene, -toluene and -xylene pure rubber behaves like a capillary-active substance up to 0.9% concn., and the isotherm of the relative surface tension shows a min. between 0.5 and 0.7% concn., which is due to the fact that dil. rubber solns. up to 0.7% concn. contain mainly free colloidal rubber mols., while at higher concns. aggregation takes place with the distinct appearance of a micellar structure. This is in support of the chem. depolymerization theory for the change of surface tension of dil. rubber solns. on heating and the accompanying lowering of viscosity. K. K.

Accelerators with a retarded action. F. Jacobs. *Rev. gén. caoutchouc* 10, No. 94, 33-8(1933); cf. *C. A.* 27, 4128. —More data on "Vulcacit J" are presented. C. C. Davis

Scorching of different accelerators. B. Pabritzhev and R. Shabanova. *India Rubber J.* 86, 363 7(1933). —See *C. A.* 27, 4954. C. C. Davis

Are hot-vulcanized dipped rubber goods detrimental to health? Werner Fsch. *India Rubber J.* 86, 303-4(1933). —See *C. A.* 27, 4128. C. C. Davis

The chemistry of soft rubber vulcanization. II. The function of sulfur. B. S. Garvey, Jr. and G. Thompson. *Ind. Eng. Chem.* 25, 1292 7(1933); cf. *C. A.* 27, 6018. —When crude raw rubber is heated with S, 2 reactions take place, either of which can bring about vulcanization: (1) a direct addn. of the S to the double bonds, and (2) a reaction at the double bonds of the hydrocarbon, which does not involve any change in the unsatn. of the latter. The changes in phys. properties during vulcanization are the result of a building-up of a mech. structure, and the phys. properties of the vulcanizate depend to a considerable extent upon the relative rates at which the 2 reactions take place and therefore upon the character of the structure formed by the 2 reactions. S catalyzes the 2nd reaction, whether or not accelerators are present, while accelerators influence both reactions. The relative effects on the 2 reactions probably depend upon the particular accelerator, the accelerator-S ratio and the temp. of vulcanization. In ordinary "soft rubber" vulcanizates, both reactions take place. With high proportions of accelerator and relatively low S the properties of the vulcanizates depend almost solely upon the non-S reaction, whereas the character of hard rubber depends primarily upon the combination of rubber and S. C. C. Davis

Effect of temperature and frequency on the dielectric constant, power factor and conductivity of compounds of purified rubber and sulfur. A. H. Scott, A. T. McPherson, Harvey L. Curtis and A. D. Cummings. *Bur. Standards J. Research* 11, 173-209(1933) (Research Paper No. 555). —The dielec. const., power factor and cond. of purified rubber and of a series of vulcanized rubber-S mixts. were detd. at -75° to 235°. Vulcanization was carried to a point where practically all S was combined. The dielec. const. and power factor were measured at 5 frequencies from 60 to 300,000 ~, and the apparent cond. at approx 0.002 sec. and at 1 min. after application of the potential. The results are given in tables and graphs. At

25° and 1000 ~, the dielec. const. of purified rubber contg. no S was 2.37. With increase in S content, the dielec. const. increased to a max. of approx. 3.75 at 11.5% S, then diminished to a min. of 2.70 at 22% S, and again increased to 2.82 at 32% S. Under similar conditions, the power factor increased from  $1.8 \times 10^{-3}$  for rubber alone to a max. of  $93.8 \times 10^{-3}$  at 13.5% S, then diminished to approx.  $4.0 \times 10^{-3}$  at 20% S, and again increased slowly to  $5.1 \times 10^{-3}$  at 32% S. The 1-min. cond. was  $2.3 \times 10^{-17}$  mho per cm. for rubber alone. With 12% S it was only  $0.5 \times 10^{-17}$ , while at 18% S it passed through a sharp max.  $38 \times 10^{-17}$ , then diminished to values between  $1$  and  $1.5 \times 10^{-17}$  for mixts. of 23–32% S. Changes of the temp. or the frequency at which the measurements were made shifted the maxima and minima of these curves and changed their heights. Thus at –25°, the max. dielec. const. at 1000 ~ was 2.8, which was obtained with a mixt. contg. 4% S. At 145° the max. was 4.5, with a mixt. contg. 26% S. A comparison of the results of this investigation on purified rubber with previous expts. on crude rubber (cf. C. A. 22, 330) indicates that purification alters the elec. properties but does not alter the general manner in which these properties vary with changes in compn., temp. or frequency. The results may have a practical bearing on the formulation of rubber mixts. for sp. uses. They also indicate the manner in which the properties of rubber are related to temp. or frequency, and show the inadequacy of the sample numerical consts. sometimes employed to evaluate changes in elec. properties with temp. and frequency.

C. C. Davis

**Mechanism of rubber aging.** Bernard L. Johnson and Frank K. Cameron. *Ind. Eng. Chem.* 25, 1151–2 (1933). — Vulcanizates of rubber, S, tetramethylthiourani monosulfide, stearic acid and ZnO, with and without phenyl- $\beta$ -naphthylamine, were examd. by x-rays before and after aging for 10 days in air at 70°. On aging, the intensity of the diffraction lines decreased progressively, whereas their position did not change. The increasing elongation required to produce fibering as rubber deteriorates depends upon the fact that it is necessary to expel an increased concn. of lower polymers formed from the cryst. aggregates or fibers by depolymerization during aging. The aggregates or fibers can then diffract x-rays. Oxidation may, however, give the same effect by obstructing in some way the elongation of tangled mols. or nuelles. A curve of the elongation at which the cryst. form first appears as a function of the time of aging gave evidence of the rate of depolymerization of the vulcanizates studied. The curves for the vulcanizates with and without phenyl- $\beta$ -naphthylamine were similar, which indicates that such an antioxidant does not influence the rate of depolymerization or the elongation necessary to produce fibering in deteriorated rubber. Bary and Fleurent have also found evidence of depolymerization during aging (cf. C. A. 21, 2398).

**Suggestion to sugar growers of the Philippines** [rubber growth in sugar soils] (Muzzall) 28. Multiform plastimeter (Lefcaditis, Avey) 1. Rubberized fabric (U. S. pat. 1,929,368) 25. Rubber coated fabric (U. S. pat. 1,931,110) 25. Puncture-sealing compns. (Brit. pat. 394,978) 18. [Rubber] printing-surfaces (Brit. pat. 395,214) 18. Leaching system for removing vulcanizing agents, etc., from materials (U. S. pat. 1,929,927) 13.

**Stabilizing latex.** Philip Schidrowitz and Pirelli Ltd. Brit. 395,066, July 13, 1933. Concd. latex, particularly that to be used for heat-deposition processes described in Brit. 284,808 (C. A. 22, 4877), 292,964 (C. A. 23, 1527), 330,520 (C. A. 24, 8063) and 351,012 (C. A. 26, 4505), is stabilized against thickening, or reduced in viscosity without diluting the disperse phase, by adding small quantities of piperidine,  $Et_3NH$ ,  $Me_3NH$  or like strong org. base, preferably in aq. soln.

**Rubber coagulum.** Frank O. Woodruff (to Harry H. Beckwith). U. S. 1,929,544, Oct. 10. A water-sol. gum such as gum arabic is dissolved and then mixed with a smaller quantity of mineral oil and the mixt. is passed

through a colloid mill to form a stable emulsion. The resulting mixt. is added to a quantity of latex contg. a wt. of rubber equal to the combined wts. of the gum and oil in the mixt. and the mixt. is coagulated by stirring with a quantity of 40% formaldehyde soln. equal in wt. to about 2% of the oil and solids in the mixt. The product thus prep'd. is suitable for making vulcanized products of good strength.

**Rubber compositions.** Harold A. Morton. U. S. 1,929,580, Oct. 10. "Age resisting" properties of rubber compns. are improved by addn. of about 1.0–1.5% of compds. such as a hydroglyoxaline selected from a class consisting of 2,4,5-trifuryldihydroglyoxaline, 1,3-di- $\alpha$ -naphthyltetrahydroglyoxaline, 1,3-diphenyl-2-propyltetrahydroglyoxaline, 1,3-di- $p$ -tolyl-2-phenyltetrahydroglyoxaline, 1,3-diphenyl-2-propenyltetrahydroglyoxaline, 1,3-di- $p$ -tolyl-2-methyltetrahydroglyoxaline, 1-phenyl-3-xylyl-2-thiotetrahydroglyoxaline, and 1,3-di- $\beta$ -naphthyl-2-phenyl-4-methyltetrahydroglyoxaline.

**Rubber compositions.** Albert E. Bond. Brit. 382,709, Nov. 3, 1932. Decorative compns., particularly for laying *in situ* for floorings, etc., are made by incorporating pieces of colored stone, vulcanized rubber, metal, etc., in a paste of rubber latex and filler, e. g., china clay, asbestos powder,  $Al_2O_3$ ,  $Ca(OH)_2$ , fine sand, hydraulic cement. In examples, latex of 70, 60 and 40% concns. is mixed in the presence of a casein base cold  $H_2O$  glue with vulcanizing materials, including ultra-accelerators, and fillers and the paste is mixed with the pieces, the compn. being spread, e. g., by a trowel, allowed to set and dry and the surface then ground or polished. The paste may include C black, pigments, dyes and an anti-agar. In 382,750, Nov. 3, 1932, the pieces are pressed into the spread paste.

**Rubber compositions.** Dunlop Rubber Co. Ltd. and Douglas Frank Twiss. Brit. 390,531, Apr. 7, 1933. Plasticizers, softeners, anti-agers and accelerators that are easily fusible solids or adhesive semi-solids or liquids are incorporated in rubber to form mother stocks by contacting them, in the proportions desired in the finished article, in an easily flowable condition with rubber, preferably in thin sheet form, for a time at a raised temp. by pouring, stirring, spreading or spraying. The mixt. may be given a subsequent milling. In a typical example 10 lb. pale crepe in thin sheet form is heated 15 min. to 60° and 10 lb. stearic acid at 110° added slowly. The hot acid is rapidly absorbed to give a dough which is kept at 90–100° for 1–2 hrs. and then cooled to 35–40° and rolled out in sheet form. In 390,532 similar materials are incorporated by forming them into emulsions or solutions in org. solvents that may themselves be plasticizers, softeners, etc., and contacting with rubber, preferably in thin sheet form. Examples are given.

**Rubber compositions.** Dunlop Rubber Co. Ltd., Douglas F. Twiss and Frederick A. Jones. Brit. 394,007, June 19, 1933. The mix contains, *inter alia*, a basic ingredient or mixt. of ingredients, e. g., accelerators, anti-oxidants, plasticizers or activators, at least 1 of which is basic, together with an aliphatic acid or acidic substance which decomposes with partial or complete loss of acidity at vulcanizing temps. The acid, e. g., malonic, oxalic or others contg. the grouping  $-COCH_2COOH$  or  $-COCOOH$ , may be used as normal or acid salt with 1 of the ingredients. In examples diphenylguanidine malonate, diphenylguanidine H malonate and diphenylguanidine H oxalate are used.

**Rubber compositions.** Dunlop Rubber Co. Ltd., Douglas F. Twiss and Frederick A. Jones. Brit. 394,754, July 6, 1933. An acid salt (or such a mixt. of the acid and base as to form an acid salt) of (substituted)  $NH_4$ , including urea and thiourea, is included as an ingredient in a vulcanizable rubber mix. The salt decomposes with evolution of  $NH_3$  or amine at or near the vulcanization temp. and the acid itself, e. g., malonic, may also decompose with partial or complete loss of acidity. Such ingredients have a "delayed action" effect on vulcaniza-

tion. The base may be  $\text{NH}_3$ , alkylammonium, polymethylene ammonium, urea, alkylurea, thiourea or alkylthiourea and the acid citric, oxalic, tartaric, sebacic, adipic,  $\text{H}_2\text{SO}_4$ ,  $\text{H}_3\text{PO}_4$ , and malonic.

**Rubber compositions.** Dunlop Rubber Co. Ltd., Douglas F. Twiss and Frederick A. Jones. Brit. 395,109, July 18, 1933. Org. acids having 1 or more OH or COOH groups in addn. to the characteristic COOH group present, admixed with or in combination with fluid or relatively easily fusible substances, are added to a vulcanizable rubber mix. The acids include lactic, tartaric, citric, oxalic, malonic, succinic, sebacic, adipic and salicylic. The fluid, etc., substances include glycerol, glycol, triethanolamine,  $\text{PhNH}_2$ , and its homologs,  $\text{Ph}_2\text{NH}$ , the naphthylamines and their derivs.

**Rubber coating compositions.** Giacomo Galimberti and Giuseppe Peverelli. Brit. 302,707, May 25, 1933. An emulsion consists of rubber latex, a drying oil, which may be mixed with resin or gum, or resin, an agglutinate, e. g., casein or gelatin, and  $\text{CH}_2\text{O}$  or a homolog thereof. It may be applied to wood or metal as an elec. insulating material or used for coating or varnishing fabrics or natural leather. In an example fabric is coated several times with a paste of macerated rubber and with white lead, coloring matter or artificial colors pptd. on white lead, china clay or  $\text{BaSO}_4$  and is then further coated with the above compn., stamped or printed with a design and vulcanized in the cold with S chloride in a solvent, e. g.,  $\text{C}_6\text{H}_6$ ,  $\text{CS}_2$ , benzene,  $\text{CCl}_4$ , xylene.

**Preserving rubber compositions.** Archie Reed Kemp and John H. Ingmanson (to Electrical Research Products, Inc.). Brit. 391,510, May 4, 1933. Thermoplastic, unvulcanized insulating compns. suitable for deep-sea cables, contg. rubber, gutta-percha, balata and a plasticizer, e. g., wax, are preserved by adding a small amt. of a substituted amine, e. g., phenyl-2-naphthylamine, aldol-1-naphthylamine (Age-Rite Resin), sym. di-2-naphthyl- $\beta$ -phenylenediamine (Age Rite White), diphenyl- $\beta$ -phenylenediamine (Stabilite), acetaldehyde-ethylcne-diamine (V. G. R.), phenyl-1-naphthylamine. Other antioxidants, conferring inferior elec. properties, but suitable for use in the air are a mixt. of org. bases and 2-naphthol (Allisan) and diaminodiphenylamine (Aynon).

**Preserving rubber.** I. G. Farbenind A. G. Brit. 394,603, June 30, 1933. The aging of natural rubber and artificial rubber-like masses is retarded by adding to the mix compds. of the constitution  $\text{R}'\text{N}(\text{R})\text{N}(\text{CSH})$  or

$(\text{R}'\text{N}(\text{R})\text{N}(\text{CS}))_2$ , in which R is a (substituted) arylene radical and R' is H or a (substituted) hydrocarbon radical.

Radical R' is H or a (substituted) hydrocarbon radical. They are obtained by the action of  $\text{CS}_2$  on *o*-arylenediamines, naphthalene-*peri*-diamines or *o*-semidines. The prepn. is carried out as described in *Gazz. chim. ital.* 23, 205-300 (1893); also cf. Franz Sachs (C. A. 3, 1982). The disulfides are obtained by the oxidation of the monosulfides with  $\text{H}_2\text{O}_2$ .

**Retarding deterioration of rubber.** Louis H. Howland (to Naugatuck Chemical Co.). U. S. 1,930,051, Oct. 10, 1933. Rubber compns. are admixed with a compd. such as tetraaminodimethyltriphenylmethane or the like.

**Preservatives for natural or synthetic rubber.** I. G. Farbenind. A.-G. (Ludwig Ortner, Max Bogemann, and Theodor Weigel, inventors). Ger. 578,672, June 16, 1933. Addn. to 565,090 (C. A. 27, 1233). Use is made of compds. of the formula given in Ger. 565,090, except that the OH or alkoxy group is replaced by an  $\text{NH}_2$  group. Among the compds. specified are 4,4'-diaminodiphenylmethylethane and 1,1-di( $\beta$ -aminophenyl)cyclohexane. The use of unsubstituted diaminodiphenylmethane is disclaimed.

**Synthetic rubber-like composition.** Waldo L. Seimon (to B. F. Goodrich Co.). U. S. 1,920,453, Oct. 10, 1933. An insol. polymerized vinyl halide such as polymerized vinyl chloride is dissolved at an elevated temp. in a compn., such as a mixt. of *o*-nitrodiphenyl ether, dinitro-

benzene and dinitrotoluene, which will serve as a solvent for the polymerized vinyl halide only when heated, in such proportions as to form a stiff, resilient gel at ordinary temps., and the compn. is caused to gel by cooling it. The resulting product is suitable for coatings, insulation, etc.

**Synthetic rubber goods.** R. I. du Pont de Nemours & Co. Brit. 393,172, June 1, 1933. Addn. to 387,340 (C. A. 27, 4717). Articles are made by forming a predet. shape of a dispersion of a 2-halo-1,3-butadiene polymer and simultaneously or subsequently coagulating, without necessarily including S or S compds. and subsequent vulcanization. The dispersions are prep'd. as in 387,340. The dispersions may also contain 2,3-dichloro-1,3-butadiene, e. g., 0.2-5%, salts of glyptal resins, antioxidants, compounding ingredients or natural or vulcanized rubber latex or other synthetic rubber latices. Methods described include extrusion, dipping and electrodeposition. In an example a dispersion in 400 g.  $\text{H}_2\text{O}$  of 2-chloro-1,3-butadiene 400, Na oleate 16,  $\text{NH}_4\text{OH}$  16 and phenyl- $\beta$ -naphthylamine 4 g. is treated with  $\text{NH}_4\text{Cl}$  2.5 and  $\text{NaOH}$  2 g. in a vol. of  $\text{H}_2\text{O}$  equal to that of the latex. It is then electrolyzed with a small Zn plate as cathode and a Zn anode of the size and shape of the article required, the c. d. being 1 millamp. per sq. cm.

**Rubber dispersions.** Dunlop Rubber Co. Ltd., The Anode Rubber Co. Ltd., Douglas F. Twiss and Wm. McCowan Brit. 301,077, June 22, 1933. In prep. compns. contg. rubber and a  $\text{H}_2\text{O}$ -sol. soap as the continuous phase the rubber, preferably premasticated and compounded, is heated to a relatively high temp., e. g., 130° upwards, either alone or in presence of a high-boiling org. liquid, e. g., suitable petroleum fractions, oleic acid or a mixt. thereof. When the rubber is premasticated the addn. of a small amt. of an acidic substance, e. g.,  $\text{Br}_2/\text{OH}$ , toward the end of the mastication aids softening of the rubber.

**Aqueous dispersions of rubber.** Lester Kirschbraun (to Plintkote Corp.). U. S. 1,929,499, Oct. 10, 1933. A mass of rubber material such as crude rubber is subjected to an incipient attenuation, as by the action of a rubber mill, and a colloid such as bentonite and water is added without previous formation as a paste while the mass is undergoing its incipient attenuation. The entire mass is kneaded until the rubber becomes dispersed in the water and the quantity of water used is at all times sufficient to maintain continuously the water as the external phase of the system during the dispersion of the rubber.

**Treatment of rubber dispersions.** Dewey & Almy Chem. Co. Ger. 583,251, Aug. 31, 1933. See Brit. 324,287 (C. A. 24, 3398).

**Rubber articles from dispersions.** Eardley Hazell (to Naugatuck Chemical Co.). U. S. 1,931,002, Oct. 17, 1933. For improving the water- and electrical-resistance of articles made from rubber dispersions, water-sol. substances are removed by electroosmotic passage of liquid such as water through the material. App. is described.

**Molding rubber, etc., articles.** Dunlop Rubber Co. Ltd., The Anode Rubber Co. Ltd., Douglas F. Twiss and Edward A. Murphy. Brit. 387,670, Feb. 7, 1933.

Molded articles, e. g., surgeons' gloves, of, or contg., rubber, etc., and provided with a surface finish ranging from a smooth mat to a coarse granular texture as desired, are made by applying as a coating to formers, molds or molding surfaces the particular type of flocculent or granular ppt. desired, obtained from aq. dispersions or emulsions consisting of, or contg., rubber, gutta-percha, balata or similar vegetable resins occurring naturally or artificially obtained, drying the coatings thereon and contacting the thus produced master former, etc., with aq. emulsions or dispersions of the type above described or solns. of these substances in org. solvents by dipping, spreading, spraying, molding or electrophoresis. The articles may be vulcanized before removal from the master formers, etc. The flocculent or granular ppts. may be obtained by the process of Brit. 360,450 (C. A. 26, 2684).

**Treating surfaces of rubber articles.** Wm. C. Geer.

Brit. 384,911, Dec. 15, 1932. Addn. to 320,427 (C. A. 24, 2689). Hard surfaces are produced on rubber articles, e. g., golf balls, by treatment with a halide of an amphoteric metal dissolved in an org. solvent, the hardness and flexibility of the surface being controlled by selection of solvents of 1 or more of the following types: (a) inert solvents, e. g., ethylene dichloride, (b) solvents forming addn. products with the halide and thus retarding its action, e. g., esters of carboxylic acids and halogen-substituted carboxylic acids, alcs., ketones, phenols and hydrocarbons, (c) solvents that swell the rubber to a limited extent, e. g., PhMe, and (d) substances that accelerate the action of the halide, e. g., stearic acid.

Rubber goods. Dunlop Rubber Co. Ltd., The Anode Rubber Co. Ltd. and Geoffrey Wm. Trobridge. Brit. 383,432, Nov. 17, 1932. Articles of rubber, etc., are produced from aq. dispersions thereof by coating supports or backing strata with a non-coagulating compn. comprising 1 or more polyhydroxy compds. having a slight stabilizing action, e. g., polyhydric alcs. or their derivs. such as glycerol, glycol, diethylene glycol or alkyl ethers of these such as glycol monoethyl ether, in admixt. with 1 or more volatile solvents, e. g., acetone, alc., Et<sub>2</sub>O, then with the aq. dispersions and finally coagulating the deposits, e. g., by heat, with or without coagulating agents and (or) setting and dehydrating means.

Rubber goods. Dunlop Rubber Co. Ltd., The Anode Rubber Co. Ltd., Douglas F. Twiss and William McCowan. Brit. 393,036, June 1, 1933. Articles produced from natural rubber latex are coated with an artificially prepd. aq. dispersion of rubber (substitute) that has been previously heated, either alone or in the presence of a high-boiling liquid, e. g., high-boiling petroleum, oleic or stearic acid, to a relatively high temp., e. g. (over) 140°, to reduce it to a viscous and preferably adhesive state. The dispersion of the treated rubber (substitute) may be mixed with natural latex before application. Alternatively rubber articles may be made directly from mixts. of latex and treated rubber (substitute) dispersion. The assembly of plies of rubber-proofed fabric and the production of a farina finish on rubber-proofed material for rain coats is facilitated by the adhesive properties thus conferred on surfaces obtained by evapn. of latex. Examples are given.

Rubber goods. Benjamin D. Porritt, Thomas R. Dawson, John R. Scott and The Research Association of British Rubber Manufacturers. Brit. 394,730, July 6, 1933. Rubber articles required to resist mech. failure under the influence of liquids that swell vulcanized rubber, e. g., oil hose, packings and valves, include vulcanized rubber having as a constituent a H<sub>2</sub>O-sol. protein, e. g., glue, gelatin, introduced by dissolving the protein in the aq. phase of a rubber dispersion, e. g., latex, removing substantially all the H<sub>2</sub>O from the dispersion and subjecting the mixt. to vulcanization. Vulcanizing agents, accelerators, fillers, etc., may be incorporated.

Rubber products of sponge-like or cellular texture. Edward A. Murphy and Eric W. B. Owen (to Dunlop Rubber Co. Ltd.). U. S. 1,929,603, Oct. 10. An aq. rubber emulsion or dispersion is formed into a mass while in foamed condition and the interior of the mass is caused to set while still in a reversible condition and the setting of a surface of the mass is interrupted in order to prevent formation of a surface skin.

Porous or microporous rubber articles. Dunlop Rubber Co. Ltd. and The Anode Rubber Co. Ltd. Ger. 583,146, Aug. 29, 1933. An aq. rubber dispersion is coagulated in or on molds or surfaces which have been pretreated with a metal soap, preferably Zn stearate. Vulcanization is then effected in known manner under conditions precluding evapn. of liquid from the pores of the coagulate. The pretreatment of the molds or surfaces leads to easily removable products free from surface markings.

Microporous rubber, etc., articles. Dunlop Rubber Co. Ltd., The Anode Rubber Co. Ltd., Evelyn W. Madge

and Albert N. Ward. Brit. 395,022, June 1, 1933. Articles of microporous rubber, etc., which are free from surface markings and easily removable from the mold e. g., hard rubber battery separators, are made by a modification of the known process, in which dispersions are gelled and vulcanized under conditions such that evapn. of the liquid in the pores is prevented, by cooling, preferably sharply, the product part of the way through the vulcanization which is thereafter carried to completion, the articles remaining in the original mold or on the original backing. The process is particularly applicable to the processes of Brit. 346,810 (C. A. 27, 446), 351,937 (C. A. 27, 445), 366,120 (C. A. 27, 2339), 377,751 (C. A. 27, 4130) and 393,023. In 393,023 similar articles are made by a modification of the above-described known process, consisting in treating the mold surfaces prior to introduction of the dispersions with certain non-oily metallic salts of the higher fatty acids, namely those of Zn, Cd, Mg, Al and ferric Fe, preferably Zn stearate. The invention is particularly applicable to the process of 393,022 and to those referred to therein.

Rubber threads, etc. Dunlop Rubber Co. Ltd., The Anode Rubber Co. Ltd., Edward A. Murphy and Robert G. James. Brit. 393,057, June 1, 1933. Threads, tubes, etc., are made by extruding aq. dispersions of rubber, etc., into a coagulating medium which operates partly or entirely under continuous penetrative osmotic action and comprises a concd. soln. of a salt of a weak acid capable of considerable dissociation together with such an amt. of the weak acid that the  $pH$  is 4.0-6.5. The aq. dispersions contain a substance adapted to react with the coagulating medium and which, until it has so reacted, is substantially inert to the dispersions but thereafter is decompd. into a mild coagulant effecting a smooth coagulating action throughout the thickness of the thread. Suitable inactive substances that can be added to the dispersions are NH<sub>4</sub> and ethanolamine soaps of the fatty acids and colophony.

Ornamenting rubber. The B. F. Goodrich Co. Fr. 748,940, July 13, 1930. A decorated rubber article is produced by applying to an unvulcanized rubber base a liquid decorating layer of rubber, which is of lower plasticity at all temps. to which the rubber is subjected during vulcanization than the base. The base layer may be of masticated unvulcanized rubber and the applied pattern of latex, which is dried, the article being then vulcanized.

Attaching rubber to metal. Dunlop Rubber Co. Ltd., Douglas Frank Twiss, John Alex. Wilson and Albert Edw. T. Neale. Brit. 390,932, Apr. 20, 1933. In uniting rubber to a metal surface an intermediate layer is introduced, consisting of, or contg., Cu, Hg, Mn or Fe (preferably ferric) salts of org. acids contg. 1 or more reactive groupings in addn. to the characteristic acid group, e. g., salicylic, thiosalicylic or picric acid. The metal may be coated with the salt or with successive films of the acid and the oxide, hydroxide or amino-hydroxide of the metal or with a film of 1 of the ingredients while the other is applied to the rubber.

Uniting rubber with rigid materials such as steel plates or other metal articles. Owen A. Thompson (to B. F. Goodrich Co.). U. S. 1,981,309, Oct. 17. The materials are united with an intervening layer comprising vulcanizable rubber together with a fusible synthetic resin capable of hardening and becoming infusible when heated, and the assembled materials are heated.

Apparatus for plasticizing rubber. George R. Burrell (to Wingfoot Corp.). U. S. 1,930,736, Oct. 17. Mech. features.

Plastic compositions. Herman L. Grupe and Roy H. Kienle. Brit. 395,217, July 13, 1933. Rubber latex or a rubber dispersion is compounded with an alkyl resin in alk. soln. or dispersion. Vulcanizing agents and other compounding and filling ingredients may be incorporated. If an ammoniacal or alk. soln. of the resin is used the mixt. is coagulated, washed and dried. The products are resistant to mineral oils and hydrocarbons and useful

for gaskets, oil-proof cloth, gasoline gauze diaphragms, wire coatings, etc.

**Resilient, gasoline-resistant rubber stock.** David J. Beaver (to Doherty Research Co.). U. S. 1,930,437, Oct. 10. A compn. formed from rubber, a vulcanizing agent such as S, a soft C black and less than 5% of a softener such as stearic acid is vulcanized and the degree of resilience of the stock after cure is controlled by mixing with the C black used a minor portion of channel black before compounding the C black with the rubber, the relative proportions of the materials being adjusted to form a rubber stock which when vulcanized is gasoline-resistant.

**Rubber-refining machine with rolls of different diameters, etc.** Henry G. Brewster (to Farrel-Birmingham Co.). U. S. 1,930,873, Oct. 17. Mech. features.

**Rubber paving and coverings.** Wee Theang Siew. Brit. 380,828, Sept. 19, 1932. Rubber coverings for roads, floors, roofs, ceilings, etc., are vulcanized *in situ* and consist of 1 or more inner layers of soft rubber and 1 or more outer layers of hard rubber. The foundation is cleaned and sprayed with a cementing soln. consisting of 1 gal. naphtha or benzine and 1 lb. of a mixt. of compn. plantation rubber 24, whitening 12, PbO 16 and S, or its equiv., 1.25 parts. The soft rubber may be plantation rubber 73, ZnO 18, S 6, powd. rosin 2 and CaO 1%. The hard layer(s) may be plantation rubber 44, 36; tread reclaimed rubber 0, 10; ZnO 50, 40; S 3, 5; lime or equiv. 1, 1, coloring matter 2, 0 and C black 0, 10%. The vulcanizing may be effected by the machine of Brit. 380,121 (C. A. 27, 5580).

**Waterproof indelible prints on rubber.** Hermann Beckmann. U. S. 1,930,301, Oct. 10. A waterproof indelible ink is adsorbed in the pores of a cured, colloidal rubber article of reticulate structure having microscopically visible filter-size pores such as in the production of bank notes or documents.

**Halogenated butadienes and butenes.** E. I. du Pont de Nemours & Co. Brit. 395,131, July 13, 1933. Addn. to 387,325 (C. A. 27, 4718). The process of 387,325 is effected by passing gaseous monovinylacetylene into contact with a soln. of H halide at a rate which is varied in accordance with the product desired, a higher rate of flow favoring the production of halobutadienes and a lower rate that of halobutenes.

**Substituted fatty acid amides.** I. G. Farbenind. A. G. (Robert Knoll, inventor). Ger. 582,390, Aug. 14, 1933. Higher fatty acids or their esters, chlorides, amides or imino ethers are condensed by standard processes with primary or secondary aromatic amines substituted by a side chain which contains a tertiary N atom. Alternatively, a side chain contg. a tertiary N atom is introduced in known manner into the condensation products of higher fatty acids or their derivs. with primary or secondary aromatic amines. The products are useful as "assistants" in the rubber industry and as thickening agents for medicines and cosmetics. Examples are given of the prepn. of the *p*-diethylaminoethoxyamides of oleic, palmitic, hydrocaptive and chaulmoogric acids (HCl salts m., resp., 85.7, 108.11, 94.6 and 87.90°); palmityl- and stearyl-*p*-(ethyl)(diethylaminoethyl)aminoanilides (HCl salts m., resp., 81° and 94°); oleyl-*p*-(methyl)(diethylaminoethyl)aminoanilide - HCl; *p*-palmitylamino-benzoic acid diethylaminoethyl ester (HCl salt, m. 116°); oleyl-*N*-*p*-hydroxyphenyl-*N*-diethylaminoethylamido-HCl; and stearyl-7-diethylaminoethoxy-1-naphthylamide-HCl. The following intermediates are described: *p*-diethylaminoethoxyaniline, b<sub>p</sub> 170°; *p*-diethylaminoethylaminophenol, b<sub>p</sub> 172.80°; and 7-diethylaminoethoxy-1-naphthylamine, b<sub>p</sub> 213-7°, m. 66-7°.

**Rubber vulcanization accelerator.** Winfield Scott (to Rubber Service Laboratories Co.). U. S. 1,931,394, Oct. 17. For accelerating vulcanization there is added a small proportion of a compd. obtained by treating about one mol. proportion of a Schiff's base produced by com-

binizing substantially equimol. proportions of an aliphatic amine such as butylamine and an aldehyde series contg. 4 to 10 C atoms such as butyric acid while simultaneously causing the Schiff's base to react with substantially 2 mol. proportions of an aliphatic aldehyde such as butyraldehyde.

**Vulcanizing.** Sidney M. Cadwell (to The Naugatuck Chemical Co.). Brit. 383,679, Nov. 24, 1932. The vulcanization of rubber is controlled to avoid scorching, etc., by incorporating, in addn. to an accelerator, an acidic retarding agent and at any time before or during vulcanization nullifying the retarding effect by treatment with NH<sub>3</sub>. Org. and inorg. acids, acid salts, heavy metal salts of strong acids, acid anhydrides and chlorides, etc., may be used as retarders. Twelve examples are given showing the results with various mixes, including crepe and sprayed rubber.

**Rubber vulcanization.** Harold A. Morton. U. S. 1,929,561, Oct. 10. Pre-vulcanization of compds. contg. rubber, a vulcanizing agent such as S and ZnO together with an "ultra accelerator" such as dimethylammonium dimethyldithiocarbamate is prevented by addn. of compds. such as benzoic acid or a similar compd.

**Rubber vulcanization.** Robert L. Sibley (to Rubber Service Laboratories Co.). U. S. 1,931,396, Oct. 17. In vulcanizing with S, an accelerator is used comprising a reaction product of an org. acid halide such as phthalyl chloride and a mercaptoarylthiazole deriv. of an org. base such as a mercaptobenzothiazole deriv. of (CH<sub>3</sub>)<sub>3</sub>N<sub>4</sub>.

**Rubber vulcanization.** Robert L. Sibley (to Rubber Service Laboratories Co.). Brit. 391,122, Apr. 18, 1933. The vulcanization of rubber is accelerated by adding to the mix a salt of a (substituted) guanidine with an org. acid, e. g., diphenylguanidine benzoate, acetate and phthalate, guanidine acetate and phthalate, in admixt with 1 or more other accelerating compds., e. g., the reaction product of a mercaptoarylthiazole and an aromatic acid halide, the crotonaldehyde deriv. of the reaction product of mercaptobenzothiazole (I) and (CH<sub>3</sub>)<sub>3</sub>N<sub>4</sub>, the AcH deriv. of the reaction product of *p,p'*-diaminodiphenylmethane and I.

**Rubber vulcanization.** Wm. F. Tuley (to The Naugatuck Chemical Co.). Brit. 387,454, Feb. 9, 1933. To avoid pre-vulcanization or scorch, accelerators of the "ultra" or "semiultra" type are used with material which at vulcanizing temp. decomposes to give NH<sub>3</sub> or aliphatic amines that aid acceleration. Such material comprises compds. of the type R'R'NC:ONHR, where R is H or an aliphatic (including aralkyl) hydrocarbon radical, R' and R'' are H or similar or dissimilar aliphatic or aromatic hydrocarbon radicals, and includes urea, mono- and disubstituted ureas. Examples of acidic derivs. are complex salts of urea and its homologs with ZnCl<sub>2</sub> or amide, org. or inorg. acid salts such as urea oxalate, urea-HCl, etc. In examples urea is used in conjunction with mercaptobenzothiazole, 2,4-dinitrophenyl benzothiazyl sulfide, tetramethylthiuram monosulfide, etc.

**Vulcanizing rubber.** R. T. Vanderbilt Co., Inc. Ger. 583,278, Sept. 6, 1933. See U. S. 1,875,997 (C. A. 27, 2198).

**Vulcanized products from natural or synthetic rubber.** Hermann Mark and Heinrich Hopff (to I. G. Farbenind. A.-G.). U. S. 1,929,373, Oct. 3. For the production of products of good resistance to attrition, rubber or a polymeric material derived from diolefins is treated, at temps. up to 100° or lower, in the presence of an inert solvent such as C<sub>6</sub>H<sub>6</sub> with an "org.-inorg." oxonium compd. such as may be formed from AlCl<sub>3</sub> and phthalyl chloride.

**Device for vulcanizing rubber soles to the uppers.** Bata Akciova Spolenost. Brit. 394,564, June 29, 1933.

**Apparatus and method for molding and vulcanizing gas-filled hollow articles of rubber, etc., e. g., tennis balls.** Dunlop Rubber Co. Ltd. Brit. 394,595, June 29, 1933.

# CHEMICAL ABSTRACTS

Vol. 28

JANUARY 20, 1934

No. 2

## 1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

- Filtering device. E. B. Kester. *Ind. Eng. Chem., Anal. Ed.* 5, 422(1933).—A Bakelite or soft rubber plunger is fitted into a glass test tube. The filtrate can escape and the ppt. or solid is sepd. out. J. L. E.
- Automatic pipet washer. Ellen Howell and Fannie Mac Frank. *Am. J. Pub. Health* 23, 1186(1933). J. A. K.
- A convenient weighing buret. Jacob Cornog and Robert Cornog. *Ind. Eng. Chem., Anal. Ed.* 5, 408(1933). G. G.
- Buret with reservoir for series titrations. M. Chatron. *Bull. soc. chim. biol.* 15, 1154 5(1933).—A 1-l. dropping funnel is mounted on top of a buret. L. E. Gilson
- Stirring rod with fritted glass disk. John E. S. Han. *Ind. Eng. Chem., Anal. Ed.* 5, 421(1933).—A fritted glass disk sealed on the end facilitates removal of gaseous products. J. L. E.
- Mercury seal for stirrers. D. T. Rogers. *J. Am. Chem. Soc.* 55, 4901(1933).—A Hg seal made of Allegheny metal No. 22 or soft steel coated with paint is good for speeds of 1000 r. p. m. J. L. E.
- Continuous liquid extractor. Abraham Mazur, Robert Rosenthal and Benjamin Harrow. *Ind. Eng. Chem., Anal. Ed.* 5, 419(1933).—An extractor is devised for solvents having a lower sp. gr. than the liquid to be extd. The solvent condenses and is passed upward through the liquid being extd. and thence into the reboiler. J. L. E.
- An automatic cryostat. Angus E. Cameron. *Rev. Sci. Instruments* 4, 610-11(1933).—An app. to hold any temp. from 0° to -70° within 0.1° by forcing cold liquid from a reservoir into the thermostat and automatically returning an equal vol. is described with 1 cut. J. H. M.
- Apparatus for filling large closed-end manometers. Angus E. Cameron. *Ind. Eng. Chem., Anal. Ed.* 5, 419(1933).—A diffusion pump in which Hg is distd. into the manometer tube is described. J. L. E.
- Micropycnometer for the determination of differences in the isotopic ratio of water. E. S. Gillfillan and M. Polanyi. *Z. physik. Chem.* A166, 254-6(1933).—The pycnometer is made of a capillary 6 mm. long and 1 mm. wide with one end closed. The other end has an opening 0.02 mm. wide. The closed end is fitted with a bulb of such size that the pycnometer just floats at 0° in ordinary H<sub>2</sub>O. By varying the pressure on the bulb in H<sub>2</sub>O of different ds. it is found that a change of external pressure of 1 cm. Hg corresponds to a change of d. of 10<sup>-4</sup> mg. With a total variation of 1 atm. and if one reads the pressure to 1 mm., differences in d. between 10<sup>-6</sup> and 10<sup>-8</sup> mg. may be detected. An error in the result for ordinary H<sub>2</sub>O found in successive readings requires that the app. be re-calibrated for each measurement. The cause of this error has not yet been detd. G. M. Murphy
- The Höppler viscometer. C. Kaiser. *Petroleum Z.* 29, No. 36, *Motorentrieb und Maschinen-Schmierung* 6, No. 9, 5-6(1933).—The instrument, operating on the basis of the time of fall of balls of various sizes through the fluid under investigation, is discussed. It is more accurate, has a much wider effective range (0.2-220,800 centipoises) than the viscometers now ordinarily used, and the results are easily converted into C. G. S. units. Detns. on the same sample of fluid at various temps. can be quickly executed. I. M. Levine
- How to select ammonia compressors. W. R. Kit-miller. *Power* 77, 565-7(1933).—K. discusses vertical, horizontal, rotary, compound and dual-effect compressors and their applications. Alden H. Emery
- Gas purification in the chemical plant. H. W. Gonell. *Chem. Fabrik* 1933, 479-83, 489-91.—Dust chambers, cyclones, cloth filters, stationary and revolving washers, electrostatic filters, oil-moistened metal filters, Kestner turbo-atomizers and Theisen disintegrators are discussed with 16 cuts and many references. J. H. Moore
- Mercury switches for conductivity experiments. Eugene W. Blank. *J. Chem. Education* 10, 751(1933). E. H.
- Modified design for mercury bulb of thermostat. G. B. Heisig and Angus F. Cameron. *Ing. Eng. Chem., Anal. Ed.* 5, 420(1933).—A modification of the present large-bulb thermostat is made by sealing 2 concentric tubes together at one end, this making a hollow cylinder of Hg; also provision is made for circulating liquid through inner space. J. L. E.
- A simple sensitive thermostat regulator. Chas. E. Woodworth. *Science* 78, 535-6(1933). E. H.
- Evaporator construction (Vorkauf) 13.
- Apparatus for carrying out chemical reactions between gases and liquids in flow, e. g., for preparing monochlorohydrins from gaseous unsaturated hydrocarbons and hypochlorous acid. Paul Letourneur. *Brit.* 396,744, July 31, 1933.
- Hydrometer float. Howard E. Christie and Kibbey W. Couse. U. S. 1,935,564, Nov. 14. Structural details.
- Temperature-regulating apparatus. George E. Hulse (to Safety Car Heating & Lighting Co.). U. S. 1,932,408, Oct. 31. Various mech. and electrical details are described.
- Mercury-column thermometer. Logan Eisele. U. S. 1,932,578, Oct. 31. Structural details.
- Viscometer. Wilhelm Valentiner. *Ger.* 577,578, June 1, 1933.
- Filters. Eugen Haas. *Brit.* 395,871, July 27, 1933.
- Filters. Svenska Ackumulator Aktiebolaget Jungner and Thor F. Mandahl. *Brit.* 396,840, Aug. 17, 1933.
- Filters. Enzinger-Union-Werke A.-G. *Brit.* 396,255, Aug. 3, 1933. The filtering media of beer and other filters are cleansed mechanically outside the filter and, after being charged into the filter, sterilized by the passage or circulation of a heated or other disinfecting agent. App. is described.
- Laboratory filter with a perforated porcelain bottom. Fritz Müller. *Ger.* 577,627, June 2, 1933.
- Suction drum cell filter. Maschinenfabrik Baum A.-G. and Wilh. Hocheisel. *Ger.* 577,767, June 3, 1933.
- Air filters. Amal Ltd. and Clement Brown. *Brit.* 395,498, July 20, 1933.
- Dust filters. The New Shariston Collieries Co. and Philip D. Barker. *Brit.* 396,066, July 17, 1933.
- Filter with granular filtering material. Carbo-Norit-Union Verwaltungsges. m. b. H. (Eduard Siebert, inventor). *Ger.* 586,064, Oct. 16, 1933.
- Device for filtering grinding solutions (such as used in grinding metals) through horsehair filters or the like. Rudolph A. Walters and Niels A. Sorenson. U. S. 1,932,996, Oct. 31. Structural details.

- Filters and strainers.** Wm. R. Beldam. Brit. 396,156, Aug. 3, 1933.
- Filter-presses.** Kautzinger-Union-Werke A.-G. Brit. 396,612, Aug. 10, 1933.
- Filter plate for filter press.** Firma Louis Herrmann. Ger. 586,243, Oct. 19, 1933.
- Apparatus for separating materials of different densities by means of a fluid medium.** Thomas Chance. Brit. 396,558, Aug. 10, 1933.
- Air separators suitable for grading solid materials.** Thomas J. Sturtevant (to Sturtevant Mill Co.). U. S. 1,933,604-5-6, Nov. 7. Structural, mech. and operative details.
- Centrifugal apparatus suitable for separating solids from liquids.** Leo D. Jones (to Sharples Specialty Co.). U. S. 1,931,496, Oct. 24. Various structural, mech. and operative details are described.
- Separator for classifying a mixture of solids in a liquid, e. g., ore pulp, or for separating solids from liquids.** Donald MacLean. Brit. 396,233, Aug. 3, 1933.
- Centrifugal apparatus suitable for separating ore pulps, etc.** Harrison S. Coc. U. S. 1,931,406, Nov. 7. Various structural, mech. and operative details are described.
- Centrifugal separation of materials such as starch and gluten, etc.** Albert Peltzer and Albert Peltzer, Jr. (to Merco Centrifugal Separator Co., Ltd.). U. S. 1,933,119, Oct. 31. Mech. features.
- Sieves.** John J. Mayor. Brit. 396,525, Aug. 10, 1933.
- Plansifter sieves.** Henry Simon Ltd. and Charles Ledger. Brit. 395,850, July 27, 1933.
- Pan-conveyor sifting apparatus.** The Fife Coal Co. Ltd. and John Paton. Brit. 396,602, Aug. 10, 1933.
- Metal funnel with a foldable discharge stem (which may be formed of thin metal).** Rufus B. Lillard. U. S. 1,935,324, Nov. 14. The discharge stem may be bent on itself to stop discharge when desired.
- Spray evaporators.** Martinus J. Stam. Brit. 396,579, Aug. 10, 1933.
- Multiple-effect evaporators, applicable to the concentration of milk, whey, gelatin, glue, lactic acid, fruit juices, vitamins, sugar, blood, etc.** Alfred R. Jahn. Brit. 395,957, July 27, 1933.
- Apparatus for evaporating liquids by circulation.** Escher Wyss Maschinenfabriken A.-G. Swiss 160,164, Apr. 17, 1933.
- Apparatus for evaporating solutions to dryness.** Theodor Lichtenberg. Ger. 577,685, June 2, 1933.
- Drying devices for separated coarse material in ball or tube mills.** Fried. Krupp Grusonwerk A.-G. Brit. 395,912, July 27, 1933. In a ball mill in which an air current carries the ground material to a sifter where the coarse material is sep'd. and conducted back to the mill drum the coarse material is dried previous to its introduction into the drum.
- Tubular drier.** Niedersaatz-Kohlenwerke. Ger. 576,155, May 8, 1933. Addn. to 555,678 (C. A. 26, 6104).
- Blower for tube driers.** Maschinenfabrik Buckau. R. Wolf. A.-G. Ger. 577,680, June 2, 1933.
- Trough drier with rotating hot gas drum.** Buttnr-Werke A.-G. Ger. 577,776, June 3, 1933.
- Vacuum drier for pasty materials.** Reckitt & Sons. Ger. 577,601, June 3, 1933.
- Vacuum drum drier suitable for drying milk, etc.** Henry D. Miles and Duncan B. Montgomery (to Buffalo Foundry and Machine Co.). U. S. 1,933,819, Nov. 7. Various structural, mech. and operative details are described.
- Apparatus for drying articles in plate form, e. g., plates of fibrous material.** Eugen Siempelkamp and Ewald Siempelkamp (trading as G. Siempelkamp & Co.). Brit. 396,621, Aug. 10, 1933.
- Gas-washing apparatus.** Hermann Blehtreu and John B. Eberlein (to Freyn Engineering Co.). U. S. 1,933,699, Nov. 7. Various structural and operative details of an app. with spray nozzles are given.
- Apparatus for washing gases.** Appareils et évaporateurs Kestner. Fr. 750,049, Aug. 3, 1933.
- Apparatus for removing liquid particles from gases under compression.** Ammonia Casale S. A. Swiss 162,138, Aug. 10, 1933.
- Scrubber washing or purifying gases with liquids.** London Power Co. Ltd. and Standen L. Pearce. Brit. 396,489, Aug. 10, 1933.
- Centrifugal gas-cleaner for use with an internal-combustion engine or for other purposes.** Andrew Swan. Brit. 396,157, Aug. 3, 1933.
- Device for testing gases.** Frank O. Barralet and Colbert E. Richards. Brit. 396,672, Aug. 10, 1933.
- Rotary gas compressors.** Serge R. Seilliere. Brit. 396,425, Aug. 1, 1933.
- Gas-pressure regulator.** Walter I. Thrall (to Reliance Regulator Corp.). U. S. 1,931,777, Oct. 24. Structural and mech. details.
- Gas valve suitable for stopping gas flow when a flame is extinguished.** Friedrich Trudwig. U. S. 1,934,020, Nov. 7. Mech. features.
- Apparatus for taking samples of gas such as that from a main at timed intervals.** Gaylord H. Halvorson. U. S. 1,932,582, Oct. 31. Various structural and operative details are described.
- Hollow condensing or refrigerating tower suitable for treating acid gases.** Ottmar Conradty. U. S. 1,932,954, Oct. 31. A tower is formed of hollow cylindrical sections of carbonaceous material such as coal or graphite.
- Apparatus for heating liquids at high pressure to high temperatures, particularly for use in cracking and distilling oil and in distilling glycerol and acids.** Robert A. Carleton. Brit. 395,709, July 12, 1933.
- Device for treating liquids with a volatile extraction agent.** Einar Langfeldt and Ragnvald Hellerud. Ger. 577,626, June 2, 1933.
- Photoelectric cells.** N. V. Philips' Gloeilampenfabrieken. Brit. 396,348, Aug. 3, 1933. In the prep'n. of an alkali metal electrode excess alkali metal, e. g., Cs, is removed by providing 1 or more metals in the cell, outside the photoelectric electrode, capable of forming an alloy with said alkali metal at below 150°. The metals may be Zn, Cd, Hg, Sn, Pb or Ge.
- White luminous effects in electrified neon tubes.** Rudolph de Lamprecht (to Cold White Light Inc.). U. S. 1,931,529, Oct. 24. Tubes are filled with Ne with the addition of a decolorizing gas produced by adding H<sub>2</sub>SO<sub>4</sub> to ZnO in small regular increments.
- X-ray tube.** Albert Bouwers (to N. V. Philips' Gloeilampenfabrieken). U. S. 1,933,005, Oct. 31.
- Röntgen-ray apparatus.** N. V. Philips' Gloeilampenfabrieken. Brit. 396,803, Aug. 14, 1933.
- Cathode-ray and Röntgen-ray tubes.** Telefunken Gesellschaft für drahtlose Telegraphie m. b. H. Brit. 395,882, July 27, 1933.
- Cathode-ray tubes.** Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 395,660, July 20, 1933. In a gas-filled tube an electrode, such as a disk with a central aperture, is disposed between a Wehnelt cylinder and a thermionic cathode forming a coned. source of electrons. The cathode consists of a Ni tube contg. a heating wire sep'd. by a partition from a small cylinder coated with BaO, the end of the tube being closed by a cap having an aperture smaller than that in the disk. The disk is connected directly with the anode.
- Cathode-ray tubes.** Wm. Richard Bullimore and Leslie H. Bedford. Brit. 396,422, July 31, 1933.
- Discharge apparatus.** Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 396,928, Aug. 17, 1933. In a dependent arc discharge device, e. g., a rectifier, a magnetic field of 10-100 gauss is applied to the discharge space at right angles to the electrostatic field between a directly or indirectly heated cathode and an anode to cause the efficiency factor to have a max. value. The device may contain Hg.
- Discharge apparatus.** Ted E. Foulke (to The British

Thomson-Houston Co. Ltd.). Brit. 397,107, Aug. 8, 1933. A cathode-glow device has at least 1 electrode consisting of a foundation, *e. g.*, of Ni, having a portion of its surface to which the glow is to be confined coated with an activating substance having a work function lower than that of Al, *e. g.*, Ba, mixed with BaO, while the remainder is coated with material having a higher work function than that of the activating substance, *e. g.*, Al, Al<sub>2</sub>O<sub>3</sub>, Sb, Se, CuO.

**Electric discharge device.** Frederick Barton (to General Elec. Co.). U. S. 1,934,477, Nov. 7. A device is described which comprises an envelope contg. a cathode, an anode and a control member formed entirely of metal and coated with Ag, Cu or Pb which may be carried on an underlying metal such as Mo.

**Electric discharge tubes.** N. V. Philips' Gloeilampenfabrieken. Fr. 41,744, Mar. 29, 1933. Addn. to 729,219.

**Gas-discharge tubes for use with electric out-outs** Francis T. Jenkins. Brit. 397,108, Aug. 14, 1933.

**Discharge tubes operating without appreciable gas ionization.** C. H. F. Müller A.-G. Brit. 396,930, Aug. 17, 1933.

**Discharge tubes containing gas or mercury vapor.** Eugene A. Giard (to Igranic Electric Co. Ltd.). Brit. 396,998, Aug. 17, 1933.

**Gaseous discharge tubes.** Hans J. Spanner and Carl J. H. R. v. Wedel (to Electrons, Inc.). U. S. 1,934,830, Nov. 14. An incandescible electron-emissive cathode subject to ionic bombardment comprises at least on its surface a double metal compd. such as a Ba-Ni nitride or the like which is non-vaporizable at temps. at which the cathode has an emissivity substantially equal to the emissivity of BaO at 650°.

**Luminous gas discharge tubes.** Unecol Ltd. and Leonard H. Soundy. Brit. 395,804, July 27, 1933.

**Apparatus for controlling the vacuum in vacuum discharge apparatus.** Walter Dallenbach. U. S. 1,933,097, Oct. 31.

**Introducing active metal into evacuated electric discharge devices.** Jan H. de Boer, Johan L. H. Jonker and Karel M. van Gessel (to Radio Corp. of America). U. S. 1,931,647, Oct. 24. A mixt. of active metal (such as Ba from Ba azide) together with a refractory insulating material such as MgO or Zr oxide sufficient in amount to render the mixt. electrically insulating is placed in an evacuated elec. discharge device and heated to vaporize some of the metal.

**Thermionic discharge tubes.** Compagnie française pour l'exploitation des procédés Thomson-Houston. Fr. 41,505, Jan. 28, 1933. Addn. to 723,932. The cathodes are formed of piled disks with emissive substance.

**Thermionic discharge tubes.** Compagnie française pour l'exploitation des procédés Thomson-Houston. Fr. 41,679, Mar. 10, 1933. Addn. to 723,932.

**Thermionic cathodes.** Allgemeine Elektrizitäts-Gesellschaft (to International General Electric Co., Inc.). Brit. 395,529, July 20, 1933. A cathode, particularly for Braun and Röntgen-ray tubes, consists of a pin-shaped electron-emitting portion which is heated by conduction and (or) radiation from another non-emitting portion and has a cross-section corresponding to the desired shape of the fluorescent speck. The pin may be tipped with alk.-earth oxide, or the tip may be hollow and filled with the oxide.

**Thermionic cathodes.** Siegmund Loewe. Brit. 395,537, July 20, 1933. In mfg. highly emissive cathodes for rectifiers, amplifiers or oscillation generators a superficially oxidized cathode core, *e. g.*, a W wire, is introduced into an atm. of a highly emissive metal, *e. g.*, Ba, in a vacuum furnace and heated to a temp. to react with the vapor to form a coating of BaO thereon, after which excess vapor is removed by pumping or condensing and a part of the wire is mounted as a cathode in a thermionic tube, heated to degasify it and convert any residual hydroxide or carbonate into the pure metal oxide and finally provided with a coating of highly emissive metal which is evapd. within the tube. The latter metal may be the same as that vaporized to form the oxide but

preferably consists of a light metal having a higher evapn. point. The filament material, preferably W, may be coated initially with W oxide by introducing a loosely wound coil thereof into a furnace contg. H with a proportion of H<sub>2</sub>O.

**Thermionic cathodes.** Wm. F. Winter, Jr. (to The British Thomson-Houston Co. Ltd.). Brit. 395,794, July 27, 1933. A cathode comprises a heating member, a metal cylinder having radial metallic members, *e. g.*, of Ni, mounted thereon and layers of emissive material, *e. g.*, a Ba compd., filling the spaces between the radial members (disks).

**Thermionic cathodes.** Radioaktiengesellschaft D. S. Loewe and Ernst Waldschmidt. Brit. 395,862, July 27, 1933. Highly emissive cathodes are made by producing on a W wire a coating of the higher oxides WO<sub>3</sub> and W<sub>2</sub>O<sub>5</sub>, reducing these to WO<sub>3</sub> and vaporizing an alk.-earth metal, *e. g.*, Ba, on the WO<sub>3</sub>. The W wire is initially cleaned by passing through a furnace at 400-500° to oxidize the surface and burn off org. matter and then passing through a molten alk. mass, *e. g.*, NaOH at 300-400°, to remove the oxide and impurities. Prior to passing through the mass it may also be passed through a soln. of bichromate in concd. H<sub>2</sub>SO<sub>4</sub> to make org. impurities, *e. g.*, aromatic oils, sol. in H<sub>2</sub>O and then through H<sub>2</sub>O baths. The cleaned wire is passed through a furnace at 700° to form the higher oxides and then through a reducing furnace, through which a preheated mixt. of H and steam passes, to form the WO<sub>3</sub>. App. is described.

**Thermionic cathodes.** A-C Spark Plug Co. Brit. 396,514, Aug. 10, 1933. Electron-emitting electrodes for vacuum or gas-filled tubes comprise a homogeneous alloy of Ni, Cr and Ba, Sr and (or) Ca, the alloy being oxidized on its surface. It may contain 0.01-0.2% Ba and 0.5-10% Cr, and 1.5-2% Mn or other deoxidizing metal, *e. g.*, Ca, may be added to facilitate rolling and drawing. The electrode, which is oxidized by heating in air, O or CO<sub>2</sub>, is finally activated by heating to 1000-1500° in a vacuum or inert gas, *e. g.*, A, He.

**Thermionic cathodes.** Bernhard Erber and Alfred Schwitzer (trading as Gustav Ganz & Co.). Brit. 396,905, Aug. 17, 1933. Addn. to 371,419 (C. A. 27, 2350).

**Thermionic cathodes.** The M-O Valve Co. Ltd., Mark Benjamin, Charles E. Ransley and Colin J. Smithells. Brit. 397,132, Aug. 16, 1933. A core for an oxide-coated cathode contains not more than 5% of Ti and (or) Al. When Al is present, the core contains not substantially less than 2% thereof. The main constituent is preferably Ni but may be Ni alloys, Fe or Pt. Ti may be introduced as Ti-Ti, the final alloy contg. Fe and Ti.

**Thermionic valves.** Bernhard Erber and Alfred Schwitzer (trading as Gustav Ganz & Co.). Brit. 396,527, Aug. 10, 1933. Addn. to 371,419 (C. A. 27, 2350).

**Thermionic valves.** Arcturus Radio Tube Co. Brit. 396,799, Aug. 14, 1933.

**Thermionic valves.** Rogers Radio Tubes Ltd. Brit. 397,126, Aug. 15, 1933.

**Thermionic valves.** Julius Pintsch A.-G. Brit. 397,216, Aug. 24, 1933.

**Thermionic valves for wireless receiving apparatus.** Frank M. Hills and John S. Faulkner. Brit. 396,436, July 27, 1933.

**Thermionic wave amplifiers.** Radioaktiengesellschaft D. S. Loewe and Paul Kapteyn. Brit. 395,823, July 27, 1933. Addn. to 395,050 (C. A. 28, 7).

**Thermostatic regulation for electric discharge apparatus.** Compagnie française pour l'exploitation des procédés Thomson-Houston. Fr. 41,726, Mar. 29, 1933. Addn. to 728,612.

**Rotary smelting furnace operated by coal dust.** Gebrüder Buhler. Swiss 101,900, Aug. 1, 1933.

**Gas-fired furnace using compressed gas.** Indugas Industrie- und Gasofen-Bauges. m. b. H. and Christian Pfeil. Ger. 585,437, Oct. 13, 1933, and 586,099, Oct. 16, 1933.

**Vertical retort furnaces.** Drakes Ltd. and Marcellus Thompson. Brit. 396,122, Aug. 3, 1933.

- Rotary kilns.** Mikael Vogel-Jorgensen. Brit. 395,729, July 21, 1933.
- Tunnel kilns.** Gibbons Brothers Ltd. and Wm. E. Gibbons. Brit. 395,983, July 27, 1933.
- Furnace operation.** Willibald Trinks (to Libbey-Owens-Ford Glass Co.). U. S. 1,933,571, Nov. 7. In the operation of furnaces such as those for glass manuf., products of combustion are taken off and cooled, mixed with gaseous fuel, the gaseous fuel is cracked, and the mixt. is fed to the furnace. App. is described.
- Megass feeder for a furnace.** Charles D. C. Mathews. Brit. 396,030, July 21, 1933.
- Apparatus for heating liquids for use in process plants.** Babcock & Wilcox Ltd. and Christopher H. Davy. Brit. 396,470, Aug. 10, 1933.
- Safety devices for gas-heated appliances.** Robert Bosch A.-G. Brit. 384,200, Dec. 1, 1932, and 395,964, July 27, 1933, addn. to 384,200.
- Temperature-control device for oil burners.** Elliott D. Harrington (to General Elec. Co.). U. S. 1,932,269, Oct. 24. Various structural and operative details are described.
- Heat-exchange apparatus.** Emmett F. Annis. U. S. 1,932,950, Oct. 31. Structural features.
- Plate heat exchangers for drying apparatus, etc.** Soc. pour l'ind. chim. à Bâle. Brit. 395,005, July 20, 1933.
- Plate heat-exchangers for fluids.** Reginald L. Munday. Brit. 396,696, July 31, 1933.
- Apparatus for heating and distilling water.** Marie P. Beraud. U. S. 1,931,838, Oct. 24. Structural features.
- Means for the automatic control of air-humidifying apparatus.** Brecknell, Munro & Rogers (1928) Ltd. and Henry J. Dolman. Brit. 396,426, Aug. 2, 1933.
- Apparatus for producing crystals from concentrated solutions.** Compagnie de produits chimiques et électro-métallurgiques Alais, Froges et Camargue. Brit. 396,613, Aug. 10, 1933.
- Means for preventing accumulation of air in a pump for delivering measured quantities.** Andreas Stuhl. Brit. 397,083, Aug. 17, 1933.
- Steel pallet for sintering apparatus.** Albin P. Wutzke. U. S. 1,932,496, Oct. 31.
- Safety screen device suitable for use in openings of containers such as those for holding volatile combustible liquids.** John E. Simmonds and Charles Peterson. U. S. 1,933,486, Oct. 31. Structural details.
- Apparatus for conditioning air by water sprays.** Samuel M. Anderson (to B. F. Sturtevant Co.). U. S. 1,933,039, Oct. 31. Structural and operative details.
- Pressure-resisting closures for vessels such as used for liquid carbon dioxide.** Cecil S. Hall (to Imperial Chemical Industries Ltd.). U. S. 1,932,135, Oct. 24. Mech. features.
- Apparatus for indicating the density of liquids in tanks, vacuum pans, etc.** Fred J. Postel. U. S. 1,932,228, Oct. 24. Various structural and operative details are described.
- Device for diffusing and radially distributing a gaseous fluid, more particularly air for ventilation, but also adapted for use in dust-separating apparatus.** Norman F. Johnston. Brit. 396,468, Aug. 10, 1933.
- Apparatus for oxidizing carbon monoxide such as that produced by internal-combustion engines.** Isidore Pasternack (8% to Harry E. Brown). U. S. 1,933,997, Nov. 7. Structural details.
- Container for bleaching solutions such as those used with peroxide solutions.** Willi Hundt (to Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler). U. S. 1,931,798, Oct. 24. A container resistant to the action of active O compds. and to sudden changes in temp. comprises a strong outer vessel which may be formed of brickwork, a thin inner vessel of concrete not influencing or influenced by active O compds., and an intermediate layer of non-coherent heat-insulating material such as loam, diatomite or asbestos.
- Device for determining the percentage of potassium in chambers containing potassium such as mines.** Werner Kolbster. U. S. 1,933,063, Oct. 31. Various structural and operative details are given of a device for detg. K by means of its emitted  $\gamma$ -rays.
- Apparatus for testing and recording the tensile strength of materials.** Frank A. Valentine (to Henry L. Scott Co.). U. S. 1,935,421, Nov. 14. Structural and mech. features.
- Mixing valve suitable for use with hot and cold fluids.** Clyde M. Hamblin. U. S. 1,932,404, Oct. 31.
- Mixing device for liquid, semi-liquid and powdery materials.** Paul Lenart. Ger. 577,946, June 7, 1933. Addn. to 576,528 (C. A. 27, 5586).
- Apparatus for extracting soluble material from mixtures of insoluble and soluble materials to estimate the relative solubility of the latter.** Paul Köttgen. Ger. 577,579, June 1, 1933.
- Apparatus for estimating the relative proportions of solids of different particle size in gases.** Zeiss Ikon A.-G. (Hans Tappen, inventor). Ger. 586,026, Oct. 14, 1933.
- Machine for estimating the water content of sand, etc.** Toledo Scale Mfg. Co. Ger. 586,115, Oct. 18, 1933.
- Apparatus for coating sheets of glass, porcelain, enamel, cellulose acetate or condensation products of formaldehyde with phenol or urea with solutions of wholly or partially polymerized or polymerizable unsaturated organic compounds such as vinyl acetate, butadiene and esters of acrylic or metacrylic acid.** Röhm & Haas A.-G. Brit. 396,097, July 31, 1933.
- Roller-and-breast mills.** Lionel G. Holmes. Brit. 396,663, Aug. 10, 1933.
- Ball-and-ring mills.** Ervin G. Bailey, Perry R. Cassidy and Ralph M. Hardgrove (to Babcock & Wilcox Ltd.). Brit. 396,614, Aug. 10, 1933.
- Ball mills with drying means.** Frantisek Wiesner and Vratislav Malik. Brit. 396,608, Aug. 10, 1933.
- Grinding mills and apparatus.** George Porteus. Brit. 396,400, Aug. 2, 1933. In a mill in which the dust-laden air is discharged to a cyclone, the air returning to the mill in a closed circuit, the air outlet of the cyclone has associated therewith a hood or canopy delivering into the substantially closed path or circuit.
- Floating roof and seal for tanks.** Clayton L. Day (to Chicago Bridge & Iron Co.). U. S. 1,932,398, Oct. 31.
- Floating roof for tanks for holding volatile oils, etc.** Harry C. Boardman (to Chicago Bridge & Iron Co.). U. S. 1,932,394, Oct. 31.
- Tank (with a floating roof) for storage of liquids.** Otterbein A. Bailey (to Chicago Bridge & Iron Co.). U. S. 1,932,392, Oct. 31. Structural features.
- Tank (with a floating roof) for holding volatile oils, etc.** Walter Garske (to Chicago Bridge & Iron Co.). U. S. 1,932,403, Oct. 31.
- Acetylene generator of the carbide-feed type.** Eston W. Weaver. U. S. 1,932,565, Oct. 31. Structural and mech. details.
- Thermostats.** John L. Hodgson, Alexander Ivanoff and Giles P. E. Howard. Brit. 396,085, July 17, 1933. Temps. that are measured by thermocouples or elec. pyrometers or flows whose rate is made to cause a voltage variation are controlled by arranging the thermocouple, pyrometer or resistance in a Wheatstone bridge, potentiometer or ratiometer which is balanced only at the desired temp., clamping the galvanometer or ratiometer pointer intermittently and causing the clamped pointer to control the temp. or flow.
- Thermostatic device suitable for controlling the mixing of hot and cold fluids.** Chester I. Hall (to General Elec. Co.). U. S. 1,934,499, Nov. 7. Structural and mech. details.

## 2-GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Egbert Watson Magruder. Wortley F. Rudd. *Ind. Eng. Chem.* 25, 1406(1933).—Biography with portrait.

G. G.

Notes on Liebig. H. Waldeck. *Pharm. Zentralhalle* 74, 548-51(1933).

W. O. E.

Public liability and chemical education. II: Earthquake precautions in the chemistry laboratory. Park L. Turrill. *J. Chem. Education* 10, 721-5(1933); cf. *C. A.* 27, 4723.

E. H.

Developments in chemical engineering education. D. B. Keyes. *J. Chem. Education* 10, 717-20(1933).

—E. H.

Developments in the teaching of chemistry and chemical engineering at King's College, London. Anon. *Ind. Chemist* 9, 393-6(1933).

E. H.

Class exercises in the industrial chemistry course. II. Economic survey of a chemical commodity. Kenneth A. Kobe. *J. Chem. Education* 10, 738-40(1933); cf. *C. A.* 28, 9.

E. H.

Lecture demonstration of the arc process. Paul Arthur and Cecil V. King. *J. Chem. Education* 10, 748(1933).

E. H.

Development of the electronic theory of valency. C. A. Buchler. *J. Chem. Education* 10, 741-5(1933).

E. H.

Relations between stereochemistry and physics. Peter Debye. *J. Chem. Soc.* 1933, 1386-71.—Fifteenth Faraday lecture.

G. G.

New method of colorimetry. R. A. Houston. *Phil. Mag.* 16, 945-53(1933). A simple method for describing colors is presented which requires only common app. such as a spectrometer and Nicol eyepiece.

B. J. R.

Coldrimetry with photoelectric cells. Rudolf Seifert. *Suddeut. Apoth.-Ztg.* 73, 507 8(1933).

W. O. E.

The virial and molecular structure. J. C. Slater. *J. Chem. Phys.* 1, 687-91(1933); cf. *C. A.* 26, 5799.—The virial theorem is applied to a mol. if external forces are applied to keep the nuclei fixed. It permits sep. detns. of the kinetic and potential energies for all configurations of the nuclei from the total-energy curves as derived from expt. or theory. Such potential- and kinetic-energy curves are derived for simple forms of the total-energy curves for diatomic mols. These can be readily interpreted as indicating bond formation in attractive forces. The method can be extended to apply to more complicated mols. and to solids.

M. M.

The occurrence of univalence in the system of the elements. Hans Schmid. *Angew. Chem.* 46, 691-7(1933).—A comprehensive treatise on the subject of univalence based on the theory of at. structure. With the exception of the alkali and alk. earth metals about 18 elements form univalent compds. Of these 11 fall in the 8th, 7th and the 1st groups. Only Rh, Os and Ir of the 8th group are not known to exhibit univalence. Forty-one references.

Karl Kammermeyer

The diamagnetic susceptibility of the hydrogen molecule. Kōtarō Honda and Tokutarō Hirone. *Z. Physik* 84, 204-11(1933).—The  $H_2$  mol., apart from its diamagnetism, shows a paramagnetism due to the magnetic moment set up by thermal rotation. This paramagnetism is independent of temp. and accounts for the difference between the observed and calcd. susceptibility.

R. Peierls

Permeability of iron (to 100 meter waves) in a high-frequency field. V. Uguison. *J. Tech. Phys.* (U. S. S. R.) 1, 814-22(1931).—The permeability decreases as the frequency increases. The decrease does not depend essentially on the species of iron.

F. H. Rathmann

Paramagnetic properties of  $Co^{++}$  in very dilute solution. R. Mercier. *Helv. Phys. Acta* 6, 240-2(1933); cf. *C. A.* 27, 1804.—The variation of magnetic susceptibility of  $CoCl_2$  soln. with temp. and concn. is measured. The Curie const. is independent of concn., but diminishes with temp. The no. of Weiss magnetons drops from

24.3 at room temp. to 18.1 at 177°K. These results are at variance with the values expected from spectroscopic data as the angular momentum is most probably coupled to the surrounding solvent mols.

E. B.

Temperature and pressure dependence of the dielectric constant of gaseous bromine and iodine chloride. Karl F. Luft. *Z. Physik* 84, 767-82(1933).—The dipole moment of Br is less than  $10^{-18}$  e. s. u.; that of ICl is about  $5 \times 10^{-19}$ .

R. Peierls

Anomalous dispersion of the dielectric constant of Rochelle salt. Georg Busch. *Helv. Phys. Acta* 6, 315-36(1933).—The observation of Errera (*C. A.* 25, 3916) that Rochelle salt possesses an anomalous dispersion of the dielec. const. is confirmed. This anomaly in the region of  $\lambda = 2000$  m. is due to piezoelec. oscillations because the crit. frequency varies with the dimensions of the crystal. The bridge method of detg. the dielec. const. with cond. compensation is described. Directions for growing single crystals of Rochelle salt are given as well as a very useful method of cutting the crystal and polishing it.

Egon Bretscher

Investigation of the space charges in ice. G. Oplatka. *Helv. Phys. Acta* 6, 198 209(1933).—The dielec. const. at very low frequencies was found previously to exceed 150. The course of the potential in a capacity contg. ice as dielec. was detd. with a test rod. A linear increase of potential as a function of the distance from the electrodes was found for very pure ice, but a sharp rise in close proximity of ice contg. traces of  $CO_2$  or  $NH_3$ . This proves that the high dielec. const. above 80 of impure ice is due to space charges.

Egon Bretscher

The polar structure of molecules and the nature of the secondary valence forces. Gunther Briggleb. *Z. physik. Chem.* B23, 105-30(1933).—A discussion of van der Waals forces in the mol.

G. M. Murphy

Polarity of chemical compounds. III. Ken'ichi Higashi. *Bull. Inst. Phys.-Chem. Research* (Tokyo) 12, 771-9(1933) (Abstracts 1 (in English) published with *Sci. Papers Inst. Phys.-Chem. Research* (Tokyo) 22, Nos. 450 3); cf. *C. A.* 27, 2358.— $Et_2O$  was further examd. as a solvent for the elec. moment detn. Dielec. const. and d. of the same at different temps. were detd. for solns. of  $EtOH$  (I),  $(CH_3OH)_2$  (II) and  $AcOH$  (III). The elec. moments of solute mols. were calcd. as follows: I  $-60^\circ$  1.5;  $-40^\circ$  1.6;  $-20^\circ$  1.6;  $0^\circ$  1.6;  $10^\circ$  1.7,  $25^\circ$  1.79. II  $-60^\circ$  1.2;  $-40^\circ$  1.6;  $-20^\circ$  1.9;  $0^\circ$  2.3;  $20^\circ$  2.3. III  $-60^\circ$  0.7;  $-40^\circ$  0.8;  $-20^\circ$  0.9;  $0^\circ$  1.0;  $15^\circ$  1.1;  $20^\circ$  1.17;  $25^\circ$  1.23 (unit  $10^{-18}$  e. s. u.). I shows a very simple polarization component curve and satisfies approximately Debye's equation  $P_{\infty} = a + (b/T)$  in  $Et_2O$ , while this equation is not applicable to II or to III. IV. *Ibid.* 780-9.—Dielec. const. and d. were detd. for solns. of cetyl alc. (I) and  $\alpha$ - (II) and  $\beta$ -naphthols (III) in  $PhH$  (IV),  $C_6H_6$  (V) and  $Et_2O$  (VI), and the elec. moments of solute mols. were found as follows: I  $20-60^\circ$  1.70-1.09 (in IV);  $20-60^\circ$  1.30-1.58 (in V);  $0-20^\circ$  1.79 (in VI); II  $20-60^\circ$  1.40-1.43 (in IV);  $26^\circ$  1.91 (in VI); III  $25^\circ$  1.53 (in IV) (unit  $10^{-18}$  e. s. u.). The dipole moment values of I are const. in the temp. range  $0^\circ$  to  $60^\circ$ , and are the same as those of lower aliphatic alcs.; the moments of II and III found in IV are a little smaller than those of other alcs. but are far greater than the values 1.00 and  $1.3 \times 10^{-18}$  e. s. u. given by Puchalik for II and III (cf. *C. A.* 26, 3708).

K. K.

Report on the paramagnetic rotatory polarization. Jean Becquerel and W. J. de Haas. *Rapports et Communications*, No. 31, 6e Congr. intern. froid, Buenos Aires; *Communications Kamerlingh Onnes Lab. Univ. Leiden Suppl.* 74, 1-35(1932); cf. *C. A.* 26, 3154-5.—The Faraday effect is readily due to 2 phenomena, one connected with diamagnetism, the other with paramagnetism. These effects can be sep'd., in some minerals and uniaxial crystals contg. some of the rare earths, by magneto-optical expts. at very low temps. The re-

**Kolloid-** 65, 25-31 (1933) **Max viscosity in the ternary system was found at 10% alc., 55%  $C_2H_5$ .** In a binary system  $H_2O-C_2H_5$ , the max. was little pronounced, because of the lack of charge at the interface. No max. was found in the systems petroleum or petroleum oils with  $H_2O$ .  $HCl$  and  $NaOH$  diminish the viscosity at higher oil concns. but no max. occurs. A. I.

**Form elasticity of thin layers of water.** B. Derjagin / *Physik* 84, 69-70 (1933). Layers of water of a thickness less than  $1.5 \times 10^{-7}$  cm. brought between glass plates, show the elastic behavior of solids, i.e., they can transmit transverse stresses. R. Peierls.

**Theory of thermoelectric potential between semiconductor and metal according to Fermi statistics.** G. Monch / *Physik* 83, 47-52 (1933), cf. C. 1, 27, 1433. The contact of a metal and a semiconductor represents a transition from an entirely degenerated Fermi gas of electrons to a non-degenerated classical gas. A combination formula therefore applies. The formula agrees accurately with the measurements on CuO. R. Peierls.

**Some electrical properties of calcite.** Sadakichi Shimizu / *Sci. Repts. Tohoku Imp. Univ.*, First Ser. 22, 50-98 (1933). From measurements of residual charge and its recovery time it is concluded that Japanese calcite has no condensed polarization. The apparent cond. is affected by the previously applied potential. At  $2^\circ$  the resistance for the direction of the  $c$  axis is 10 times greater than for the direction perpendicular to the  $c$  axis. The variation of cond. due to the direction of the parallel specimen begins at  $0.80^\circ$  and continues to  $8.50^\circ$ , but the variation for the other appears in a range from  $8.50^\circ$  to  $8.10^\circ$ . I. G. Vanden Boesche.

**Effect of surface charges on measurements of the conductivity of poor conductors.** A. D. Goldammer / *Physik* 84, 11-14 (1933). The condition under which surface charge seriously affects such measurements were studied. In the expt. of Seiff / *Physik* 76, 63 (1932) insufficient care was taken to avoid error from this source. I. Peierls.

**Preparation and properties of thin lead sulfide films with special reference to their detector action.** I. Gerhard Bruchmann / *Z. Phys.* 65, 11-14 (1933). Mirrors of PbS are produced by immersion in a lead salt sol., and prep'd by mixing quickly a part of  $H_2O$  with 4 parts of a mixt. of 1 part of  $H_2O$ , 11  $AgNO_3$  to 1 part of 2% thionurea (cf. Colbert, C. 1, 22, 1141). Perfect mirrors are obtained only when the soln. remains clear for 1 min. after immersion. The films present a complex ion whose compn. is catalyzed by  $OH$  ion. Colloidal PbS is first formed. The pptn. of PbS from the complex is complete. Expt. at various temp. indicate a temp. coeff. of  $2^\circ$  for the velocity. Addn. of Sn, Sb or As helps form perfect mirror. The PbS mirrored on quartz mirrors  $Fe$ ,  $Pt$ ,  $Fe$ ,  $W$ ,  $Cr$ ,  $Ag$ ,  $Pb$ ,  $Su$  and  $Ni$  but not on  $Cu$  or  $Cu$  alloys. If the plate was mirrored after the initial cloudiness developed, a local non-mirroring deposit formed. The PbS deposited as a mirror was proportional to the surface extent, and varied from 0.22  $\mu$  thickness on quartz to 0.14 on  $Ni$ . Arthur Heller.

**Variation in the electrical conductivity of some hydrous minerals with temperature.** Sadakichi Shimizu / *Science Repts. Tohoku Imp. Univ.*, First Ser. 22, 63-64 (1933), see C. 1, 27, 1476. G. G.

**The electric conductivity of  $Cu_3Pd$  and  $Cu_3Pt$  alloys with superlattice and random structure at low temperatures.** H. J. Seemann / *Physik* 84, 59-64 (1933). The resistance curve of these alloys does not depend upon whether they show a random distribution of the 2 kinds of atoms over the possible sites or a superlattice structure. R. Peierls.

**Superconductivity of alloy systems.** J. I. Allen / *Phil. Mag.* 16, 1005-11 (1933). The supercond. of the following alloy systems was studied over the entire compn. range:  $Au-Sn$ ,  $Au-Pb$ ,  $Ag-Sn$ ,  $Ag-Pb$ ,  $Cu-Sn$ ,  $Cu-Pb$  and  $11-Su$ . The changes in supercond. with compn. are related to the phase diagram of the alloy. Supercond. is a property of the complete structure of an alloy

and not a property of one of the components. Alloy structures can be divided into 3 types: (1) Simple eutectic mixts. have a const. supercond. point. (2) Mixed crystal phases have a continuous varying supercond. point and transition interval. (3) Regions of which both components form mixed crystal are similar to (2). In this type the transition temp. varies inversely with the magnitude of the lattice constant. I. J. R.

**Ultra light alloys of great strength.** S. A. Pogodin / *Ann. Inst. anal. phys. chim.* 6, 295-310 (1933). A review of phys. chem. properties of com. Mg metal and phys. chem. properties and compn. diagram of alloy of Mg with metals of the 1st, 2nd and 3rd group of the periodic system. Sixty-two references. S. I. Madorsky.

**Nature of polish layers.** J. A. Durby and K. K. Dixit / *Phil. Mag.* 16, 961-11 (1933). The surfaces of the following elements were highly polished and then examined by means of electron diffraction: Bi, Sb, Zn, Fe, Cd, Au, Ag, Pb, Mo, Cu, Cr, S and Si. In all the cases the pattern obtained consisted of 2 diffraction rings, indicating that the polished layer is amorphous and resembles a supercooled liquid. From the position of the rings the interatomic distances were obtained. These distances are smaller than normal for those metals which are near the minimum of the  $\alpha$  vol. curve, except for S and Si, which retain their normal distance. This led to the possibility of a normally high surface for some metal. It is possible that the surface atoms of conductors are trapped of their outer electrons. The ring observed with polished PbS and FeS are due to the small size of the crystals after polishing. I. J. Rosenblum.

**The elastic constants of single crystals of copper.** Kenichi Kimura / *Sci. Repts. Tohoku Imp. Univ.*, First Ser. 22, 55-64 (1933). Elastic constants for monocryst. Cu were det'd. at room temp. by the static method. The Voigt moduli in c.g.s. units follow the elastic parameters:  $10^{10}$  are  $S_{11} = 1.91$ ,  $S_{12} = 0.52$ ,  $S_{44} = 1.63$ ; the moduli of elasticity ( $\times 10^{10}$ ) are  $E_{11} = 0.77$ ,  $E_{12} = 1.26$ ,  $E_{13} = 1.49$ ; the moduli of torsion ( $\times 10^{10}$ ) are  $\mu_{11} = 0.41$ ,  $\mu_{12} = 0.50$ ,  $\mu_{13} = 0.1$ . The anisotropy of Cu is conspicuous. I. G. Vanden Boesche.

**The structure of real crystals.** I. Zwicky / *Helv. Phys. Acta* 6, 210-1 (1933). The evidence indicating a secondary structure of crystals is summarized. The objection of Otowin (C. 1, 27, 1794) are discussed. Bibliography. I. J. Brutscher.

**X-ray investigations in the system (zinc cadmium) antimony.** H. I. Hall, H. Nowotny and H. Tompa / *Ann. d. Chem.* 214, 190-200 (1933). The form and dimension of the elementary bodies of CdSb were worked out as follows:  $a = 0.41$ ,  $b = 1.01$ ,  $c = 0.16$ .  $V = 0.0066$ .  $d = 100$ .  $\rho = 5.90$  g./cm<sup>3</sup>. The crystal form is monoclinic. The no. of mol. in the elementary body is derived from  $d$  of 6.2 and mol. wt. 280.8 ( $\times 1.1$ ) or approx. 4. ZnSb is isomorphous with CdSb, is of rhombic form with the following dimension:  $a = 0.17$ ,  $b = 0.24$ ,  $c = 0.94$ .  $V = 0.0026$ .  $\rho = 5.72$  and  $d$  of 6.38, leading to  $n = 4.1$ . CdSb shows the same monoidal form as the corresponding Zn compd. Crystals of ZnSb show pseudomorphous phase. The phase primarily cpd. is further differentiated into Zn and ZnSb. This is also indicated by the change in  $d$  accompanying pulverizing or tempering. Resulting modification of the phase diagram of the ZnSb system are discussed. C. J. Humphreys.

**An elementary deduction of Gibbs' adsorption theorem.** I. O. Koenig and R. C. Swann / *J. Chem. Physics* 1, 23-20 (1933). An exact elementary deduction of Gibbs' adsorption theorem and some related equations is given by means of a suitable thermodynamic engine. The assumptions underlying the Gibbsian treatment of the thermodynamics of surfaces are discussed briefly. The relation of the equations related to the corresponding general Gibbsian equation is explained. M. M.

**A statistical derivation of the adsorption isotherm of binary gas mixtures.** G. Damkohler / *Physik. Chem.* B23, 58-68 (1933). The adsorption isotherm was de-

rived statistically for a binary gas mixt. covering a surface with a monomol. layer. Concn., pressure and temp. dependence are discussed. G. M. Murphy

**Adsorption of CO derivatives. IX. Effect of solvent on reaction rate.** Gertrud Buttmann. *Z. physik. Chem.* B23, 100 4(1933); cf. *C. A.* 26, 5257. The reaction between  $\text{CCl}_3\text{CHO}$  and  $\text{FIOH}$  was studied in hexane, cyclohexane, cyclohexene,  $\text{CCl}_4$ ,  $\text{EtCOEt}$ , dihexane,  $\text{Et}_2\text{O}$  and  $\text{CHCl}_3$ . G. M. Murphy

**An analysis of hydrogen adsorption phenomena.** M. C. Johnson. *Trans. Faraday Soc.* 29, 1139 55(1933). The kinetics and heat effects of adsorption, desorption and disson of  $\text{H}_2$  mol. and of adsorption, desorption, soln. or recombination of  $\text{H}$  atoms in the presence of metals and of nonmetals are considered separately and also in various conceivable combinations. Several of the type cases considered are shown to characterize the results obtained by workers in exptl. studies of various  $\text{H}_2$  solid systems. P. H. Emmett

**The adsorption of nitrogen-argon mixtures.** G. Damböhrer. *Z. physik. Chem.* B23, 69 88(1933).—Adsorption isotherms were obtained for N and A on  $\text{SiO}_2$  gel at 89.5° and 111° abs. and their mixts. at 89.5°, 111° and 163° abs. at pressures between 100 and 700 mm. Hg. A few measurements were also made on uricite, charged with  $\text{CO}_2$  and gas-free at 111° and 250 mm. pressure. G. M. Murphy

**The sorption of vapors by nitrocellulose.** J. W. McBain, S. J. Good, A. M. Bakr, D. P. Davies, H. J. Willavoy, and R. Buckingham. *Trans. Faraday Soc.* 29, 1096 100 (1933). The quantities of different vapors retained by nitrocellulose in equil. with various partial pressures of their vapors differ 100 fold between the indifferent solvents and the best solvents. At low relative pressures sorption laws are followed; with increasing sorption pores are opened and capillary condensation occurs. Gels have more pore space than ungelatinized fibers. When nitrocellulose contg. sorbed vapor is heated for 3 or 4 days at 60° a change that is tentatively called "consolidation" occurs, diminishing the sorptive power of the nitrocellulose. P. H. Emmett

**Fractionation and purification of organic substances by the principle of chromatographic adsorption analysis. I.** Alfred Winterstein and Gertrud Stein. *Z. physik. Chem.* B22, 247-63(1933). The chromatographic adsorption method introduced by Tswett (*C. A.* 5, 2835) for analytical purposes is in many cases admirably adapted to the preparative sepn. of mixts. that are difficult to sep. by fractional crystn. It is applicable not only to pigments but also to the sepn. of colorless substances. Satisfactory sepn. were made of ergosterol and cholesterol, oleanol and oleanylene, dipalmityl ketone and hentriacontane. An activated and standardized  $\text{Al}_2\text{O}_3$  is used as adsorbent, and usually benzine as solvent. II. **Chlorophylls.** *Ibid.* 263-77.—By using powd. sucrose as adsorbent chlorophylls *a* and *b* were preparatively sepd. from crude chlorophyll by the method of chromatographic adsorption analysis. The absorption bands reported in the literature for the 2 chlorophylls should be superseded by the new detns. made on the pure preps. As a criterion of purity of chlorophyll preps. the detn. of extinction coeffs. is recommended. The adsorption method is applicable also to the sepn. of chlorophyll derivs. and permits the detection of traces of impurities in chlorophyll preps. It is adapted to the detn. of the chlorophyll components in minute quantities of plant material. A. W. Dox

**Formation of nuclei of condensed vapors in non-ionized dust-free air. II. The system methanol-water.** J. A. Frommke, C. R. Bloomquist and E. X. Anderson. *Z. physik. Chem.* A166, 305-15(1933); cf. *C. A.* 24, 8. — The condensation phenomena during the adiabatic expansion of a series of  $\text{MeOH-H}_2\text{O}$  mixts. in dust-free air were studied. The fact that each mixt. condenses more easily than the pure components is attributed to coalescence. G. M. Murphy

**Physicochemical analysis and surface molecular forces. Heat of melting and inversion of composition-properties diagram.** B. V. Il'in, V. A. Oshman, N. L. Rehenko

and N. K. Arkhangelskaya. *Ann. inst. anal. phys.-chim.* 6, 91 6(1933).—Expts. on wetting powd. charcoal with a soln. of  $\text{AcOH}$  in  $\text{H}_2\text{O}$  show that the curve expressing the relation between heat of wetting and percentage compn. of soln., consists of 2 parts intersecting at a point near 50 mol%  $\text{Ac}_2\text{O}$ . S. L. Madorsky

**Liquid drops on the surface of the same liquid.** L. D. Mahajan. *Z. Physik* 84, 676(1933).—The effect described by M. (cf. *C. A.* 27, 1250) is due to a thin layer of air between the drop and the rest of the liquid. This was proved by observing Newton's rings from this air layer and the scattering of light from its boundaries. R. Peierls

**A theory of the phenomenon of liquid drops on the surface of the same liquid.** L. D. Mahajan. *Kolloid-Z.* 65, 20 3(1933); cf. *C. A.* 25, 14. The equation  $L = \gamma a^2 / \nu V$ , where  $L$  is the life of the drop on the surface,  $\gamma$  a const.,  $\nu$  the viscosity of the soln.,  $V$  the viscosity of the surrounding medium, and  $\gamma$  the viscosity of the soln. whose drops have a max. life, represents the exptl. data. The stability of the drops is due to a thin air film surrounding the drops. Smaller drops are more stable because they exert less pressure on the film. Arthur Fleischer

**Viscosity of emulsions.** E. G. Richardson. *Kolloid-Z.* 65, 32 7(1933); cf. *C. A.* 24, 992. Viscosity and velocity distribution in  $\text{CaH}_2\text{-H}_2\text{O}$  emulsions were detd. in a Couette-type and a hot-wire viscometer. Concd.  $\text{CaH}_2$  in aq. emulsions shows a marked structure viscosity and with high concns. assumes a margarine-like consistency. At mean velocities, the data are reproduced by the equation,  $\log(\eta/\eta_0) = k\Phi$ , where  $\eta$  and  $\eta_0$  are the viscosities of the emulsion and dispersant, resp.,  $k$  is a const., and  $\Phi$  the vol. of the disperse phase. A. F.

**Theory of electrocapillarity.** I. S. R. Crasford, O. Gatty and J. St. L. Philpot. *Phil. Mag.* 16, 819 61(1933).—The concepts of surface tension and surface work are discussed and a generalized app. for doing surface work is described. The surface tension can be defined in such a way as to be applicable to a boundary of finite thickness. The phase rule is extended to include extensive degrees of freedom. A system of  $P$  phases and  $C$  components has  $C + 2$  degrees of freedom of which  $P$  refer to extensive properties. The effect of a gravitational field is considered. F. J. Rosenbaum

**Remarks on the paper by M. Satō: "The effect of heat flow on the Brownian movement."** I. Kurt Sitte. *Z. Physik* 83, 266-9(1933). The calcs. of Satō's paper (*C. A.* 27, 2363) are based on a principle not applicable to this problem and contain math. errors. R. P.

**The lower limit of particle sizes in disperse systems.** Gogoberidze. *Kolloid-Z.* 65, 24 5(1933).—By substituting the value of 1033 cm. the vapor pressure at the b. p., in Kelvin's equation for the change of vapor pressure with surface curvature, limiting radii for liquid droplets can be calcd. For  $\text{H}_2\text{O}$ , the particle size increases from  $7 \times 10^{-8}$  at 0° to  $128 \times 10^{-8}$  cm. at 50°.

Arthur Fleischer  
**Wetting experiments with hydrophilic and hydrophobic powders in systems of two immiscible liquids. III.** E. Berl and B. Schmitt. *Kolloid-Z.* 65, 83 100(1933); cf. *C. A.* 27, 618.—Sepn. of 2 powders by flotation method is indicated in the water-benzene emulsification test by sepn. of the 2 solids in sep. films at the liquid-liquid interface, and by the complete wetting of 1 solid at the  $\text{CaH}_2$  interface with exclusion of the other. Although crystal violet makes quartz hydrophobic it is displaced from the interface by anthracite. Marble treated with cloth red is not displaced from the interface by anthracite powder. Artificial mixts. of Freiberg galena and Clausthaler sphalerite show little difference in wetting when aged. In  $\text{Na}_2\text{CO}_3$  or  $\text{NaCN}$  solns. they are readily sepd. by addn. of aniline, *o*-toluidine, or creosote soln. The activating action of  $\text{CuSO}_4$  on sphalerite is due to the irreversible adsorption of Cu ion with subsequent oriented adsorption of xanthate. A. F.

**Osmosis in systems consisting of water and tartaric acid and containing three liquids, separated by two membranes. II.** F. A. H. Schreinemakers and H. H.

Schreinemachers. *Proc. Acad. Sci. Amsterdam* 36, 620-35(1933); cf. *C. A.* 27, 5226-7.—A membrane made of sheets of Cellophane and pig bladder in intimate contact was placed between  $H_2O$  and a soln. of tartaric acid. When the Cellophane was in contact with  $H_2O$ , an aq. layer formed between the 2 parts of the membrane; on interchanging the liquids, the inter-membrane soln. disappeared, and the 2 parts of the membrane adhered closely. The equil. attained with the combination membrane was the same as that attained with the bladder alone; the rate of osmosis was much smaller.

Gerald M. Petty

**Electroosmosis. I. The electrokinetic potential difference at the interface of some acidic electrolytes of several concentrations.** Hajime Isobe and Sadami Imai. *Bull. Inst. Phys.-Chem. Research (Tokyo)* 12, 790-813(1933) (Abstracts 2 (in English) published with *Sci. Papers Inst. Phys.-Chem. Research (Tokyo)* 22, Nos. 450-3).—The electrokinetic potential differences were calc'd. by detg. the velocities of acidic electrolyte solns. in electroosmosis. The electrokinetic potential  $\xi$  in each acidic soln. increases at first with increasing concn. to the max. and then decreases. The relation between  $\xi$  and the concn.  $c$  is expressed by the equation  $\xi = \xi_0 e^{-\beta c} - (\xi_0 - \xi_\infty) e^{-\gamma c}$ , where  $\xi_0$  is the value obtained by extrapolating the  $\log \xi - c$  curve to zero concn.,  $\xi_\infty$  is the electrokinetic potential of the cond. water of  $0.6 \times 10^{-8}$  mho of sp. cond., and  $\beta$  and  $\gamma$  are consts. characteristic of acids. The values of  $\xi_0$  (v.),  $\beta$ ,  $\gamma$ ,  $C_m$  (millimol./l.) ( $c$  corresponding to the max.  $\xi$ ) and  $\alpha$  ( $\alpha$  degree of dissociation) were calc'd. as follows: HCl 0.0911, 0.387, 17.1, 0.18, 0.18; AcOH 0.0905, 0.0401, 0.572, 3.81, 0.26;  $CH_3ClCO-H$  0.0902, 0.333, 12.2, 0.23, 0.21;  $HCO_2H$  0.0910, 0.212, 6.51, 0.41, 0.21;  $(CO_2H)_2$  0.0907, 0.375, 13.2, 0.21, 0.21; maleic acid 0.0904, 0.346, 12.2, 0.23, 0.23; fumaric acid 0.0906, 0.301, 9.55, 0.28, 0.23; succinic acid 0.0907, 0.0804, 1.59, 1.43, 0.28;  $H_3PO_4$  0.0907, 0.323, 11.9, 0.26, 0.26; citric acid 0.0904, 0.270, 8.34, 0.32, 0.25.

K. Konda

**Changes in the surface and structure of gels and minerals at high temperatures.** Jaroslav Splichal. *Chimie et Industrie Special No.* 757 81 (June, 1933). By detg. the  $H_2O$  adsorption and calcg. the angles of the lines of debyeograms, it was found that: (1) The surface of  $SiO_2$  gel does not change up to 500°; at 1000° the surface decreases to such an extent that it no longer adsorbs  $H_2O$  or dyes; only by heating in a blast lamp is it possible to obtain cristobalite; siliceous earth has a considerable surface and a relatively high  $H_2O$ -adsorption power. (2) Hydrated  $Al_2O_3$  gels and bauxites strongly adsorb  $H_2O$ , even after heating to 500° or 1000°; this is due to the  $Al_2O_3$ . (3) Hydrated  $Fe_2O_3$  gels change to hematite at 200°; at higher temps. crystn. proceeds and  $H_2O$  adsorption decreases. X-ray examn. showed that the ferric minerals examd. were solid solns. of goethite and  $H_2O$  and at 250° they exhibited the lines of hematite. The most recent hematite has a high  $H_2O$  adsorption, in spite of the fact that the sharpness of the debyeogram indicates a cryst. structure.

A. Papineau-Couture

**Action of electrolytes on solutions of kaolin.** Pichot. *Compt. rend.* 197, 451-3(1933); cf. *C. A.* 27, 5850.—The effect of variable quantities of electrolyte ( $NaCl$ ) on the flocculation or dispersing of kaolin was studied.  $L/t$  values ( $L$  = distance from the free surface to the observed layer,  $t$  = time of turbidity) when plotted against opacity lie on a curve for any given  $l/t$  concn. of  $NaCl$  and temp. being const. If the concn. of  $NaCl$  is increased beyond a certain value the  $l/t$ -opacity values lie on one curve as long as  $t$  remains const. There will be a sep. curve for each  $t$  value. Salts that below a certain concn. yield one uniform curve for values of  $l/t$ -opacity when  $t$  is variable are termed peptizing electrolytes, while the same salts above a certain concn., which yield a curve for each value of  $t$  when  $l/t$ -opacity is plotted, are termed flocculating electrolytes. Curves for  $NaCl$  are illustrated.

H. E. Messmore

**Calcium oxalate rings. A peculiar case of periodic**

**precipitate formation.** H. Döring. *Naturwissenschaften* 21, 675(1933).—A photomicrograph is given of rhythmic pptn. of Ca oxalate around an epidermal cell of the skin of an onion (*Allium cepa*) moistened with 0.1  $N$  K oxalate. Ca salts have moved out of the dead cell and formed the ppt. with the reagent outside of the cell around the diffusion center. The wider rings have the larger crystals.

B. J. C. van der Hoeven

**Colloidal sulfur solutions by the action of iodine on sodium sulfide.** A. Janek. *Kolloid-Z.* 65, 87(1933); cf. *C. A.* 27, 4402.—The reaction of dil.  $Na_2S$  soln. and alc. I produces an opalescent S sol which changes to a suspension in 24-36 hr.

Arthur Fleischer

**Iron oxide sols. II. The charge in irregular series.** A. Lottmoser and Ta-Yu Chang. *Kolloid-Z.* 65, 62-72(1933); cf. *C. A.* 27, 5612.—Irregular series were noted in the coagulation of pos.  $Fe_2O_3$  sols by  $KH_2PO_4$ . Aging had negligible effect. The crit. potentials were 39, -38 and -46 mv. The  $pH$  of the phosphate soln. had no effect on sol charge. With increasing phosphate concn., increasing Cl ion was liberated; constancy of exchange adsorption was reached at the first crit. point. Not all of the Cl of the micelles was exchangeable. Increasing phosphate was adsorbed until the sign of the sol changed.

Arthur Fleischer

**The electrical properties of colloids. III. Discrepancies between activities and conductivities in colloidal solutions.** Jnanendra Nath Mukherjee. *Kolloid-Z.* 65, 72-7(1933); cf. *C. A.* 27, 3129. The discrepancies are evident from calcns. of cond. and c. m. f. data of  $Al_2O_3$  and  $SiO_2$  sols.

Arthur Fleischer

**Viscometric investigation of solutions of natural compounds of high molecular weight. I. Rubber in toluene.** Markus Reiner and R. Schoenfeld-Reiner. *Kolloid-Z.* 65, 44-62(1933); cf. *C. A.* 24, 764; 25, 2613; 26, 890, 1495, 4738.—Pale crepe rubber, 0.13% moisture, 0.23% ash, d. 0.92, was dissolved in an atm. of  $CO_2$  in purified toluene and filtered. The viscosity of solns. was detd. in capillary and Couette-type viscometers. Since the previous history did not affect the results the research materials could be considered reproducible. Wall effects were absent, showing the solns. to be quasihomogeneous. Relative viscosity measurements from 0° to 40° gave the same relative consistency curve indicating that the non-Newtonian behavior is a purely mech. phenomenon. The general shape of the consistency curve is deduced from the measurements in the 2 types of viscometers. At very low and at high flows, a Newtonian behavior is indicated. The values at the inflection points are interpreted as the various viscosity values.

A. F.

**The viscosity of iron phosphate sol at varying pressures.** S. N. Banerji and S. Ghosh. *Kolloid-Z.* 65, 37-44(1933); cf. *C. A.* 24, 767, 2762, 4444, 5572.—With increasing dialysis, ferric phosphate sols prep'd. by mixing  $KH_2PO_4$  and concd.  $FeCl_3$  solns. become less stable and the viscosity increases. The increase in viscosity is less noticeable at higher pressures, which cause increased shear and decreased hydration. The viscosity change is not as great in dil. as in concd. solns.

Arthur Fleischer

**Further investigations on the viscosity and elasticity of sols.** Bruno Rabinowitsch. *Z. physik. Chem.* A166, 257-69(1933); cf. *C. A.* 24, 766.—The flow of cellite soln. in dioxane,  $MeOAc$  and furfural was studied in small capillaries.

G. M. Murphy

**Effect of electrolytes on the formation and decomposition of urate gels.** E. Gordon Young, F. F. Musgrave and H. C. Graham. *Can. J. Research* 9, 373-85(1933); cf. *C. A.* 27, 110.—The effect of various electrolytes in promoting gelation of aq. supersatd. solns. of the urates of methylamine, Li, piperazine and  $Me_4N$  was studied. The cation is the active agent. The min. concn. of the electrolyte that is effective was detd. over the gelation range of the urate. The order of efficacy of the cations is in general  $K > NH_4 > Rb > Cs > Li > Na$ . A max. concn. of electrolyte was found above which immediate pptn. rather than gelation occurs. The time required for gelation varies inversely with the amt. of

electrolyte present in any single concn. of urate. The rigidity varies directly up to the point of pptn. The time of crystn. of the gel varies directly with the concn. of the electrolytes, NaCl, RbCl and LiCl but inversely with KCl and  $\text{NH}_4\text{Cl}$ . Certain org. diamines possess the power of causing gelation over a limited range of urate. EtOH, between 20 and 60%, causes gelation of Li urate and methylammonium urate. The thixotropic effect was observed in gels of pipetazine urate contg. KCl and in Li urate with EtOH. The action of electrolytes on urate gels is interpreted as partially electrokinetic and partially lyotropic in nature. J. W. Shipley.

**Bound water of gelatin gels.** D. Jordan Lloyd and T. Moran. *Nature* 132, 515 (1933).—The percentage of bound water in gelatin gels was detd. by subjecting the gels in a collodion-impregnated canvas bag to pressures up to 2250 lb. per sq. in. At this pressure the gelatin concn. of the gel is 60%, confirming the value of 66% obtained through freezing expts. The pressure-concn. curves are the same for both 18.23° and 0°. Calvin Brous.

**The structure of cellulose gel. VII. The x-ray study of cellulose nitrate gel.** Katsumoto Atsuki and Masanori Ishiwara. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 540 1 (1933); cf. C. A. 28, 316. The cryst. structure of elastic gels prepd. from cellulose nitrate was studied. It was found that the structure of the cellulose nitrate film of N<sub>2</sub> content 11.2–11.4% is nearly amorphous, but a slight regularity and a decided direction of the mol. cryst. aggregate were observed in the x-ray diagram. The viscosity of the cellulose nitrate prepd. at a higher nitration temp. was lower than that obtained at a lower temp., which indicated that a mol. depolymerization occurred at the high nitration temp. The film of the cellulose nitrate of low viscosity showed a more diffused x-ray pattern, which suggests that the structure of such a film is more cryst., suffering less internal distortion, and giving weaker mech. properties. The film prepd. from an  $\text{Me}_2\text{CO}$  soln. of the cellulose nitrate has more uniform structure without internal distortion, while the film from  $\text{Et}_2\text{O}$ -EtOH soln. consisted of thready network structure, having an internal distortion as well as a heterogeneous distribution of mol. surface contact. K. K.

**A new type of shaking effect (thixotropy effect) in cellulose solutions, followed by means of changes of vapor pressure.** Max Ulmann. *Z. physik. Chem.* A166, 147–55 (1933).—Dil. solns. of acetylcellulose colloiddally dispersed in glacial AcOH show a higher vapor pressure than the pure solvent. This effect disappears in the course of time but can be restored by shaking the soln. A method is described for following the course of the effect.

G. M. Murphy

**Colloid chemistry of rice starch and boiled rice.** I. Ichiro Sakurada and Keiroku Futino. *Bull. Inst. Phys.-Chem. Research (Tokyo)* 12, 761–70 (1933) (Abstracts 1 (in English) published with *Sci. Papers Inst. Phys.-Chem. Research (Tokyo)* 22, Nos. 450–3).— $\beta$ -Starch contained in natural rice and giving a C-spectrum, is converted by boiling with water into  $\alpha$ -starch which gives a V-spectrum quite different from the former. On keeping the boiled rice at, or under, room temp.,  $\alpha$ -starch is again turned into  $\beta$ -starch giving a B-spectrum similar to the C-spectrum, whether or not water is lost. The boiled rice, dehydrated with EtOH directly after boiling, gives also  $\alpha$ -starch which shows a V-spectrum;  $\alpha$ -starch is thus stable, when the boiled rice contains less water, and if air-dried, it does not turn into  $\beta$ -starch.  $\alpha$ -Starch thoroughly freed from water at about 100° and giving a VT-spectrum absorbs water while kept in the room, and is converted into  $\alpha$ -starch showing a V-spectrum; this is, like the starch dehydrated with EtOH, stable for a long time. Addn. of water in optimal quantity gives at least röntgenographically almost the same product as boiled rice.

K. Konda

**The solubilities of some salts in liquefied ammonia. I. The solubility of sodium chloride and the saturated vapor pressure of the solution.** Suekichi Abe and Ryusaku Harō Hara. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding

557–9 (1933).—Data are presented for the soly. and vapor pressure of NaCl in liquid  $\text{NH}_3$ . K. K.

**Active oxides. LXIII. The solubility of active zinc oxides in ammonia.** Gustav F. Hüttig and Hans Schmeisser. *Kolloid-Z.* 65, 77–87 (1933); cf. C. A. 26, 5485; 27, 4157–8. The soly. of ZnO prepd. by ignition for 2 hrs. of  $5\text{ZnO} \cdot 3\text{CO}_2 \cdot 4\text{H}_2\text{O}$  at various temps., amorphous  $\text{Zn}(\text{OH})_2$  from  $\text{Zn}(\text{NO}_3)_2$  soln. and  $\text{NH}_4\text{OH}$ ,  $\text{ZnO} \cdot 1.85\text{H}_2\text{O}$  by drying cryst. hydrate over 70%  $\text{H}_2\text{SO}_4$ , and  $\text{ZnO} \cdot 1\text{H}_2\text{O}$  were detd. at 20° in  $\text{NH}_4\text{OH}$  by keeping the  $\text{NH}_3$  concn. const., varying the amt. of solid or time of shaking. Up to an ignition temp. of 600°, the ZnO attained a const. soly. in 90 min., which time increased with ignition temp. to blasting. The hydrates tended toward higher soly. but did not reach a const. value, because of slow dehydration, liberating a very active ZnO. The soly. of the ignited oxides increased linearly with the amt. of solid used until a const. point was reached. This point was at higher soly. and larger amts. of solid with decreasing ignition temp. If the soly. of ZnO is plotted against ignition temp., an inflection occurs at 550° in agreement with increased catalytic activity in MeOH decompn. above this temp. Free energy differences of the various ZnO preps. were calcd. from the soly. data. In KOH, the soly.-time curves show a max. soly., indicating a complicated behavior. In ignited ZnO the soly. data may be interpreted on the basis of 2 forms, an easily sol. and a difficultly sol. oxide. A. F.

**The rapid elimination of oxygen from water or aqueous solutions.** K. B. Mears and U. R. Evans. *J. Soc. Chem. Ind.* 52, 349–50 T (1933).—Satn. of  $\text{H}_2\text{O}$  with  $\text{CO}_2$  or N followed by evacuation (2 min. for each process), repeated 4 times, lowers the O content from 5.65 to 0.12–0.14 cc. per l.

H. A. Beatty

**Determination of vapor pressure of solutions. I. Total heat of solution, differential heat of dilution; theoretical heat of solution and activity coefficient of potassium chloride.** Zen-ichi Shibata and Kichizo Niwa. *J. Chem. Soc. Japan* 54, 996–1008 (1933).—By using the differential manometer (cf. C. A. 27, 1807) the vapor pressure of KCl from 0.2786 mol. to satn. was measured within the temp. range 0° to 10°. From the results of measurement total heat of soln., differential heat of soln., theoretical heat of soln. and the activity coeff. of KCl were calcd. Between 0° and 25° there is a relation between the concn.  $m$  (mol.) and the total heat of diln.  $L_d$  such that  $mL_d = -17,811$  cal.

T. Katsura

**The molecular weight of l-erythrose.** Venancio Deuloten. *Anales asoc. quim. Argentina* 21, 113 27 (1933); cf. C. A. 27, 958. The mol. wt. of l-erythrose in fresh aq. soln. was 129.9 and 131.8; after 4 hrs. it was 126.2 (calcd. 120).  $\text{Ac}_2\text{O}$  and pyridine acting on arabinose oxime form the acetonitrile of arabinonic acid, not the acetoxime. Treatment of triacetylerythrose with  $\text{NH}_3$ -alc. forms  $\text{H}(\text{OCH}_2\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}(\text{NHAc}))_3$ .

E. M. Symmes

**Determination of molecular weight of linseed oil and its polymerides.** P. J. Gay. *Chemistry and Industry* 1933, 703–5.—Ebullioscopic and cryoscopic methods for detg. the mol. wt. of fatty oils give variable results in different solvents. In a series of expts. attempting to obtain mol. wts., which could be given some theoretical interpretation, the solvents tried were benzene,  $\text{PhNO}_2$  and  $\text{PhCOMe}$ . The results with benzene and  $\text{PhNO}_2$  fully agreed with published figures.  $\text{PhCOMe}$  was less suitable on account of the supercooling effect prior to freezing. A chem. and phys. inert substance of suitable properties such as cyclohexane should provide the ideal solvent. It has a convenient and sharp f. p. of about 5.5°. The cryoscopic const. was detd. with naphthalene as solute in concns. varying from 0.1 to 1.2%. There was no change with concn. in the value of the const., being 212.5 on an av. of results agreeing within the limits of exptl. error. Linseed oil, which was sol. in all. concns., gave no variations in the mol. wt. with concn. and the values were within the limits of the theoretically possible. The values obtained were: acid-free oil, dried several

days in a vacuum over  $P_2O_5$ . 879, 880 and 876 at concns. of 6.3, 2.35 and 4.7%, resp. Undried oil: 867.5 at a concn. of 5.12%. Com. oil: 878 at a concn. of 3.5%. The same method could be applied to measure the mol. wt. of polymerides of linseed oil, giving values which remained const. at different concns. The method was applied with satisfactory results to oily polymerides of mol. wt. as high as 4320, although with such very viscous substances the estn. is less accurate, and it is doubtful whether results can be guaranteed within 3.5%. The discrepancies in values usually obtained must therefore be due to changes in the state of assocn. of the solvent used and the building up of large colloidal aggregates during heat-bodying of oils is fundamentally a chem. rather than a phys. phenomenon, the polymerides having a definite compn. and mol. wt. D. Timesen

**Rotatory dispersion of certain classes of organic molecules.** D. Biquard. *Ann. chim.* 20, 153 99(1933).—A systematic study of the optical activities of either phenyl- or diphenyl-succinic acids in various solvents and under different temp. conditions resulted in variations explainable only on the basis of 2 mol. forms in equil. The effect of solvents on phenyllactic acid, its Me ester, or benzylactic acid is explained by the existence of more than 2 forms in equil. W. J. Peterson

**The electrolytic dissociation of acids in salt solutions. VII. The dissociation constants and activity functions of a few hydroxy and keto acids in sodium chloride and potassium chloride solutions.** Erik Larsson. *Z. physik. Chem.* A166, 241 53(1933); cf. *C. A.* 27, 4467.—Many measurements of disson. const. and activity were made in NaCl and KCl soln. of hydroxy and keto acids. The results are compared with earlier measurements.

**Corrections to: "Electrolytic water transfer in sodium iodide solutions."** J. Baborovsky and A. Wagner. *Z. physik. Chem.* A166, 320(1933); cf. *C. A.* 27, 1805.

**Conductivity of iron chloride in non-aqueous solution.** Eugen Wertyporoch and I. Kowalski. *Z. physik. Chem.* A166, 205-18(1933); cf. *C. A.* 25, 4764.—Cond. measurements were made of  $FeCl_3$  dissolved in  $EtCl$ ,  $EtBr$ ,  $PrCl$ ,  $iso-PrCl$ ,  $BuCl$ ,  $iso-BuCl$ ,  $AmCl$ ,  $iso-AmCl$ ,  $C_6H_{13}Cl$ ,  $AcCl$ ,  $BzCl$ ,  $PhCH_2Cl$ ,  $PhCHCl_2$ ,  $PhCCl_3$  and of  $AlCl_3$  in  $BuCl$ ,  $iso-BuCl$ ,  $AmCl$ ,  $iso-AmCl$ ,  $C_6H_{13}Cl$ .

**The single potential of aluminum.** Hikojo Endo and Shigenori Kanazawa. *Sci. Repts. Tôhoku Imp. Univ.*, First Ser. 22, 537-52(1933). Though Si has no effect, the addn. of Fe considerably lowers the potential of Al. Three samples of Al gave different e. m. fs. due to varying impurities, particularly Fe, which was present to the extent of 0.29, 0.43 and 0.31%, resp. Samples I and II were mixed in varying amts. and then by extrapolating the potential-Fe content curve to 0% Fe the single electrode potential of Al was found to be 1.29 v.  $H_2$ ,  $N_2$  and  $CO_2$  caused no appreciable change but  $O_2$  lowered the potential greatly because of the formation of an oxide film. E. G. Vanden Boscche

**Colorimetric methods for the determination of pH.** J. M. de Castro Matçal. *Rev. brasil. med. pharm.* 9, 61(1933).

**Note on the electrometric titration of dl-2-thiolhistidine.** Geo M. Richardson. *Biochem. J.* 27, 1036-9(1933).—The disson. consts. of the compd. are  $pK_1 = 1.84$ ,  $pK_2 = 4.17$ ,  $pK_3 = 11.4$ . These figures correspond, resp., to the  $-COOH$ ,  $-NH_2$  and  $-SH$  groups. Benjamin Harrow

**Reducing action of amalgams. II. A theory of the amalgam surface.** Kurô Masuda. *J. Chem. Soc. Japan* 54, 558-65(1933); cf. *C. A.* 27, 5620.—The reducing action of Zn amalgam can be expressed by the no. of  $H_2$  bubbles formed at the contact surface between  $H_2SO_4$  and the amalgam under a certain condition. T. Katsurai

**Theory of overvoltage.** O. A. Esin. *Z. physik. Chem.* A166, 270-2(1933).—The theory of Erdey-Gruz and Volmer (*C. A.* 25, 452) on H overvoltage explains most of the exptl. data without further assumptions if one considers the rate of the back reaction. G. M. M.

**Dependence on concentration of the Volta potentials in the systems  $Ag/Ag^+$  and  $Cu/Cu^+$ .** M. Andauer and E. Lange. *Z. physik. Chem.* A166, 219-27(1933).—The ionization method was used to investigate the dependence of Volta potential on concn. in the system  $Ag/Ag^+$  from 0.1 to  $10^{-9}$  M Ag-ion concn. The potential of the surface layer changes only by about 0.01 v. for a 10-fold change in the concn. of the Ag-ion. A few preliminary expts. were also made in Cu soln. G. M. M.

**The isothermal equilibrium,  $CaCO_3 + NH_4NO_3$ , aq.** A. Guyer and H. Schütze. *Helv. Chim. Acta* 16, 904-13(1933).—The soly. of  $CaCO_3$  in  $NH_4NO_3$  solns. was detd. for the temp. range 25-45°. By use of the simplified expression for the equil. const.,  $K = [Ca^{++}]^2/[NH_4^+][H_2O]$ , it was shown that the soly. is due to the  $H^+$  ions from the  $HNO_3$  formed by the hydrolysis of  $NH_4NO_3$ .

**Graphic representation of chemical equilibrium.** Pierre Jolibois. *Compt. rend.* 197, 451(1933).—J. cites an earlier paper (*C. A.* 23, 2636) in which a graphic method of representation of chem. equil. was used to calc. the disson. of  $CO_2$ . The remarks by Etienne (*C. A.* 27, 5624) were generalized by Montagne (*C. A.* 27, 2866).

**Active oxides. LXVII. Aluminum oxides and their addition products with water.** (A contribution to the thermodynamics of equilibria in systems with two solid basic compounds.) Gustav F. Hüttig and Franz Kölbl. *Z. anorg. allgem. Chem.* 214, 289-306(1933); cf. *C. A.* 27, 3415.—Isobaric dehydration and hydration curves were detd. for hydrated gels and *bohmite*, *bayerite* and *hydrargillite* in the crystal. hydrates of the  $\gamma$  series and for  $\gamma$  Al oxides, such as *diaspore*. The thermodynamic relationship between experimentally observed equil. and the equil. calcd. from thermodynamic data in the systems  $XV_{solid} + X_{solid} + Y_{gaseous}$  is discussed. H. S.

**A calculation of the equilibria in keto-enol tautomerism.** G. W. Wheland. *J. Chem. Phys.* 1, 731-6(1933).—The equilibria obtaining in some simple cases of keto-enol tautomerism were calcd. with the aid of bond and resonance energies derived from empirical data. The results obtained are in qual. and semi-quant. agreement with expt. Morris Muskat

**The equilibrium of manganese and phosphorus in the light of recent temperature measurements. II.** Carl Schwarz. *Arch. Eisenhüttenw.* 7, 223-7(1933); cf. *C. A.* 27, 5693.—A previously developed formula is modified to give more exact values of equil. for Mn and P when the content of  $P_2O_5$  is high; also, the basicity and the ratio of Mn:Fe are taken into account. The new formula is  $\log K_{Mn} = \log [(Fe) \cdot (Mn)] \times Mn = -(5920/T) - (0.332 T/1000) + 1.778 B (0.956 - B) + 3.0243$ . Nomograms on the basis of this formula are given. Ten references. M. Hartenheim

**Effect of supersonic waves on chemical phenomena. I.** Nofuo Moriguchi. *J. Chem. Soc. Japan* 54, 949-57(1933).—The effect of supersonic waves on heterogeneous reactions was studied. The formation of  $H_2$  in the reactions  $Zn + HCl$ ,  $Zn + H_2SO_4$ , and that of  $CO_2$  in the reaction  $CaCO_3 + HCl$  was markedly promoted by supersonic waves. T. Katsurai

**Action of chlorine water on silver nitrate: kinetic study.** M. L. Josien. *Compt. rend.* 197, 449 50(1933).—The oxidizing power of a soln. of Cl in water after the Cl ion is removed by  $AgNO_3$  is the same as in the Cl water before pptn. If a  $AgNO_3$  soln. is added, drop by drop, to Cl water (test excess by  $K_2CrO_4$ ) a color change occurs when the amt. of  $AgNO_3$  added is equiv. to half the original amt. of Cl. If the  $AgNO_3$  soln. is poured into the Cl water rapidly in the case of an older soln. the same color change occurs ( $K_2CrO_4$ ). The second step consists of  $3HClO = HClO_3 + 2HCl$ , and an addnl. quantity of  $AgCl$  is thrown down. Dilm. retards and increased temp. accelerates the formation of chloric acid. Thus the slow addn. of  $AgNO_3$  to Cl water ppt. half the Cl, while  $AgNO_3$  poured rapidly into Cl water ppt. 5/6 of the Cl.

H. E. Messmore

**Recombination of the hydrogen atoms in the technical tungsten arc.** F. J. Havlicek. *Izv. Phys. Acad. 6*, 165-97 (1933).—The recombination of at. H of high pressure (1 atm.) is found to be monomol. The velocity of reaction increases with temp. The mean life at ordinary temp. is about  $10^{-10}$  sec. The expts. were made with streaming H contg. about 50% at. H, which combines in a calorimeter contg. Pt asbestos as catalyst. E. B.

**Effect of hydrogen chloride on propyl alcohol. Relation between rate of reaction and the electrostatic activity.** S. Kilpi. *Z. physik. Chem.* A166, 285-301 (1933). The rates of the reaction between HCl and PrOH and the hydrolysis of PrCl were studied. The change of the rate of the reaction with the electrolyte concn. was compared with the change of the activity of the HCl calcd. according to the Gronwall, LaMer and Sandved extension of the Debye-Hückel theory (C. A. 22, 3334). The change of the rate with change of solvent was also studied. The change of rate with temp. as well as the activation energy and the action const. of the reaction were calcd.

**Raising of the lifetime of  $\beta$ -phenyl- $\beta$ -chloroethylamine on charcoal.** H. Freundlich and G. Salomon. *Z. physik. Chem.* A166, 179-204 (1933); cf. C. A. 24, 3487. The kinetics of the reaction:

was studied on blood charcoal.

**Two problems connected with the method of investigation of saline equilibria.** V. P. Shishokun. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 21-4 (1933); cf. C. A. 21, 3802. The problem of detg. the no. of solid phases in a system consisting of a liquid solvent and a solute of 2 substances in a state of solid soln. is discussed together with the problem of detg. the amt. of soln. impregnating a cryst. mass in contact with its soln. S. L. Madorsky

**The cooling of blocks in molds, especially of brass blocks in water-cooled molds.** Walter Roth. *Giesserei* 20, 413-19 (1933).—A math. discussion of thermal cond. is given. Under rapid cooling a 70-30 brass solidifies at const. temp., and not over a temp. interval, as would be expected from the equil. diagram. C. L. W.

**Solubility of silicon in aluminum in the solid state at various temperatures.** P. Ya. Saldan and M. V. Danilovich. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 81-9 (1933).—Solv. curves of Si in Al in solid state were detd. for the temp. interval 15-560°. It was found that in the interval room temp. to 300° soly. is const. and is 0.09% by wt. of Si. From 300° to 400° soly. gradually increases up to 0.3%. Above 400° it increases rapidly up to 0.48% at 480°, and to 1.25% at 560°. By extrapolating the soly. curve up to the eutectic point at 570°, the limiting soly. is found to be 1.32% by wt. Si. S. L. Madorsky

**Solubility curve of copper in aluminum in the solid state.** P. Ya. Saldan and N. G. Anisimov. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 69-77 (1933); cf. C. A. 21, 3801; 24, 4742. S. L. Madorsky

**Singular points in fusion curves.** A. B. Mlodzevskii. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 5-12 (1933); cf. C. A. 23, 3148.—Math. S. L. Madorsky

**Fusion curves of solid solutions with formation of chemical compounds.** A. B. Mlodzevskii. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 13-20 (1933); cf. C. A. 26, 24.—Math. S. L. Madorsky

**Binary systems in two phases (1) HCl-Kr, (2) HCl-C<sub>2</sub>H<sub>4</sub>.** George Glockler, Donald L. Juller and Charles P. Row. *J. Chem. Phys.* 1, 714-16 (1933).—The P-T-X relations of the binary mixts. HCl-Kr and HCl-C<sub>2</sub>H<sub>4</sub> were detd. Retrograde condensation was observed with all mixts. studied. Not more than 1 liquid phase was found for any of the mixts. Morris Muskat

**An investigation of the thermal expansion of the double system Na<sub>2</sub>B<sub>2</sub>O<sub>7</sub>-B<sub>2</sub>O<sub>3</sub> in molten state.** M. P. Volarovich. *Bull. acad. sci. U. R. S. S., Classe sci. math. nat.* 1933, 663-74.—The dilatometric method was used for measuring the sp. vol. of molten glass up to 1400°, and consisted in measuring the level of the molten glass, contained in a

test-tube shaped Pt vessel, by means of elec. contact with a Pt rod. Sp. vols. of Na<sub>2</sub>B<sub>2</sub>O<sub>7</sub>, B<sub>2</sub>O<sub>3</sub> and of binary mixts. contg. 74, 59.5 and 20% Na<sub>2</sub>B<sub>2</sub>O<sub>7</sub> were measured through the interval 500-1300°. The expansion coeffs. obtained are in satisfactory agreement with those of Samson. With B<sub>2</sub>O<sub>3</sub>, the expansion coeff. reaches a max. at about the m. p., then gradually decreases. Results confirm Batzchinski's formula  $v = \omega + (c/\eta)$ , where  $\eta$  = viscosity,  $v$  = sp. vol. and  $c$  and  $\omega$  are const., for a certain range of temp. At high temps., the relation between  $\eta$  and  $v$  is linear. At lower temps. variation from linearity is considerable, which can be accounted for by polymerization. Isothermal curves for  $v$  plotted against percentage compn., show that mixing Na<sub>2</sub>B<sub>2</sub>O<sub>7</sub> with Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> is accompanied by considerable contraction with eventual increase in viscosity. S. L. Madorsky

**Vapor tension in the systems: sodium sulfate-water and sodium carbonate-water.** E. Ya. Rode. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 97-134 (1933).—Vapor-tension curves were detd. for a series of temps. (5° to 51°) for the following systems: Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O soln. vapor; Na<sub>2</sub>SO<sub>4</sub>-soln. vapor; Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O-Na<sub>2</sub>SO<sub>4</sub> vapor; Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O-soln. vapor; Na<sub>2</sub>CO<sub>3</sub>·7H<sub>2</sub>O-soln. vapor; Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O-soln. vapor; Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O-Na<sub>2</sub>CO<sub>3</sub>·7H<sub>2</sub>O-vapor; Na<sub>2</sub>CO<sub>3</sub>·7H<sub>2</sub>O-Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O-vapor; Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O-Na<sub>2</sub>CO<sub>3</sub> vapor. Isotherms of dehydration of Na<sub>2</sub>SO<sub>4</sub> and Na<sub>2</sub>CO<sub>3</sub> were detd. at 15° and 25°. The exptl. results were used for detg. transition points in these systems and for a theoretical calcn. of heats of hydration of these salts at various temps. Calcd. results are in good agreement with the exptl. S. L. Madorsky

**Thermal analysis of the system lithium fluoride-lithium metaborate.** I. I. Kitaigorodskii, T. A. Popova and O. K. Botvinkin. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 135-9; *J. Phys. Chem.* (U. S. S. R.) 4, 380-2 (1933).—A thermal investigation of the system LiF-LiBO<sub>2</sub> was undertaken with the object of finding a glass capable of transmitting ultra-violet rays. The melting diagram contains a max. corresponding to the complex compd. 2LiF·LiBO<sub>2</sub>. Two polymorphic transformations in this compd., at 515° and 585°, were detd., also 2 in LiF, at 812° and 762°, and 1 in LiBO<sub>2</sub> at 785°. Eutectics were found at 688° for LiF-2LiF·3LiBO<sub>2</sub>, contg. 66% LiBO<sub>2</sub>, and at 710° for LiBO<sub>2</sub>-2LiF·3LiBO<sub>2</sub>, contg. 80% LiBO<sub>2</sub>. S. L. Madorsky

**Solubility of potassium acid phosphate in the presence of phosphoric acid, potassium hydroxide and potassium chloride.** A. I. Krasilshelkov. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 159-68 (1933). That part of the system K<sub>2</sub>O-P<sub>2</sub>O<sub>5</sub>-H<sub>2</sub>O was investigated which corresponds to the solid phase KH<sub>2</sub>PO<sub>4</sub>, in order to find out to what extent the soly. isotherms of KH<sub>2</sub>PO<sub>4</sub> belong to the singular type of isotherms discovered by Kurnakov for compds. which are non-dissoc. either in the liquid or solid phase. The K<sub>2</sub>HPO<sub>4</sub> reacts with free H<sub>3</sub>PO<sub>4</sub> and with KOH forming KH<sub>2</sub>PO<sub>4</sub>·H<sub>3</sub>PO<sub>4</sub> and K<sub>2</sub>HPO<sub>4</sub>, both of which are more sol. than KH<sub>2</sub>PO<sub>4</sub> and, therefore, soly. isotherms of KH<sub>2</sub>PO<sub>4</sub> form the so-called anticlinical folds. The systems K<sub>2</sub>O-P<sub>2</sub>O<sub>5</sub>-H<sub>2</sub>O and KH<sub>2</sub>PO<sub>4</sub>-KCl-H<sub>2</sub>O were investigated at 0°, 25° and 50°, and the system K<sub>2</sub>O-P<sub>2</sub>O<sub>5</sub>-KCl-H<sub>2</sub>O at 25°. The solubilities of KH<sub>2</sub>PO<sub>4</sub> in H<sub>2</sub>O are 12.70, 19.42 and 29.1% wt. at 0°, 25° and 50°. At 25° the soly. of KH<sub>2</sub>PO<sub>4</sub> in satd. soln. of KCl is 32.9 mols. per 1000 mols. H<sub>2</sub>O, while the soly. of KCl in satd. soln. of KH<sub>2</sub>PO<sub>4</sub> is 83.9 as compared with 86.8 mols. per 1000 mols. in pure H<sub>2</sub>O. The addn. of free H<sub>3</sub>PO<sub>4</sub> or KOH lowers to a considerable extent the soly. of KCl and increases the soly. of KH<sub>2</sub>PO<sub>4</sub>. S. L. M.

**Ternary system ammonia-nitrogen pentoxide-water.** N. S. Kurnakov and M. I. Ravich. *Ann. inst. anal. phys.-chim.* (Leningrad) 6, 169-84 (1933); cf. C. A. 26, 3720.—Isotherms for the ternary system NH<sub>3</sub>:N<sub>2</sub>O<sub>5</sub>:H<sub>2</sub>O were detd. at -10°, 0°, 25°, 35°, 55°, 80°, 80°, 100° and 130°. The isotherm at 130° was detd. by keeping the soln. in a sealed tube. S. L. Madorsky

**Electrochemical properties of the triple system iodine-water-sodium iodide.** A. N. Strelnikov. *Bull. acad. sci. U. R. S. S., Classe sci. math. nat.* 1933, 715-28.—Satn.

curves of I in aq. solns. of NaI contg. 0.21-04.86 salt satn. and satn. curves of NaI in I solns. of various concns. are given. The sp. cond. curve for satd. solns. of I in aq. solns. of NaI shows a max. at 50.09% NaI satn. Sp. cond. measurements of various concns. of I in satd. soln. of NaI show some increase in cond. because of the I, probably because of the dissoec. effect of the I on the salt. E. m. f. values between any one of the metals: Mg, Al, Zn, Fe, Cd, Ni, Pb, Cu, Ag and Sn on one side, and Pt on the other, in an electrolyte contg. 12.90%  $\text{H}_2\text{O}$ , 63.28% I and 23.82% NaI, were detd. S. L. M.

**The homogeneous catalysis of gaseous reactions by iodine. The decomposition of propionaldehyde and a general discussion.** S. Bairstow and C. N. Hinshelwood. *Proc. Roy. Soc. (London)* A142, 77-88(1933).—The rate of the homogeneous decompu.  $\text{C}_3\text{H}_7\text{CHO} = \text{C}_2\text{H}_4 + \text{CO}$  is increased about  $10^4$  times by 7 mm. of  $\text{I}_2$ ; the rate of reaction is proportional to the concn. of the  $\text{I}_2$  catalyst. The kinetics of the process indicate that the  $\text{C}_3\text{H}_7\text{CHO}$  mols. exert a deactivating effect on the I-aldehyde complex. The energy of activation is 32,800 cal. In general the energies of activation of such reactions catalyzed by  $\text{I}_2$  are very much lower than those of the uncatalyzed reactions and this energy instead of being distributed through the whole mol. appears to be placed in a part of the mol. where it can be efficiently used in breaking the bond. The existence of a dipole moment in or near the bond broken suggests that the selective energy transfers are favored by polarization and attraction of the I. mol. P. H. Emmett.

**The action of inhibitors.** K. Bodendorf. *Ber.* 66B, 1608 11(1933); cf. C. A. 27, 4472.—In the autoxidation of  $\text{BzH}$ , *m*- and *p*- $\text{C}_6\text{H}_4(\text{OH})_2$  are powerful inhibitors and their di-Me ethers are moderately strong, but their diacetates have almost no effect, in agreement with Staudinger's observations (C. A. 8, 685) of the relative rates of oxidation of  $\text{BzH}$  and its  $\text{OH}$ ,  $\text{OMe}$  and  $\text{OAc}$  derivs. In Eder's soln. the phenols and their di-Me ethers act as above, but in  $\alpha$ -terpinene the phenols are only moderately active and the ethers have no effect.

H. A. Beatty

**Homogeneous catalysis of the para-ortho-hydrogen conversion under the influence of paramagnetic molecules.** I. L. Farkas and H. Sachsse. *Z. physik. Chem.* B23, 1 18(1933); cf. C. A. 27, 3874.—The reaction: para  $\text{H}_2 \rightleftharpoons \text{X} \rightleftharpoons \text{ortho H}_2 + \text{X}$  was studied where  $\text{X} = \text{O}_2$ ,  $\text{NO}$  and  $\text{NO}_2$  at temps. of 77.3-77.3°, 143-793° and 293-373° abs., resp. The reaction rate consts. are, resp., 2.16, 31.9 and 12.5 l./mol., min. at 293° abs. The collision yield does not change much with temp. but it agrees well with the theory of Wigner as does also the abs. rate (cf. below). In the solvents  $\text{H}_2\text{O}$ ,  $\text{PhNH}_2$ ,  $\text{PhH}$ ,  $\text{MeOH}$  and cyclohexanol the rate is about  $5 \times 10^{-6}$  smaller than in the gas reaction and the conversion is ascribed to the effect of the nuclear moment of the H atom in the solvent. II. *Ibid.* 19-27.—The paramagnetic ions Zn, Cu, Ni, Co, Fe, Mn, Pr, Nd, Sm, Gd, Er and Yb catalyze the para-ortho-H conversion in the same way that mols. do. The rate is proportional to the square of the magnetic moment of the ions. Dissolved O gives about the same rate as O does in the gas state.

G. M. Murphy

**Paramagnetic conversion of para-ortho hydrogen.** III. I. Wigner. *Z. physik. Chem.* B23, 28-32(1933); cf. preceding abstr.—The collision yield in the conversion of ortho- into para- $\text{H}_2$  and the reverse reaction are inversely proportional to the abs. temp. and directly proportional to the square of the magnetic moment. G. M. M.

**Chemical inertia and heterogeneous catalysis.** M. Lemaire. *Chimie & Industrie Special No.*, 747 51 (June, 1933); cf. C. A. 26, 5480. Conclusions: The chem. inertia exhibited by 2 substances, one of which is solid and the other gaseous, is due to the fact that the heat generated by superficial attack of the solid suppresses adsorption, and consequently the contact between the substances, thus preventing further reaction. This impossibility of reaction is complete if the film formed is impermeable to the gas; it is transient and periodic if

the film is permeable. There is no inertia if the reaction product has a b. p. so low that it is volatilized by the heat generated. From a discussion of the application of this theory to the action of catalysts, it is concluded that a solid can act as catalyst only provided it adsorbs gases efficiently; its efficiency as a catalyst is reduced in proportion to the degree to which it can react exothermically with one of the gases present in the mixt. to be catalyzed.

A. Papineau-Couture

**Promoter action in the catalytic decomposition of sodium hypochlorite solutions.** IV. John R. Lewis and Francis Seegmiller. *J. Phys. Chem.* 37, 917-21(1933); cf. C. A. 25, 4773.—The promoter effect of  $\text{CaO}$ ,  $\text{CdO}$ ,  $\text{HgO}$ ,  $\text{MgO}$ ,  $\text{BaO}$ ,  $\text{BaCO}_3$ ,  $\text{BaC}_2\text{O}_4$ ,  $\text{BaCr}_2\text{O}_7$ ,  $\text{BaSO}_4$ ,  $\text{CaCO}_3$ , and  $\text{CaC}_2\text{O}_4$  in the  $\text{CuO}$  catalysis of  $\text{NaClO}$  was studied. Max. promotion is obtained at various ratios of promoter to catalyst; no relation exists between cryst. structure of a promoter and its activity. E. G. V. B.

**The sorption of oxygen by nickel catalysts.** W. Walker Russell and Leonard G. Ghering. *J. Am. Chem. Soc.* 55, 4468 71(1933).—Large vols. of  $\text{O}_2$  were instantaneously and irreversibly adsorbed by catalytically active Ni even at  $-190^\circ$ ; a slower irreversible adsorption also occurred, the extent and rate of which increased with temp. over the range  $-190$  to  $23^\circ$ . A considerable amt. of reversible adsorption occurred at  $-190^\circ$  and decreased rapidly in amt. with increasing temp. Apparently, activated adsorption of  $\text{O}_2$  occurs instantaneously and rapidly even at  $-190^\circ$  on active Ni surfaces.

P. H. Emmett

**Benzene synthesis from carbon monoxide and hydrogen at ordinary pressure.** XII. Cobalt-copper-thorium-uranium catalysts. XIII. Nickel catalysts (1). XIV. Nickel catalysts (2). Kenji Fujimura and Shunzo Tsunekawa. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 22, 198 201, 242 7, 248 53(1933).—See C. A. 27, 16, 3133. XV, XVI. Nickel catalysts. *Ibid.* 254-8, 259-63. —See C. A. 27, 4997. G. G.

**General investigation of the activity of a catalyst.** E. Rosenkranz. *Chimie & Industrie Special No.*, 755-6 (June, 1933); cf. C. A. 26, 663. Catalysts obtained by the decompu. of a chem. compd. were studied. A decompu. of the type: crystal  $\rightarrow$  crystal<sub>2</sub> + gas, must be considered as a dissoen. resulting from a superposed partial reactions, to which are due the activity and characteristics of the final product. It can be shown that for each catalyst intended to accelerate a specific reaction obtained by such a decompu., there is a certain time of dissoen. during which activity is max. A. P.-C.

**Relation between active adsorption centers and catalytic activity. Measurements on active iron.** R. Klar. *Z. physik. Chem.* A166, 273 84(1933).—The adsorption of  $\text{C}_2\text{H}_4$ ,  $\text{C}_2\text{H}_2$  and  $\text{H}$  on Fe preps. of various activities was studied. From the results the no. of active centers was calcd. and their properties were discussed.

G. M. Murphy

**Catalysts.** Paul Sabatier. *Chimie & Industrie Special No.*, 868(June, 1933).—The essential factor in catalysis must be the formation of an unstable compd. between the catalyst and one of the elements of the system, e. g.,  $\text{Ni}$  hydride in hydrogenation in the presence of  $\text{Ni}$ . Recent observations of the diffraction of electrons appear to confirm the existence of such a hydride. A. P.-C.

**Theory of thermal conduction.** B. Bružs. *Z. Physik* 83, 513-53(1933).—A new principle in thermodynamics is suggested, according to which the properties of a system in a stationary state (such as a const. heat current) depend only on the properties of the system in thermal equil.

R. Pierls

**Heat dissipation of heated wires and pipes in a current of air.** R. Hilpert. *Forsch. Gebiete Ingenieurw.* A or B, 4, 215-25(1933).—Work is reported on the amt. of heat dissipated from a wire or pipe in a current of air. The wires and the tubes used were circular in cross section with diams. of 0.0198-150 mm. Air velocities varied from 2 to 30 m. per sec. Reynold's no. for these conditions ranged between 2.1 and 231,000. Hexagonal and square cross sections were studied with Reynold's no. from 5000

to 100,000. Nusselt's function ( $Nu$ ) is related to Reynold's no. ( $Re$ ) by the expression  $Nu = c(Re)^m$ , where  $c$  and  $m$  are consts. with special values for various ranges of Reynold's no. Heat from a wire at 1000° is about 6% greater than the heat given off at 100°. The exptl. work can be represented by the equation:

$$Nu = c_1 \left( \frac{Re(T_w)^{1/4}}{(T_w)} \right)^m$$

where  $Nu$  = Nusselt's function,  $c_1$  = const.,  $Re$  Reynold's no.,  $T_w$  = surface temp.,  $T_a$  = air temp.

M. C. ROBERTS

**Remark on the article by H. Kuhn and S. Arrhenius: "Determination of the heat of dissociation of the cadmium molecule by a thermooptical method."** A. Jablonski. *Z. Physik* 85, 268 (1933). A correction of an error. Cf. C. 1. 27, 1158. E. B.

**Energy of formation of aluminum oxide from the ele**

**ments.** W. D. Treadwell and L. Terebesi. *Helv. Chim. Acta* 16, 922-39 (1933).—The heat of formation of  $Al_2O_3$  was calcd. up to 2600°K. by means of the third law of thermodynamics and found to be in accord with exptl. data. For 298.1°K. it is 371,100 cal. These calcd. values were checked as follows: For the temp. range 380-460°K. by means of the  $Cl-Al$  cell and the equil.,  $AlO_3 + 6HCl \rightleftharpoons 2AlCl_3 + 3H_2O$ ; for 1120-1380°K. by means of the  $O-Al$  cell; and for 1930-2160° by means of the  $CO$  tension over  $Al_2O_3-C$  mixts. J. H. Reedy

**Spectrum physics and thermodynamics. The calculation of free energies, entropies, specific heats and equilibria from spectroscopic data, and the validity of the third law II. Some selected cases and principles** H. Zula. *Z. Elektrochem.* 39, 895-909 (1933); cf. C. 1. 27, 1919. Review — G. G.

**Terpenes, sesquiterpenes and their related compds.** (Uchida, Shunoyama) 10.

### 5—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERTI NOYTS, JR

**Critical observations on the evaluation of measurements on the charge of small particles.** A. Lustig and M. Reiss. *Z. Physik* 84, 131-5 (1933).—L. and R. maintain that there is no exptl. evidence showing definitely that there is no charge smaller than that of the electron. R. P.

**Conditions for the existence of the Ramsauer effect** Wilhelm Voss. *Z. Physik* 83, 581-618 (1933). The sharp max. in the scattering of electrons by atoms as a function of their energy is due to a competition between the elec. forces attracting the electron to the atom and the centrifugal force. The position of the max. and its approx. height can easily be calcd. from this picture. R. Peierls

**Visual observation of interferences of slow cathode rays.** W. Ischnberg. *Naturwissenschaften* 21, 673 (1933). R. J. C. van der Hoeven

**Scattering of electrons by heavy atoms.** Walter Henneberg. *Z. Physik* 83, 555-80 (1933). The field of the atom has been approximated by Fermi's field, the wave function of the electron has been calcd. by the method of Wentzel-Kramers-Brillouin. The calcd. scattering is in very good agreement with expts. of F. L. Arnot and others. R. Peierls

**The anomalous reflection of fast electrons from the surfaces of single crystals.** II. Seishi Kikuchi and Shigeo Nakagawa. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 21, 256-65 (1933); cf. C. 1. 27, 1975. At certain azimuths, 40-100 kv. electrons produce diffraction images not in accord with the Bragg relation. The discrepancies are of 2 kinds: supernumerary maxima and doubling of predicted maxima. K. and N. suggest that these results, as well as the anomalous dispersion mentioned by Davisson and Germer and the anomalous behavior of the  $P$ -line observed by Shinohara, are explicable on the ground that the reflectors behave simultaneously as two- and three-dimensional lattices. It is consequently not justifiable to assume a const.  $n$ . Bethe's theory predicts values for the width of the maxima which are too small. Calvin Brous

**Structure of thin celluloid films.** E. Taylor Jones. *Phil. Mag.* 16, 793-808 (1933). Electron diffraction photographs of nitrocellulose were obtained in which the pattern appears to be quadruple. This effect is ascribed to the formation of principal patterns in 2 parts of the film whose lattices are inclined at 67° to each other and of sec. patterns from thinner layers of different lattice dimensions inclined at nearly the same angle as the principal pattern. The patterns are explained in terms of a net of hexagonal rings of length 4.95 Å. U. and width 3.68 Å. U. The spacing between layers is 4.26 Å. U. The d. calcd. from the compn.  $C_6H_7O_2NO_2$  is 1.48 g./cc.; the observed d. is 1.33 g./cc. II. *Ibid.* 953-61.—Two addnl. electron diffraction patterns of celluloid are described

and explained in terms of lattice planes and spacings.

R. J. ROSENBAUM

**Thermionic work function and atomic distance.** W. Distler and G. Monch. *Z. Physik* 84, 271-5 (1933). The work functions for Ni and Fe have been found to be 4.63 and 4.04 v., resp. The first value is in agreement with a theoretical formula due to Schottky for the relation between work function and at. distance, while the second definitely is in disagreement with this formula. A discussion of the existing exptl. material gives no argument in favor of any existing theoretical formula. R. P.

**The long wave limit of cesium oxide cells.** J. P. Widmer. *Helv. Phys. Acta* 6, 269-70 (1933).—The sensitivity of Philips Cs photocells is small for wave length 1.1280  $\mu$ . The limit current for longer waves in the paper by de Boer and Leves (C. 1. 25, 1151) is due to scattered light. Egon Bretscher

**Energy levels of the hydrogen molecular ion.** C. Gilbert. *Phil. Mag.* 16, 529-44 (1933).—A perturbation theory is presented whose results agree with those of the variation method. Energy curves for the excited state of the  $H$  mol. ion are drawn. Exptl. values of the moment of inertia are smaller than the theory requires. R. J. ROSENBAUM

**Present state of our knowledge of the surface photoelectric effect.** W. Kluge. *Kinetech.* 14, 423-8 (1932). A review M. W. Seymour

**The external photoelectric effect of alkali halides.** R. Fleischmann. *Z. Physik* 84, 717-21 (1933). R. P.

**Inner potential of semiconductors.** K. R. Dixit. *Phil. Mag.* 16, 980-91 (1933).—The inner potentials of  $ZnS$ ,  $PbS$ ,  $FeS$ , and  $Fe_2O_3$  were detd. by the diffraction of fast electrons. The value found, which were checked by Kikuchi line measurements, are:  $ZnS$  4.8 v.,  $PbS$  2.5 v.,  $FeS$  5.1 v. and  $Fe_2O_3$  12.6 v. These values are in approx. agreement with those calcd. from an extended form of Bethe's equation for the potential of a crystal. The surface grating effect was observed. R. J. ROSENBAUM

**The nuclear distances of the mercury halides ( $HgI_2$ ,  $HgBr_2$ ,  $HgCl_2$ ).** H. Braune and S. Knoke. *Z. physik. Chem.* B23, 163-70 (1933).—Electron diffraction expts. were used to det. nuclear distances in  $HgI_2$ ,  $HgBr_2$ , and  $HgCl_2$ . G. M. Murphy

**Theory of atomic nuclei.** IV. E. N. Capon. *Z. Physik* 84, 509-19 (1933).—See C. A. 27, 3393. V. *Ibid.* 520-30. R. Peierls

**Interaction between neutrons and protons.** G. C. Wick. *Z. Physik* 84, 799-800 (1933).—Heisenberg's hypothesis on the nature of these interaction forces could be verified by measuring the angular distribution in the scattering of sufficiently fast neutrons by H. R. P.

**Scattering of neutrons by protons.** E. Wigner. *Z.*

*Physik* 83, 253 8(1933).—From the exptl. fact that the scattering is nearly isotropic one can obtain an upper limit for the distance up to which there are forces between the 2 particles. This in connection with the existence of a stationary state in which the particles are bound (deuteron) permits an est. of the scattering cross section which is confirmed by some of the existing exptl. figures. The expts., however, do not give consistent results.

R. Peierls

**The atomic weights of radioactive substances.** Forrest Western and Arthur E. Ruark. *J. Chem. Physics* 1, 717 22(1933).—At. wts. of the lead isotopes 206, 207 and 208 are obtained in 3 independent ways from chem. and mass-spectrograph data. They are: 205.98, 206.98 and 207.98  $\pm$  0.03. By adding the mass lost in disintegration in the form of  $\alpha$ - and  $\beta$ -particles and  $\gamma$ -rays, at. wts. of all known radioactive substances are obtained. Some results, correct to  $\pm$  0.03, are: Po, 209.99, Rn, 222.02, Ra, 226.02; M<sup>238</sup>Th, 228.03; Io, 230.03; Th, 232.03, Pa, 231.03, U<sup>235</sup>, 235.04, U<sup>238</sup>, 238.04, U<sup>234</sup>, 234.04. These data extend the packing-fraction curve to U. The following relation is approx. true:  $W/N = 0.02 + 0.00214(N - 200)$ , where  $W$  = at. wt. of a radioactive isotope and  $N$  = nearest integer. M. M.

**Artificial disintegration of magnesium with Po  $\alpha$ -rays.** W. Bothe and H. Klamann. *Naturwissenschaften* 21, 639 10(1933). A Rutherford Geiger counter tube was used to study the no. of protons emitted in a 90° direction by irradiation of Mg with Po  $\alpha$ -rays. Curves are given for the no. of protons per  $10^6$   $\alpha$ -particles vs. their range with 7 different  $\alpha$  range from 1.81 to 3.87 cm. In the 3.87 cm. curve 4 proton groups are found. Between 1.9 and 2.8 cm. only 1 group remains and it disappears for an  $\alpha$ -range of 1.5 cm. Evidently the Pose (C. A. 25, 248) resonance (on Al) for nuclear excitation is found here for Mg as well. The energy liberation range for all proton groups.

B. J. C. van der Hoeven

**Disintegration of atoms by cosmic rays and the positive electron.** Blackett and Occhialini. *Spektr. Fiz. Nauk.* 13, 491-517(1933). C. A. 27, 2874

F. H. Rathmann

**The weakening of the cosmic radiation when passing through different materials.** F. G. Stenke and H. Heich. *Z. Physik* 84, 125 9(1933).—The ratio of the weakening in Pb, Fe and Al corresponds approx. to the ratio of the no. of at. electrons. It is, therefore, not consistent with the assumption that also the nuclear electrons make a contribution of the same magnitude as the outer electrons.

R. Peierls

**Atom debris of low range from lithium and boron.** F. Knecht. *Naturwissenschaften* 21, 676(1933).—Photographs were made of fog chamber expts. on atom disintegration by canal rays (C. A. 27, 1729) on B, range 1.3 to 1.5 cm. The range was further extended downward by reducing the air equiv. of the sepp. wall between vacuum and chamber to less than 2 mm. For 15 mm. atoms debris traces were found of range 1-1.5 cm. (energy ( $\alpha$  particles) 2 million electron v. (cosmory 17 million). Signs were found of a faint group at 2 cm corresponding to the one found by Cockerill and Walton (C. A. 27, 1816). For B debris was traced down to a range of 6 mm, however of less intensity than that above 2 cm.

B. J. C. van der Hoeven

**The disintegration of the nuclei of nitrogen and other light atoms by neutrons.** I. Wm D. Harkins, David M. Gans and Henry W. Newson. *Phys. Rev.* 44, 529 37(1933). Thirty-one disintegrations of N were found in 6000 pairs of photographs of a Wilson chamber through which neutrons were shot from a Be-MsTh source. Of these, 19 were disintegrations in which the neutron was captured according to reaction

The no. of disintegrations shows a max. for neutrons of velocity  $3.2 \times 10^9$  cm/sec. The lowest velocity and highest velocity which produce such a disintegration are  $1.9 \times 10^9$  and  $5.5 \times 10^9$  cm./sec., resp. The form of the distribution curve is explained by the assumption

that the probability that a neutron will be effective in producing disintegration increases rapidly with its velocity, but that as the velocity considered lies higher and higher above  $3.2 \times 10^9$  cm./sec. the no. of neutrons present at such a velocity decreases rapidly. The highest energy found for a neutron at capture is  $15.8 \times 10^6$  electron v., while, according to theory, it should be  $14.7 \times 10^6$  provided the  $\alpha$ -particle comes from ThC'. Without exception, for every disintegration of an at. nucleus by capture of a neutron, kinetic energy is conserved or much more often disappears. It is assumed that this energy plus any energy in the form of mass which disappears is converted into  $\gamma$ -rays. The value obtained suggest that the spectrum of these rays is a line spectrum, which may be superimposed upon a continuous spectrum. Nine disintegrations of the N nucleus were obtained in which it is probable that either (a) the neutron was first reflected by a nucleus and later disintegrated a N nucleus with capture or (b) the neutron was not captured. Thirteen disintegrations of Ne nuclei in 5200 photographs and 2 disintegrations in ethylene are reported. The latter are presumably due to C nuclei but may be due to O of the H<sub>2</sub>O present.

Bernard Lewis

**Nuclear excitation by hard  $\gamma$ -rays.** Th. Heiting. *Naturwissenschaften* 21, 674(1933). Al, Fe, Cu and Pb are excited by the Th C'  $\gamma$  line of  $\lambda = 4.7$  X. units to nuclear radiation. This was studied for a scattering angle of 130° by the ionization method; correction was made for stray radiation of the (Pb) absorber. The  $E_\gamma$  found was for Al 0.519, for Fe 0.538, for Cu 0.567, for Pb 1.87 (all  $\times 10^6$  electron v.). The law of intensity of  $\gamma$  radiation proportional to the square of at. no. (Gray and Tarrant, C. A. 26, 1211) was well confirmed.

B. J. C. van der Hoeven

**Wilson chamber investigations of the wave radiation emitted by Ra D.** G. v. Droste zu Vischering. *Z. Physik* 84, 17 11(1933). The ranges and relative nos. of the various groups of electron tracks have been measured. One of these groups is due to photoelectrons from the direct  $\gamma$  rays, the second to the Compton electrons and the third to Bi L radiation excited when the  $\gamma$  quantum was caught in the L shell of the original atom. The ranges apply a check of the formulas for the dependence of range on energy; from the no. one can calc. the probability that the  $\gamma$  quantum is caught before leaving the atom of origin. The result is that only 3.6 out of 100 quanta will leave the atom.

R. Peierls

**Scattering of short wave  $\gamma$ -rays.** L. Meitner and H. Koster. *Z. Physik* 84, 137-44(1933).— $\gamma$ -Radiation of a mean wave length of 4.7 X. U. falls on a target of Fe or Pb. The radiation scattered under 90° is measured. It contains, aside from the Compton radiation, the wave length of which is much greater than the original one, a component with unmodified wave length. This result is in disagreement with the results of Gray and Tarrant (C. A. 26, 4211). It is pointed out that in connection with the creation of pos. electrons one ought to expect scattered light with unmodified wave length.

R. P.

**The exchange of hydrogen between water and hydrogen compounds dissolved in it.** K. F. Bonhoeffer and G. W. Brown. *Z. physik. Chem.* B23, 171-4(1933).—H<sub>2</sub>O contg. 1 part in 800 of H<sub>2</sub> was prepd. by the electrolysis of 150 l. of H<sub>2</sub>O from com. electrolytic cells with H<sub>2</sub>SO<sub>4</sub> as electrolyte and Pb electrodes. NH<sub>3</sub>, NH<sub>4</sub>Cl and cane sugar were dissolved in this water and by d. detn it was shown that the H<sub>2</sub> exchanged with H<sup>+</sup> contained in the compds.

G. M. Murphy

**Isotope of hydrogen of mass 2.** G. S. Landsberg. *Spektr. Fiz. Nauk.* 12, 313-8(1932).—Comments are made on the work of Urey, Brickwedde and Murphy (C. A. 26, 4212).

F. H. Rathmann

**The concentration of deuterium by electrolysis.** D. H. Rauk. *J. Chem. Physics* 1, 750 1(1933).—The concn. of deuterium by electrolysis is discussed and it is shown that the sepn. factor depends on the temp. at which the electrolysis takes place. It is concluded that com. cells which are run hot will have a low equil. concn. of deuterium

and that the  $I_{\beta}$  produced by such cells will have a low concn. of the heavier isotope. M. M.

**Detection of radioactivity in the S Stefano D'Istria hot sulfur spring.** Mario Picotti. *Boll. soc. ital. sper.* **40**, 665-7(1933). The water has a radioactivity of 8 milli-microcuries per l. The "half-period" is 4 days. Peter Masucci

**Radioactivity of natural brines of the Ural region, Gorki District and Bashkir Republic.** B. A. Nikitin and P. V. Myatelnin. *Bull. Acad. sci. U. R. S. S. Classe sci. math. nat.* **1933**, 675-81. Brines obtained near Balakhash (Gorki District) and Krasnoursk (Bashkir Republic) contain Ra and Rn. These brines are related in their chem. compn. to the petroleum waters contg. Ra, but unlike these, do not contain appreciable amts. of I. Balakhash brines seem to be in contact with bitumens. Brines obtained near Solikamsk and Bereznikov (Ural Region) are by their chem. compn. and genesis unlike Ra-carrying waters and are not radioactive. S. L. Madorsky

**The radium industry in Portugal.** Charles Lepicre and A. Pio Leite. *Chimie Et industrie Special No.*, 797-801(June, 1933). A description of the Ra-bearing deposits in the Guarda and Vizeu districts of Portugal. The acid, alk. and mixed acid-alk. processes of attacking the ore are briefly outlined. A. Papineau Couture

**The existence of time lags in the Faraday effect.** J. S. Webb and D. R. Morev. *Phys. Rev.* **44**, 589-601(1933). The nature of the initial or surge currents, and of the oscillatory currents, found in a magneto-optic app. similar to that used by P. Allison, has been investigated. Conclusion. The cause of the results of Allison is not a time lag in the Faraday effect but is some, as yet, unknown cause, possibly a peculiar sort of Kerr phenomenon. Bernard Lewis

**Magnetorotation with non-adiabatic variation of the magnetic field.** Egon Bretschner and Walter Deek. *Helv. Phys. Acta* **6**, 229-31(1933). Magnetorotation in a high-frequency magnetic field is treated theoretically and experimentally to det. whether a relaxation occurs when the frequency of the magnetic field is larger than the Larmor frequency of the corresponding Zeeman effect. A beam of light was sent through Na vapor contained in an absorption tube and a high-frequency magnetic field was applied in the direction of the beam. The light used was polarized by a Nicol prism and a second Nicol prism after the tube acted as analyzer. The light intensity after the analyzer was detd. as a function of the field frequency, the amplitude of the magnetic field remaining const. In agreement with theory no sign of inertia of the Faraday effect was found. Egon Bretschner

**The L, M and N absorption in the region of ultra-soft x-rays.** J. A. Prins and A. J. Takens. *Z. Physik* **84**, 65-74(1933); cf. *C. A.* **27**, 4166. R. Peierls

**Precision measurements in the L-series of the elements molybdenum and silver.** Philip Haglund. *Z. Physik* **84**, 248-59(1933). R. Peierls

**The L x-ray spectrum of solid aluminum.** T. H. Osgood. *Phys. Rev.* **44**, 517-19(1933).—The L x-ray spectrum of solid Al consists, not of sharp lines, but of a wide continuous band of radiation extending between the approx. limits 170 and 200 A. U. This is in agreement with the Pauli-Sommerfeld theory of free electrons in metals. Bernard Lewis

**Quadrupole transitions and other faint lines in the K spectra of the elements 37 rubidium to 42 molybdenum.** H. Erik Carlsson. *Z. Physik* **84**, 119-30(1933); cf. *C. A.* **27**, 2092. A new spectrometer, combined with x-ray tube, and contg. a curved crystal, has been constructed for this purpose, and several weak lines of Mo, 9 Cb, Zr, Yt, Sr and Rb have been found and discussed. R. Peierls

**Thermal and röntgenographic characterization of lattice distortions in zinc oxide.** R. Fricke and P. Aeltermann. *Z. anorg. allgem. Chem.* **214**, 177-88(1933); cf. *C. A.* **27**, 1980. Below 600°, ZnO, prepd. from rhombic crystal  $Zn(OH)_2$ , shows a higher energy content the lower the temp. of formation, and the shorter the

period of formation. The indicated excess in total energy in the youngest prepn. amounts to 1.3 kg. cal./mol. The x-ray investigations indicate that this excess energy is dependent upon an incomplete lattice formation. The presence of another modification or of distorted lattices may be inferred. No certain evidence has been obtained as yet from line broadening. C. J. Humphreys

**The thermal expansion of quartz by x-ray measurements.** A. H. Jay. *Proc. Roy. Soc. A* **142**, 237-47(1933); cf. *C. A.* **27**, 4458, 5220. —The lattice spacings for clear colorless quartz were detd. for various temps. between 18° and 730 by powder photograms. A temp. scale for the camera was obtained from the lattice expansion of silver (cf. Jay, *Z. Krist.* **86**, 150(1933)). The  $\alpha, \beta$ -transformation point was found at 579°. The expansion laws for the  $a$  and  $c$  axes were found identical with those found by optical methods. Victor Hicks

**Anomalies in the regular reflection and diffraction of molecular beams by crystal surfaces.** I. R. Frisch and O. Stern. *Z. Physik* **84**, 430-42(1933).—The reflection curves for mol. beams by crystal surfaces show strange minima which are probably connected with the adsorption of the mols. to the surface. II. R. Frisch. *Ibid.* **443** 7. The described effect has been studied in detail. Each of these anomalous minima occurs, when 2 components of the velocity of the outgoing particle have certain values. It seems, therefore, that mols. can most easily be adsorbed if 2 components of their velocity relative to the surface have given values. R. Peierls

**Chemical action of x-rays.** Paul Gunther. *Angew. Chem.* **46**, 627-31(1933). A discussion of chem. action of x-rays in the light of the quantum theory and a review of the literature. Twenty-seven references. K. K.

**Multiplet separations and perturbed terms.** N. G. Whitelaw. *Phys. Rev.* **44**, 54-50(1933). B. L.

**The quantum defect of nonpenetrating orbits, with special application to Al II.** J. D. Van Vleck and N. G. Whitelaw. *Phys. Rev.* **44**, 551-69(1933). B. L.

**The nuclear spin of  $Li^7$  from hyperfine structure data.** Newton M. Gray. *Phys. Rev.* **44**, 570-4(1933). Bernard Lewis

**Hyperfine structure in the arc spectrum of fluorine.** J. Stuart Campbell. *Z. Physik* **84**, 393-401(1933).—Measurements of hyperfine structure lead definitely to the assumption of a spin of  $1/2$  for the F nucleus. The magnetic moment is slightly smaller than that of the Br nucleus. R. Peierls

**Nuclear spin of arsenic.** A. S. Rao. *Z. Physik* **84**, 236-17(1933); cf. *C. A.* **27**, 2093. —Measurements of the hyperfine structure in As II confirm Tolansky's value  $1/2$  for the nuclear spin and the structures of the lines investigated by Tolansky. More lines have been studied and the new material leads to some changes in the interpretation of terms. With these new interpretations the selection and interval rules and the intensities are in accord with theoretical predictions. R. P.

**The magnetic transformation of hyperfine structure in mercury.** D. R. Inglis. *Z. Physik* **84**, 460-73(1933).—Simplified formulas for the Paschen-Back effect in this special case are given. R. Peierls

**Paschen-Back effects in the spectra of thallium.** A. M. Crooker. *Phil. Mag.* **16**, 994-1005(1933).—The Paschen-Back effect for the  $\Gamma$  lines of wave lengths 3776, 5362 and 5949 A. U. was studied with a 3-m. grating at a field strength of 25.3 kilogausses. The observed patterns agree well with those deduced from the theory of Goudsmit and Bacher, showing the absence of perturbation effects. E. J. Rosenbaum

**Term tables for the atomic spectra of carbon, nitrogen and oxygen.** Bengt Edlén. *Z. Physik* **84**, 746-66(1933).—Tables are given contg. all known terms in the spectra C I, C II, C III, C IV, N II, N III, N IV, N V, O II, O III, O IV, O V, O VI. R. Peierls

**Experiments to extend the helium spectrum by exciting both electrons.** A. H. Rosenthal. *Z. Physik* **84**, 794-8(1933). The expts. were unsuccessful. R. P.

**Wave mechanical calculation of the Rydberg corrections for helium.** Egil A. Hylleraas. *Z. Physik* 83, 730-64 (1933).—The calcn. of the terms of the He atom has been improved, by extending the method in such a way as to give account of the polarization forces (i. e., the change of the distribution of one electron connected with the change of state of the other). R. Peierls

**The continuous absorption spectrum of helium.** J. P. Vinti. *Phys. Rev.* 44, 524-8 (1933). B. I.

**Isotope shift in neon.** J. H. Bartlett, Jr. and J. J. Gibbins, Jr. *Phys. Rev.* 44, 538-43 (1933).—The theory of isotopic displacement due to the motion of the nucleus has been extended to atoms with any no. of electrons (Russell-Saunders coupling being assumed) and applied to the transitions  $2p^2s$   $2p^2p$  in Ne. Approx. Hartree wave functions have been obtained and orthogonalized. The theory gives a shift in singlet states of  $0.0195 \text{ cm}^{-1}$  more than that in triplet states, as against approx.  $0.017 \text{ cm}^{-1}$  measured by Nagaoka and Mishima (*C. A.* 24, 4985). However, the calcd. shift for the singlet transition is  $0.0038 \text{ cm}^{-1}$  as against the exptl. value of  $0.0332 \text{ cm}^{-1}$ . This discrepancy may disappear if better wave functions are found. Bernard Lewis

**The lowest excited states of neon according to Slater's method.** St. Rozental. *Z. Physik* 83, 534-42 (1933).—The energy values have been calcd. by using approx. expressions for the wave functions, and give fairly good agreement with the exptl. values. R. Peierls

**The spectrum of doubly ionized argon.** A. III. V. v. Keussler. *Z. Physik* 84, 42-55 (1933).—Several lines of the term system with the limit  $4s$  have been found and analyzed. Their comparison with the spectra S I and Cl II suggest some changes in the quantum nos. usually ascribed to the terms of S I. The third ionization potential of A is  $40.7 \text{ v}$ . R. Peierls

**The primed terms in the spectra of alkaline earths** H. C. Brinkman. *Z. Physik* 83, 259-65 (1933).—By using theoretical relations between the terms of a spectrum contg. two-valence electrons, one term in each of the spectra of Ca, Sr and Ba could be identified. Predictions as to the probable positions of other terms with the same electronic configuration have been obtained. R. Peierls

**Polarization of fluorescent light of pure mercury vapor** A. Kastler. *Compt. rend.* 197, 412-4 (1933). When Hg vapor is illuminated with rays contg. light of 2537 and 4358 Å. U., fluorescent rays of 4358 and 4046 Å. U. observed in a direction normal to the incident rays should be polarized and the planes of vibration at right angles to one another. The state of polarization of a fluorescent ray is defined by the degree of polarization  $P = I + i, I - i$ . For 4358 Å. U.  $P$  should equal  $+1$ , for 4046 Å. U.  $P$  should equal  $-1$ . Two images are seen on the photographic plate; the ray 4358 Å. is polarized positively and the ray 4046 Å. negatively. These 2 rays are incompletely polarized. By diminishing the aperture of the incident ray, lowering the temp. of the fluorescence chamber and by rectifying the terrestrial field by a magnetic field parallel to the incident ray the degree of polarization of the 2 rays agrees in value. H. E. M.

**The series  $1S_0 - m^1P_1$  and  $1S_0 - m^3P_1$  in the arc spectrum of mercury and their perturbing term  $1P_1(5d)^0$  ( $1s^2(6p)$ ).** H. Beutler. *Z. Physik* 84, 289-303 (1933). New measurements of these series have been made. As the series do not follow Rydberg's formula, they must be perturbed by a configuration having energy which is not very different. A new assumption as to the position of this perturbing term is discussed. R. Peierls

**Shifting and asymmetrical widening of absorption lines by foreign gases.** Chr. Fichtbauer and F. Gössler. *Naturwissenschaften* 21, 675-6 (1933).—Widening of spectral lines by foreign gases has been described previously C. I. 17, 2830; Meier, Diss. Rostock 1925; cf. C. A. 21, 1063; Margenau and Watson, *C. A.* 27, 5245; Minkowski, *C. A.* 24, 1794). The Cs lines 4555 and 850 were studied in the presence of pure He, Ne, A and  $N_2$  of  $4 \frac{1}{2}$  atm. pressure, temp.  $125^\circ$  and  $180^\circ$ . The line shifting is proportional to the pressure (table),

toward violet as well as toward red; in 2 cases the direction is different for the 2 lines (C. A. 27, 4731). On going over to a line higher in the series violet asymmetry becomes more pronounced (He); faint red asymmetry changes into violet (Ne and  $N_2$ ); strong red asymmetry weakens slightly (A). All disturbances tend to increase for the higher members in the series.

B. J. C. van der Hoeven

**A new method for the detection of metastable atoms.** A. Buhl. *Helv. Phys. Acta* 6, 231-3 (1933).—The atoms of a beam of Hg are partly excited to the metastable state by electron collision and the charged particles are removed by an elec. field. The atom beam falls on a W wire activated with O and heated to about  $1500^\circ$ . As the work function of the activated W is 5.40 v. and the ionization potential of Hg atoms in the  $^1I_1$  state only 4.95 v. Hg<sup>+</sup> ions are formed on the W surface which are collected on an electrode and their no. deduced from the current. A rough estn. shows that only 1 atom among 30,000 is in the metastable state. Leon Bretscher

**Quantum mechanics of the anharmonic oscillator.** G. Poschl and E. Teller. *Z. Physik* 83, 143-51 (1933).—If the energy values (band spectrum) of an oscillating system (mol.) are known, one cannot draw an unambiguous conclusion on the potential curve, as there are always many different curves giving rise to the same energy values. The relations between these different curves are slightly different from the old quantum theory. Several typical examples are given. R. Peierls

**Dissociation of diatomic molecules with the  $p$ - $p$  bond.** H. Lassheim and R. Samuel. *Z. Physik* 84, 637-656 (1933).—Discussion of several examples of mols., where the electrons which are responsible for the binding forces, are in at.  $p$ -states (non-vanishing angular momentum). In several cases the correspondence between mol. and at. states which is suggested here differs from the usual one. One of the new principles introduced in order to set up this correspondence means that if an unsatd. electron is present, which does not contribute to the binding, the disson. energy will be increased by exciting this electron into a higher level. By this method one has more freedom in ascribing at. states to the disson. limits of band series and better coincidence between the at. energy differences and the frequencies of the band limits can be obtained. Conclusion: The calcn. of these limits from spectroscopic data is more accurate than generally assumed. R. Peierls

**Character of the linkage in hydrogen halides on the basis of absolute intensity measurements of the infra-red fundamental vibration bands.** E. Bartholomé. *Z. Physik. Chem.* B23, 131-51 (1933).—A method is described for measuring the abs. intensity of infra-red vibration bands. The results for HCl, HBr and HI give the transition probability,  $B_0 = 1.93, 1.67$  and  $0.35 \times 10^{18}$ , resp., and the effective charge,  $0.086, 0.075$  and  $0.0336$ , resp. The latter values are so small that they indicate homeopolar linkage in the halides. G. M. Murphy

**The heats of dissociation of hydrogen and nitrogen.** W. Wallace Lozier. *Phys. Rev.* 44, 575-81 (1933).—A method previously described (Lozier, *C. A.* 25, 3550) has been used to det. the heats of disson. of normal mol. and the mol. ion for  $H_2$  and  $N_2$ . The new app. is made of Ta. Electrons passing through diat. gases are able to produce at. ions possessing kinetic energies of several v. Simultaneous measurements of the electron energy necessary to produce at. ions and the kinetic energy of the ions permit the detn. of the heats of disson. The values found are  $D(H_2^+) = 2.59 \pm 0.03 \text{ v.}$ ,  $D(H_2) = 4.43 \pm 0.03 \text{ v.}$ ,  $D(N_2^+) = 6.73 \pm 0.02 \text{ v.}$ ,  $D(N_2) = 7.90 \pm 0.02 \text{ v.}$  These results are free from systematic errors to  $\pm 0.1 \text{ v.}$  These data are compared with the results of other methods, mainly spectroscopic. B. I.

**A band spectrum of barium hydride.** G. Funke. *Z. Physik* 84, 610-28 (1933).—The band spectrum of BaH between 5950 and 7500 Å. U. has been measured and analyzed. R. Peierls

**Intensity distribution and width of some AIE lines showing predissociation.** L. Farkas and S. Levy. *Z.*

*Physik* **84**, 195-207(1933). Width and intensity distribution of several lines showing predissociation have been measured as functions of the rotational quantum no.

R. Peierls

**The band spectrum of copper hydride.** All Heimer and Tage Heimer. *Z. Physik* **84**, 222-35(1933).—By making one electrode of an arc of C, the other of a Bi-Cu alloy, one can obtain the CuH bands. By this method several new band systems were found.

R. Peierls

**The so-called second positive group in the nitrogen spectrum.** D. Coster, F. Brion, and A. van der Ziel. *Z. Physik* **84**, 301-31(1933). Measurements.

R. P.

**A new band system of beryllium oxide and the structure of the beryllium oxide molecule.** Lause Herzberg. *Z. Physik* **84**, 571-92(1933). A new band system of this mol. has been found which extends from the red to the near infra-red. It has been measured and analyzed and the potential curves for the corresponding term of the mol. have been constructed.

R. Peierls

**Spectroscopic evidence for the molecule PN.** J. Curry, L. Herzberg and H. Herzberg. *J. Chem. Physics* **1**, 749(1933).—A new band system discovered in gas discharges of mixts. of H<sub>2</sub> and P is shown to be due to the PN mol. The heads of 21 bands of the system are closely represented by the formula  $\nu = 39699.3 + (1094.75 v' - 7.25 v'^2) + (1329.38 v'' - 6.98 v''^2)$ , a preliminary rotational analysis giving:  $B'' = 0.48 \text{ cm}^{-1}$ ,  $B_0'' = 0.73 \text{ cm}^{-1}$ ;  $r_0'' = 1.49 \text{ \AA}$ ;  $r' = 1.51 \text{ \AA}$ . The system is due to a  $\Sigma \rightarrow \Sigma$  transition, the  $\Sigma$  state probably being the ground state of the mol.

M. M.

**Band spectra of indium chloride.** I. Miescher and M. Wehrh. *Helv. Phys. Acta* **6**, 256-9(1933). Band spectra of InCl are observed in the region 2600-7000 Å. U. (I) and 3300-3700 Å. U. (II). The band heads in (I) have been fitted to a formula.

Egon Bretscher

**Absorption of light by ozone between 3050 and 2150 Å. U.** Tsi Ze Ny and Shun-Piao Choong. *Compt. rend.* **196**, 916-18(1933). An extension of the table mentioned in C. A. **26**, 5008.

A. L. Hanna

**Extension of the ultra violet absorption spectrum of ozone toward the long wave lengths.** D. Chalouge and Mue. L. Uchelye. *Compt. rend.* **197**, 111-7(1933). O<sub>3</sub> is prepd. by the use of 2 Berthelot type ozonizers, having the form of a Dewar flask 28 cm. deep by 40 mm. in diam. Two tubes, then external faces covered with Sn, are connected to the secondary poles of a Rochford coil, the interrupter being of the revolving Hg type. The 2 ozonizers operate in series and are cooled to -80° with CO<sub>2</sub> and acetone. The ozone is sep'd by plunging the tube into liquid O<sub>2</sub>, the O<sub>3</sub> condensing to a blue liquid. The liquid O<sub>3</sub> is allowed to vaporize in a tube 2.45 m. in length and the gas, very rich in O<sub>3</sub>, has an intense violet-blue tint. A spectroscopic detn. gave 22° O<sub>3</sub>. The coeff. of absorption is of the order of 0.0025 for 3618 Å. U.

H. B. Mesmore

**Structure and Zeeman effect of the CO doublet emission bands at 2900 Å. U.** R. Schmid. *Z. Physik* **83**, 711-38(1933).

R. Peierls

**The double band at 3660 Å. U. in the spectrum of carbon dioxide.** R. Schmid. *Z. Physik* **84**, 732-9(1933).

R. Peierls

**The vibrational structure of the spectrum of carbon tetrachloride.** J. Hornich. *Z. Physik* **84**, 380-92(1933).—This spectrum shows a case of accidental resonance, as the sum of 2 fundamental frequencies is nearly equal to the third one. In such a case there will be a splitting of the vibrational lines. This splitting has been calculated and compared with observation.

R. P.

**Measurements on the rotational spectrum of water vapor.** Joachim Kulne. *Z. Physik* **84**, 722-31(1933). With a new type of vacuum spectrometer for the infra-red all water lines given by Rubens (cf. C. A. **11**, 1357) could be reproduced and a no. of new lines have been given.

R. Peierls

**The absorption spectra of some hydrocarbons in the Schumann region.** E. P. Carr and H. Stuecklen. *Helv. Phys. Acta* **6**, 261-5(1933). The absorptions of heptane, heptane, 1 heptylene, 2-pentylene, 1-pentylene, trimethyl

ethylene and benzene were detd. in the Schumann region. The satd. hydrocarbons have an absorption max. at 1500 Å. U. which is shifted to 1750 if the compd. is not satd. These bands are without any structure and attributed to the C-C disson. A series of oscillation bands in the region of 2200-1800 Å. U. characteristic for each substance is found. They have no rotational structure. The first oscn. band for C<sub>2</sub>H<sub>6</sub> has 2 maxima at 1778 and 1805 Å. U. The oscillation spectra are more complicated.

Egon Bretscher

**The infra red spectra of propane and diacetylene.** E. Bartholomé. *Z. Physik Chem.* **B23**, 152-7(1933).—The infra-red spectra of C<sub>3</sub>H<sub>8</sub> and C<sub>4</sub>H<sub>2</sub> were obtained. For the latter, a linear mol. is indicated.

G. M. M.

**Magnetic investigation of one-electron bonds in compounds of the type of tellurium dimethyl dihalides.** S. S. Bhattacharya and T. K. Lahiri. *Z. Physik* **84**, 671-5(1933). These compds. cannot contain a bond due to one electron, because in that case they ought to be either paramagnetic, or their diamagnetic susceptibility ought to decrease with decreasing temp. This is not the case according to the authors.

R. Peierls

**Absorption of sodium chloride, potassium chloride and potassium iodide in the far ultra-violet.** Albert Smith. *Phys. Rev.* **44**, 520-3(1933).—By use of a normal incidence, concave-grating, vacuum spectrograph with a hot spark as light source, qual. absorption curves have been obtained for NaCl, KCl and KI between 190 Å. U. and 1550 Å. U. The absorbing film of the alkali halide was deposited directly onto the ruled surface of the grating. The portions of max. absorption as read from the 3 curves given, are: for NaCl, 655, 535, 350 and 890 Å. U.; for KCl, 705, 530, 320 and 1120 Å. U.; for KI, 825, 625 and 510 Å. U., all accurate to 6%. These results are at variance with early theoretical extrapolations from the known form of the dispersion curves for rock salt and sylvite in the near infra-red.

B. L.

**Dispersion measurements with potassium bromide and potassium iodide in the infra-red.** K. Korth. *Z. Physik* **84**, 677-85(1933). A new method has been developed for obtaining large salt crystals. With these dispersion measurements have been made.

R. P.

**The theory of coordination bonds. IV. Raman effect of some complex cyanides.** R. Sammel and Mohd. Jan Khan. *Z. Physik* **84**, 87-91(1933); cf. C. A. **28**, 42.—All investigated cyanides show one Raman line which S. and K. interpret as due to the oscillation of the C against N, while some of them show also a second line which is attributed to the oscillation of CN against the rest of the mol. This latter line appears to be present only in complexes with the coordination no. 6.

R. P.

**The reactions of the hydroxyl radical in the electrodeless discharge in water vapor.** W. H. Rodebush and M. H. Wahl. *J. Chem. Physics* **1**, 696-702(1933).—A study of the reactions occurring in the electrodeless discharge in water vapor showed consistently high yields of H<sub>2</sub>O<sub>2</sub>. On the basis of a study of a no. of sp. reactions and by a process of elimination it is suggested that the mechanism of the formation of the H<sub>2</sub>O<sub>2</sub> is a homogeneous bimol. condensation of the hydroxyl to H<sub>2</sub>O<sub>2</sub>. The spectrographic investigation of the electrodeless discharge revealed the presence of new bands with heads at 3564 and 3328 Å. U., which appear to be due to an ionized hydroxyl. These bands were also found in the condensed electrode discharge at low pressures, but were absent in the uncondensed electrode discharge.

M. M.

**Chemical action in the glow discharge. XI. The decomposition of nitrogen dioxide and the nitrogen dioxide equilibrium.** A. Keith Brewer and P. D. Kuerk. *J. Phys. Chem.* **37**, 889-96(1933); cf. C. A. **26**, 5497.—The decompn. of NO<sub>2</sub> in the glow discharge is shown to obey the electrochem. equivalence law given for other reactions already reported in the present series. NO<sup>+</sup>, N<sub>2</sub><sup>+</sup> and O<sub>2</sub><sup>+</sup> are equally capable of initiating the reaction. The M/N ratio is about 2. The decompn. has a strong neg. temp. coeff., the M/N ratio being 3 times as great at room temp. as at 225°. Equil. measured at room temp. after the decompn. had come to a steady

state corresponded to 1.6%  $\text{NO}_2$  when the pressure was 5–10 mm. **XII. The dissociation of ammonia.** J. W. Westhaver. *Ibid.* 897–906.— $\text{NH}_3$  decomposes into its elements in the glow discharge, some  $\text{N}_2\text{H}_4$  being formed in the pos. column but none in the neg. glow. The rate is proportional to the current but independent of pressure.  $\text{N}_2^+$ ,  $\text{O}_2^+$ ,  $\text{He}^+$ ,  $\text{A}^+$  and  $\text{Hg}^+$  catalyze the decompn. as well as  $\text{NH}_3^+$ ; only  $\text{H}_2^+$  ions are inert. The equil. in an  $\text{NH}_3$ –( $3\text{H}_2$ : $\text{N}_2$ ) mixt. corresponds to about 6%  $\text{NH}_3$  at room temp. The  $M/N$  ratio is between 0.5 and 1.0.

P. H. Emmett

**The triboluminescence of mercurous halides.** J. II Krepelka and D. F. Novotny. *Collection Czechoslov. Chem. Comm.* 59 367 82(1933).—See *C. A.* 27, 4482.

G. G.

**Photosynthesis of nitrogenous compounds.** L. N. Bhargava and N. R. Dhar. *J. Indian Chem. Soc.* 10, 453–8(1933).—Nicotine and  $\text{MeNH}_2$  can be obtained by the exposure of a 2% soln. of  $\text{CH}_2\text{O}$ , a small quantity of  $\text{NH}_3$  in the presence of a catalyst as  $\text{CuCO}_3$ ,  $\text{ZnO}$  or  $\text{TiO}_2$  to sunlight or radiations from a Hg-vapor lamp. The nicotine is sepd. from the hexamethylenetetramine by the soly. of its  $\text{HgCl}_2$  salt in dil.  $\text{HOAc}$ . No nicotine was obtained when the expts. were carried out in the dark. This evidence supports the view that the synthesis of nitrogenous compds. in nature is photochem. J. W.

**Energy transfers at surfaces.** VII. Photosensitized oxidation as the action of an active, metastable state of the oxygen molecule. II. Kautsky, H. de Bruijn, R. Nieuwirth and W. Baumeister. *Ber.* 66B, 1588 600 (1933), cf. *C.* 1, 26, 1486; 27, 1029.—Trypallavine (I), and leuco-malachite green (II) are adsorbed separately on  $\text{SiO}_2$  gel granules 1.5 and 0.15–0.3 mm., resp., in size which are then mixed and illuminated in  $\text{O}_2$ . Oxidation of II occurs only at  $\text{O}_2$  pressures below 0.004 mm., and is not due to diffusion of I or II or to  $\text{H}_2\text{O}$  or oxidation products of I. With I and II sepd. by several mm., there is no reaction; with both adsorbed on the same gel,

oxidation occurs even at 1 atm. of  $\text{O}_2$ . Conclusion: Illumination of I produces an active, metastable  $\text{O}$  mol., possibly in the  $^1\Sigma$  state.

H. A. Beatty

**Quantum theoretical contributions to the problem of aromatic and unsaturated compounds.** IV. Free radicals in organic chemistry. Erich Huckel. *Z. Physik* 83, 632 68(1933); cf. *C. A.* 26, 5826.—When considering the dissoen. of hexaphenylethane into triphenylmethyl as taking part in 2 steps, first breaking up the large mol. into 2 halves without changing the configuration of atoms within the halves, and then rearranging, the first step would require a very high energy. In order to explain the low dissoen. energy one has to show, therefore, that the second step contributes a considerable gain of energy. This, according to II., is due mainly to the interaction between the valence electrons, which, for a plane arrangement of the atoms, is more favorable than in the actual arrangement before the dissoen. The dissoen. energy can reach these low values only with compds. contg. aromatic and unsatd. bonds. The magnitude of the dissoen. energy is discussed.

R. Peierls

Lignin [spectrum of] (Hillmer) 10.

**Electron-emitting cathodes.** Cornelis Zwicker (to Radio Corp. of America). U. S. 1,931,974, Oct. 24. An electron-emitting cathode of high electron emissivity at a working temp. of about  $1000^\circ$  comprises a metal coat such as Zn and Al alloy which at such a working temp. has a neg. resistance coeff. and a sp. heat about 20-fold the normal value, with a coating of an oxide such as that of an alk. earth metal having high electron emissivity at the working temp.

**Luminous compositions.** Richard Werner. Ger. 582,401, Nov. 2, 1933. A rare earth is sintered with  $\text{SiO}_2$  or a silicate or an alk. earth carbonat., and the product is comminuted. Examples are given.

## 4 – ELECTROCHEMISTRY

COLIN G. FINK

**Graphical method for determining the power factor of an electric furnace under varying working conditions.** C. Fous. *J. four élec.* 42, 311 16(1933).—Simple calcns. from graphic data are presented. Inductance is assumed to be const., and the power factor independent of current.

C. F. Bonilla

**Casting special electric steels in the Marcinelle (Belgium) steel works.** E. Decherf. *J. four élec.* 42, 317 23(1933).—Many cast steels have been developed to replace more expensive ones and those difficult to forge: (1) C steel, 0.7% Mn, 0.3% Si, 68 kg./sq. cm. tensile strength; (2) 14% Mn steel, 1.4% C, good wearing qualities, preferable to converter steel (they can be improved by Cr or Mo addns.); (3) Ni-Cr-Mo steels, preferable to the usual Ni-Cr steels; high wearing resistance, resilience, good machinability, 105 kg./sq. cm. tensile strength (they can be welded); (4) a special 24% Cr steel for temp. up to  $1100^\circ$ ; (5) also very pure cast irons. Many photomicrographs are included. C. F. B.

**Electric-furnace manganese steel castings.** M. Salomon. *J. four élec.* 42, 324–6(1933).—The elec. furnace is preferable for hard, wear-resisting Mn steel castings, and is the only means of almost completely removing S. General advice is given on the steps in casting, melting, pouring, heat treating the castings and finishing them.

C. F. Bonilla

**The three-phase electric arc furnace.** Samuel Arnold, 3d. *Elec. Eng.* 52, 839–43(1933).—A review. C. G. F.

**Scientific control of electric arc furnaces.** E. Decherf. *J. four élec.* 42, 282–8(1933).—D. discusses application of semi-slow and slow melting to the manuf. of Ni-Cr steels. The latter requires more energy, but improves phys. properties. Time vs. voltage and power are given in graphical form for typical cases. C. F. Bonilla

**Carbon shapes for linings of electric melting and reducing furnaces.** C. Kuhlmann. *J. four élec.* 42, 289–91(1933).—Except for steel furnaces, C is the best lining, for chem. and phys. reasons. Cracks unpreventable in lining are healed with a mixt. of C scrap, tar, etc., and baked in place. Pre-baked forms do not shrink and have long life. They are also good in cells for production of Al by the Hall process. C. F. Bonilla

**Transformers for electric furnaces.** H. O. Stephens and L. S. Schell, Jr. *Elec. Eng.* 52, 822 6(1933).—The extremely high secondary currents and low secondary voltages, together with the wide variation in voltage required by many elec. furnaces, demand special design considerations in both the transformer and its assoc. equipment. C. G. F.

**Dephosphorization of Thomas steel in the electric furnace.** P. Girod. *J. four élec.* 42, 281(1933).—

Rapid dephosphorization of high-P steel (0.08%) to 0.015% P is possible at low temp. with a basic oxidizing flux of lime and hematite, together with a fluxing agent, such as soda ash, feldspar or fluorspar. At the same time oxidation of Fe is minimized. C. F. Bonilla

**Combined operation of converter and electric furnace.** A. Kayl. *J. four élec.* 42, 359 62(1933).—K. claims 250% daily capacity increase, reduced energy consumption, and better cast steel by making these steps immediately consecutive. The required change to a basic converter lining and the furnace and converter operation are described. C. F. Bonilla

**Conductivity of slags in the electric furnace.** Axel Wejnarth. *Arch. Erzbergbau Erzaufbereit. Metallhüttenw.* 1, 191–208(1931).—In order of decreasing effectiveness, the following constituent lower the elec. cond. of silicate slags:  $\text{Al}_2\text{O}_3$ ,  $\text{CaO}$ ,  $\text{SiO}_2$ ,  $\text{FeO}$ , and  $\text{MnO}$  more strongly,

raises the cond. With rising temp. cond. increases, the coeff. being smaller with FeO and MnO than with CaO and  $\text{Al}_2\text{O}_3$  silicates. No definite relation was found between cond. and viscosity of the systems FeO-SiO<sub>2</sub>, FeO-CaO-SiO<sub>2</sub>, and FeO-CaO-MnO- $\text{Al}_2\text{O}_3$ -SiO<sub>2</sub>. Cond. is both metallic and electrolytic; the relative proportion of each depends upon composition of slag. Slags from numerous electrothermal processes show great variation in compn. Energy relationships in the slag bath are extremely complicated, partly because of a flaming arc which is influenced by c. d. and the form of electrode, and partly because of varying temps. of and near the electrode. Each process requires a specific voltage, charge, depth of bath, and operation. John G. Attwood

**Economical muffle-furnace operation.** C. G. Harrel and Stener Duos. *Cereal Chem.* 10, 452-56(1933).—It is pointed out that rheostat control of muffle furnaces is expensive on account of the current consumed by the rheostat. With a c. a. transformer may be used at a large saving in cost. With d. c. a high-temp. thermostat may be used. L. H. Bailey

**Smelting sponge iron in electric and open hearth furnaces at a German plant.** Ya. Granikov. *Dokl. Akad. Nauk SSSR*, No. 7, 29-42. Sponge iron prep'd. at the Bokunsk exptl. plant was smelted in an elec. and in an acid open-hearth furnace. Compn. of sponge: C 1.07, SiO<sub>2</sub> 0.6, Mn 0.1, P 0.01, S 0.027, Fe 75.2, Fe<sub>2</sub>O<sub>3</sub> 10.0, FeO 8.8 and CaO +  $\text{Al}_2\text{O}_3$  4.1%. This sponge was used with and without deoxidizers as part of the charge in the prep'n. of Cr-W-V tool-steels and plain steels. For comparison, melts were prep'd without the addn. of sponge. No tech. difficulties were encountered in the operation of the furnaces when sponge was used, and the products were of good grade. S. L. Madorsky

**Electrodes—carbon and graphite.** Frank J. Vosburgh. *Elect. Eng.* 52, 844-8(1933).—A review. C. G. F.

**The steel-melting coreless induction furnace.** M. Marchbanks. *J. Inst. Elec. Engrs.* (London) 73, 509-20 (1933).—A quite thorough description is given of construction and performance of this type of furnace, particularly of  $\frac{1}{4}$  ton capacity. Metallurgical refining action and math. theory of operation are also given. C. F. B.

**Copper electrolysis.** E. Vuigner. *J. four élec.* 42, 363-7(1933).—A general discussion of the acid sulfate bath. Max. efficiency and purity of cathode are obtained by using: anodes at least 99.25% pure; highly coned free acid, about 150 g./l.; temp. at least 40°; pure starting sheets; absence of colloidal addn. agents or chlorides. C. F. Bonilla

**The electrolysis of barium chloride without a diaphragm.** I. S. Katsen. *J. Chem. Ind.* (Moscow) 1933, No. 4, 34-41.—To get ClO ions in ordinary electrolysis of a soln. of BaCl<sub>2</sub>, 45% of the current is wasted in the production of Cl<sub>2</sub>. Cr and its compds. fail to prevent this. Best ClO efficiencies are obtained with graphite electrodes and a relatively high c. d. with a soln. contg. 1% CaCl<sub>2</sub> kept at 70°. Addn. of 1% gum arabic causes rapid evolution of Cl<sub>2</sub>. H. M. Leicester

**Electrolytic refining of mercury.** E. Newbery and S. M. Naude. *Metal Ind.* (London) 43, 415-18(1933).—See C. A. 27, 4175-6. G. G.

**Electrolytic deposits on aluminum.** H. Krause. *Mitt. Forschungsinst. Probant Edelmetalle* 7, 87-9(1933).—The procedure of Ni plating of Al and Al alloys is discussed. The metal must first be degreased in a 90° hot soln. of 7.5-22.5 g. each of Na<sub>3</sub>PO<sub>4</sub> and Na<sub>2</sub>CO<sub>3</sub> per l. and, after rinsing in cold water, immersed in a 5% bath of HCl. The surface is then roughened in a sand blast, or better, in a pickling bath, to make the deposit adhere well. The Ni soln. consists of 150 g. Na<sub>2</sub>SO<sub>4</sub>, 77 g. MgSO<sub>4</sub>, 15 g. H<sub>2</sub>SO<sub>4</sub>, and 15 g. boric acid per l.; temp., 35°; c. d. 1.5-2.5 am.;  $\rho_n$  5.8-6. A min. thickness of 0.0125 mm. is recommended. Any other metal may be deposited on Ni; Zn and Cr may be deposited directly on Al; but Al is not suitable for further working. Behavior especially for articles which are

exposed to high temps.; gradually increase to 315° and hold this temp. for several hrs. M. H.

**The influence of the basis metal, in particular, nickel, upon the throwing power of the chrome-plating bath.** J. Korpium and Ernst Vogel. *Oberflächentechn.* 10, 243-4 (1933).—The inherent low throwing power (t. p.) of the Cr-plating bath has been remedied in various ways which are briefly reviewed. A method for detg. the t. p. is described and results are given for the improvement which is obtainable through the basis metal. M. Hartenheim

**The art of cadmium plating.** F. Pietrafesa and E. Lotti. *Met. ital.* 25, 167-73(1933). The best conditions for Cd plating have been found to be: c. d. 2 amps./sq. dm., temp. 20°. Bath compn. is: 0.75 N Cd (as Na<sub>2</sub>Cd(CN)<sub>4</sub>); 1 N free NaCN; 0.75 N NaCl; plus a small amt. of certain org. addn. agents to improve the quality of the deposit. A. W. Contiri

**The rate of growth of cathodic deposits.** A. Glazunov and J. Janoušek. *Chimie & industrie Special No.*, 739-42(June, 1933).—By following electrolysis under the microscope, it was observed that there are 2 rates of linear crystn. during the deposition of the metal on the cathode, that of growth perpendicular to the cathode and that of growth parallel to the cathode. A. Papineau-Couture

**Relationship between the direction of growth of the cathodic deposit and of the direction of the lines of electric force.** A. Glazunov and O. Rada. *Chimie & industrie Special No.*, 736-8(June, 1933).—By using shallow electrolytic tanks (3-5 mm. deep) in which were placed variously shaped obstacles, dendritic shaped cathodic deposits were obtained which followed the lines of elec. force. A. Papineau-Couture

**Heterogeneous chemical reactions in the silent electric discharge.** VI. Susumu Miyamoto. *J. Sci. Hiroshima Univ.* A3, 347-66(1933). See C. A. 27, 2630. G. G.

**Overvoltage.** M. Volmer. *Physik. Z. Sowjetunion* 4, 346-59(1933).—V. modifies Tafel's theory (*Z. physik. Chem.* 50, 611(1905)) by adding the concept of an activation energy necessary for the discharge of ions through the double layer. For metals other than those of the bc group, concn. polarization masks the ion-discharge effect. L. W. Elder

**Quantum mechanics and overvoltage.** R. W. Gurney. *Physik. Z. Sowjetunion* 4, 360-4(1933)(in English); cf. Bowden. *C. A.* 24, 299, 1039. The elec. double layer is transparent to an electron wave; hence the transfer of electrons to and from ions may occur at some distance from the electrode surface. Overvoltage facilitates such electron transfers. L. W. Elder

**The size of electrolytically generated gas bubbles.** B. Kabanov and A. Frumkin. *Z. physik. Chem.* A166, 316-17(1933); cf. C. A. 27, 5617. —A few addnl. remarks are made in connection with the work of Wark (*C. A.* 27, 4194). G. M. Murphy

**The effect of the internal resistance of the galvanic cell upon the measurement of the electromotive force of the cell, using the capillary electrometer, and means for correcting for this effect.** II. T. Ishino and H. Inagawa. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 571(1933); cf. C. A. 27, 4177. —The true e. m. f. of the cell is given by the formula  $e = E(n_1 - n_m)/n$ , where  $E$  is the e. m. f. of the standard cell,  $n$  = bridge reading with the standard cell only,  $n_1$  = bridge reading with the standard cell and the cell with large internal resistance connected in the same direction and  $n_m$  = the mean value of the bridge readings. The results calcd. by means of this formula completely coincided with the known applied e. m. f. Karl Kammermeyer

**The mechanism of electrolytic degreasing of metals.** B. Kabanov. *Kolloid-Z.* 65, 101-5(1933); cf. C. A. 26, 4996.

**Utilization of electrochemically produced oxide layers on aluminum (Eloxal process) for metal coloration and for electrolytic coatings.** G. Buchner. *Oberflächentechn.* 10, 233-4. A table is given showing the different colors which can be obtained by electrochemically produced

oxide layers on Al, silumin and lantal; gray, yellow, white and bluish tones can be produced by definite electrolyte and oxidation conditions. The oxide layers are good absorbers for fat-sol. and water-sol. org. colors, especially tar derivs.; the article is suspended as anode in different org. solns., a few of which are described. Either a. c. or d. c. may be used; special effects may be obtained by polarized high-frequency current, that is, an a. c. with a superimposed d. c. of such intensity that the resulting current is only on one side of the zero line. The oxidation process is a complicated chem., electrochem. and elec. process in which *Al hydroxide* is formed on the surface. M. Hartenheim

**The constitution of  $Ta_2O_5$  layers as anodes.** P. O. Schupp. *Z. Physik* 84, 412-24(1933).—A contribution to the problem of electrolytic rectifiers. A method is described by which the development of the layer in an early stage may be interrupted. The layer is very porous during the early stages but not so later. The effect on the theoretical interpretation is discussed. R. Peierls

**Research in liquid dielectrics.** W. F. Davidson and Thorstein Larsen. *Elec. Eng.* 52, 918-20(1933).—A review. A bibliography of recent periodical literature is appended. C. G. F.

**Improvements in impregnated paper.** D. W. Roper. *Elec. Eng.* 52, 920-3(1933).—A review. C. G. F.

**Improvements in solid dielectrics.** R. W. Atkinson. *Elec. Eng.* 52, 923-7(1933).—A review with a 4-year bibliography. C. G. F.

**Recent trend of the mercury rectifier.** T. Ippomatsu. *J. Inst. Elec. Engrs., Japan* 53, 709-13(1933).—Production statistics, constructional details and characteristics of operation are given. C. F. Bonilla

**Comparison between surface and space discharges.** S. Mochizuki. *J. Inst. Elec. Engrs., Japan* 53, 722-5(1933).—Photographs and plotted characteristics of positive impulse voltage discharges, along or through dielectrics, are given. C. F. Bonilla

**New compensation method for the exact measurement of high voltages.** E. Hess. *Z. Physik* 83, 698-700(1933).—With the electrostatic method, developed by H., voltages up to 1100 v. may be measured with an accuracy of 1 in 1000. The method might be extended to even higher voltages and higher accuracies. R. P.

**Fine dust from the electrical precipitators at the Vitkovice blast furnaces.** F. Wald. *Chimie & industrie Special No.*, 698 9(June, 1933).—The dust from the Cottrell-Muller precipitators contains as much as 25% ZnO, 15% PbO and 0.1-0.28% I. The chief sources of the I are Ostrava coal and Polish limonites. A. P.-C.

**New methods and apparatus for magnetic and electrical beneficiation.** B. Granigg. *Arch. Erzebergbau Erzaufbereitung. Metallhüttenw.* 1, 75-87(1931).—A spiral serving as 1 pole of an electromagnet revolves in a cylinder which forms the other pole. A field intensity of 12,000 lines of force per sq. cm. is developed in a lab. machine consuming less than 5 amp. Hematite, siderite, tetrahedrite, chalcocopyrite, chamoisite, limonite, pyrolusite, miter magnesite, gel magnesite, feldspar, scynite, leucite, nephelite, apatite, corundum, and pptd. silicic acid in sizes of 0-12 mm. were satisfactorily treated in this machine. A tube separator is described which is unusual in that the material passes through the inside of the tube, thus being aided by centrifugal force, which is important in the sizes treated: 8-80 mm. Solenoid, radial, and axial windings have been tried in com.-sized machines, in which siderite, limonite, serpentine, chamoisite and hematite were concd. Separators making use of magnetic cond., elec. cond., and dielec. const. of the mineral have all operated successfully as lab. machines. J. G. A.

**Static electricity in nature and industry.** Paul G. Guert. *Bur. Mines, Bull.* 368, 98 pp.(1933).—The literature on static electricity and its hazards is reviewed. Over 260 references are given. The industries concerned include Al, aviation, building, chem., cleaning and dyeing, cotton, grain, mining and handling coal, paper and printing, petroleum. S and sugar. Alden H. Emery

**Current distribution on a straight wire excited at the center. Its impedance at the feeding point.** Y. Kato. *J. Inst. Elec. Engrs., Japan* 53, 746 9(1933).—Math. derivation. C. F. Bonilla

**Radiation power from conductors carrying current of steady flow.** G. Hata. *J. Inst. Elec. Engrs., Japan* 53, 750-6(1933).—Math. derivation for single conductors and groups. C. F. Bonilla

**Comparison of arc-extinguishing power of various anhydrous inorganic oxides.** S. Fukuda. *J. Inst. Elec. Engrs., Japan* 53, 729-33(1933).—The min. arc length that could be extinguished in  $1/2$  cycle was detd. for a cartridge fuse in terms of percentage packing of the arc space.  $B_2O_3$  is the best. C. F. Bonilla

**Magic with (ultra-violet) light.** Robert L. Zahour. *Elec. J.* 30, 453-6(1933).—After a brief review of the common source of ultra-violet light, a new "black bulb" lamp is described which emits 99% ultra-violet and 1% visible light. It operates at 5 amp. and 15 v. The source of light is a small Hg arc. C. G. F.

**Cl smelting with chloride electrolysis (Ashcroft) 9.** Exchange of H between  $H_2O$  and H compds. dissolved in it (Bonhoeffer, Brown) 3. New uses for thin films (Edwards) 9.  $II_2$  as a transmitter of energy (Voss) 13. Electrolytic bleaching of molasses (U. S. pat. 1,933,830) 16. App. for producing a hydrocarbon and metallic sol (U. S. pat. 1,933,836) 22. Alloy for storage-battery terminals (U. S. pat. 1,934,875) 9. App. (with spaced rotating electrodes) for effecting reactions (U. S. pat. 1,931,800) 18.

**Primary electric battery.** LeRoy S. Dunham (to Thomas A. Edison, Inc.). U. S. 1,932,654, Oct. 31. Structural features.

**Dry cell electric battery assembly.** Herman R. C. Anthony (to French Battery Co.). U. S. 1,932,128, Oct. 24. Structural details.

**Dry cells.** The Ever Ready Co. (Great Britain) Ltd. and Marcel Van Koningsveld. Brit. 396,521, Aug. 10, 1933. The dolly of a dry cell is insulated from the Zn cup by a member of paper, etc., having radial arms which are turned up when the dolly is inserted.

**Dry batteries.** Compagnie générale des piles wonder. Fr. 749,412, July 24, 1933. Construction of base to hold the depolarizing agglomerate in the center.

**High-tension battery provided with a flash-lamp bulb which serves as a fuse.** Wm. Fleet. Brit. 395,959, July 27, 1933.

**Galvanic cells.** Edouard Meier. Swiss 161,852, Aug. 1, 1933. A mech. appliance for preventing collection of gas bubbles in cells is described.

**Storage battery.** Bryan Merlan and John F. McClelland. U. S. 1,934,945, Nov. 14. Structural features.

**Positive storage battery plates.** Fred C. Perkins. U. S. 1,933,928, Nov. 7. Structural details.

**Battery cans.** Metallgesellschaft A.-G. Brit. 397,044, Aug. 17, 1933. Sheet Zn for battery cups is made by rolling plates cast at just above the m. p.; 420-425° is suitable, or even lower, if the Zn contains a small proportion of Pb.

**Accumulators.** The Chloride Electrical Storage Co. Ltd. and Herbert Dean. Brit. 395,488, July 20, 1933. An arrangement of glass plates for arresting spray is described.

**Accumulators.** Drumm Battery Co. Ltd. (formerly Celia Ltd.), James J. Drumm, Thomas Hagyard and Robert H. D. Barklie. Brit. 396,101, July 31, 1933. Addn. to 365,125 (C. A. 27, 2631) and 363,629 (C. A. 27, 5654). An accumulator in which Zn is deposited from an alk. electrolyte on charging is provided with a neg. electrode consisting of an alloy of Ni, Cr and Fe which is subjected to a pickling operation before use. A suitable alloy is Ni 35, Cr 5 and Fe 60%. The electrode may be heat-treated before pickling which may be effected by immersing in a soln. of HCl, HNO<sub>3</sub> and a restrainer comprising a mixt. of powd. glue, H<sub>2</sub>SO<sub>4</sub> and H<sub>2</sub>O or by anodic treatment in 10% HCl, the current d. being 300

milliamps. per sq. cm. The electrolyte contains 60 g. ZnO per l. KOH or may be prepd. by dissolving Zn in the a/k. soln.

**Accumulators.** Norman D. Sturges. Brit. 396,668, Aug. 10, 1933. The electrolyte in an accumulator is absorbed in bagasse which has been subjected to partial cooking to loosen the encrusting casing that surrounds the fibers but to retain the pith naturally present in the fibers. The cooling may be with a soln. of NaOH or in solns. of the sulfitcs or sulfates of the alkali metals.

**Accumulators.** Leonard A. Levy and Almeida Accumulators Ltd. Brit. 396,751, Aug. 9, 1933. An accumulator, in which Zn is deposited on charging, has pos. plates consisting of graphite surrounded by C granules or powder held together in plate form by gelatin, glue, etc., which dissolves in the electrolyte when the cell is assembled. The electrolyte contains  $ZnBr_2$ ,  $ZnCl_2$ , KOAc, LiCl or LiBr, and HCl.  $HgCl_2$  may be added to amalgamate the Zn and the Li salts may be replaced by the chlorides or bromides of Mg, Na and Be.

**Accumulators.** James Veith. Swiss 161,650, July 17, 1933. Electrodes for accumulators are made by spraying Pb on porous carriers. These may be previously treated with oxygenated Pb compds.

**Accumulators provided with specific gravity balls.** The Chloride Electrical Storage Co. Ltd. and Arthur W. Browne. Brit. 396,180, Aug. 3, 1933.

**Electrolytic condensers.** N. V. Philips' Gloeilampenfabrieken. Brit. 395,842, July 27, 1933. An electrolytic condenser has at least 1 fixed electrode, with a permanent oxide film, in the form of a rod having longitudinal ribs.

**Electric condensers.** Elektrizitäts-A.-G. Hydrowerk. Brit. 396,336, Aug. 3, 1933. A mixt. of castor oil and a solid or viscous material is used for impregnating the paper, etc., dielcc. of a condenser. A suitable compn. is castor oil 50%, the remainder being ozokerite, paraffin wax or a product of chloronaphthalene.

**Film formation on "valve metals" as in the production of electrolytic condensers.** Edgar W. Ingile (to Fansteel Products Co.). U. S. 1,935,395, Nov. 14. A metal plate such as Al is subjected to a.c. in an aq. electrolyte such as  $NaHCO_3$  soln., then to d.c. in an aq. electrolyte such as  $NaHCO_3$  soln., and finally to d.c. in a substantially dry glycerol soln. contg.  $NaHCO_3$ .

**Electrodeposition of metals.** Julius Winkler, Jr. Brit. 396,191, Aug. 3, 1933. In the deposition of 2 or more metals from a bath direct voltage, appropriate to each metal are applied in alternation for periods so short that the deposited layers have the characteristics of an alloy. 50-150 complete cycles per min. may be used. In an example an alloy contg. Au 69.5, Cu 28.2 and Ni 2.3% is deposited in a plating bath prepd. by treatment of an anode contg. Au 50.0, Cu 42.5 and Ni 7.5 in a bath contg. Na pyrophosphate 20, Na citrate 20, KCN 8 and  $H_2O$  1000 parts, an auxiliary cathode having half the surface of the anode being used and, when the bath contains 6 g. per l. of dissolved metal, replaced by the article to be plated. Sep. anodes of Au, Cu and Ni may be used.

**Electrodeposition of nickel.** Franz von Wursterberger. Brit. 395,979, July 27, 1933. Fe or steel, before plating with Ni, is anodically treated in  $H_2SO_4$  for passivation and slight etching. After brief rinsing it is plated in a bath contg. a Ni salt, a conducting salt, e. g.,  $MgSO_4$  or  $Na_2SO_4$ , a buffer acid, e. g.,  $H_3BO_3$ , and a tartrate, e. g.,  $NaK_2C_4H_4O_6$ , no adverse effects being produced with such a bath by Fe compds. unavoidably introduced by the preliminary treatment. Detailed examples are given.

**Zinc deposition from sulfate solutions.** Wm. H. Hannay and Frederick E. Lee (to Consolidated Mining and Smelting Co. of Canada Ltd.). U. S. 1,934,305, Nov. 7. A hydro-metallurgical method for the electrodeposition of Zn from a sulfate soln. comprises, when using a Pb anode in the electrolysis, the incorporation and maintenance in the soln. of 0.001-0.006 g. C<sub>60</sub> per l. of the soln. contg. about 10% of free acid, which serves to prevent corrosion and disintegration of the anode.

**Electroplating on aluminum and its alloys.** Siemens &

Halske A.-G. Brit. 394,637, June 29, 1933. Addn. to 385,067 (C. A. 27, 5257). The process of 385,067 is modified by producing the initial oxide coating by the use of a.c. in an alkali metal carbonate bath of low concn. free from Cl. The bath may contain 20-80 g.  $Na_2CO_3$  per l. The coated articles are subsequently treated as cathodes in a degreasing bath contg. Cu and Zn to effect first reduction of the coating and then deposition of brass. They are then rinsed and plated with the desired metal.

**Electroplating cadmium.** Roscoe Treats and Rudolph L. Hasche (to American Smelting & Refining Co.). U. S. 1,931,851, Oct. 24. Insol. anodes are used with a Cd sulfate electrolyte contg. a small proportion of saponin.

**Electroplating with tantalum.** Frank C. Driggs and Wm. C. Liffendahl (to Westinghouse Lamp Co.). U. S. 1,933,319, Oct. 31. An article to be plated such as one of Ni, Fe or Mo is immersed in a fused bath contg. alkali halide compds. such as KCl and KF together with an ionized Ta compd. such as K Ta fluoride and Ta oxide, and Ta is deposited as a continuous adherent coating by use of a c. d. of 1 to 10 amps. per sq. decimeter.

**Chromium-plating ferrous metals.** Stanley C. Moore and Frank E. Bowker (to Dura Co.). U. S. 1,931,704, Oct. 24. Articles of ferrous metal are successively coated with a metal such as Cd which is electronegative to Fe, with Ni and with Cr. Cu also may be used.

**Coating aluminum.** Aluminum Colors, Inc. Brit. 396,201, Aug. 3, 1933. White coatings are produced on Al (alloy) articles by forming an adherent oxide coating thereon by anodic treatment in a  $H_2SO_4$  or oxalic acid electrolyte and then, without the application of external elec. energy, removing the colored constituents of the coating with a suitable reagent, e. g.,  $H_2SO_4$  and (or)  $HNO_3$  or HF. Cf. C. A. 27, 2887.

**Coating aluminum.** Ernest Windsor-Bowen. Brit. 396,743, Aug. 8, 1933. In the anodic oxidation of Al (alloys) by d.c. or a.c. a bath contg.  $H_2SO_4$  and  $Na_2SO_4$  in the absence of Cl ions is used. An oxidizing agent, e. g., Na or K nitrate, persulfate or perborate, may be added in proportion of 1% or less. A  $H_2O$ -dispersible colloid may also be added, e. g., 25 parts of a 1% dispersion of gum to 75 parts electrolyte. Cf. C. A. 27, 5257.

**Locally strengthening electroplate deposits by means of stencils.** Hermann Kruger. Ger. 582,633, Aug. 18, 1933. Addn. to 576,099 (C. A. 27, 3674). Modifications in the method of Ger. 576,099 are described. Cf. C. A. 27, 3407.

**Electrolytic apparatus for depositing metals.** Copper Steel Co. Ger. 577,746, June 3, 1933.

**Electrolytic indicating and control apparatus.** Adolf Ufer (to Pioneer Instrument Co.). U. S. 1,932,329, Oct. 21. Structural and elec. features.

**Electrolysis of water.** Siemens & Halske A.-G. Fr. 750,002, Aug. 3, 1933. A series of U-shaped long metal pieces are assembled by the tie rods, with the branches turned outward and sepd. by insulating material, to form a body of elements open at the top, into which the electrodes may be inserted.

**Cobalt.** Soc. générale de constructions électriques et mécaniques (Als-Thom). Fr. 750,097, Aug. 3, 1933. Pure Co is obtained as a powder by electrolysis of a soln. of a Co salt, preferably pure sulfate, the density of the current is 500-5000 amps. per dm.<sup>2</sup> according to the size of grain desired and the temp. is 40-60°. Means is provided to remove the Co periodically from the cathode.

**White lead.** Horace G. Huls. U. S. 1,932,160, Oct. 24. Various structural details are described, of an app. for the electrolytic production of white lead.

**White lead by electrolysis.** Robert J. Frost. Ger. 586,065, Oct. 16, 1933. See Brit. 314,987 (C. A. 24, 1303).

**Alloy iron and steel.** Wm. B. Arnues (to Alloy Research Corp.). U. S. 1,932,252, Oct. 24. In the production of alloy iron and steel in an elec. arc furnace, there is added, to a ferrous metal bath, a reducible oxide such as Cr oxide and an amt. of a Si-contg. reducing agent such as ferro-Si in excess of the chem. equiv. of the oxide; also, a basic slag-forming material such as lime is added

in sufficient quantity to maintain basic conditions during reduction. Cf. C. A. 27, 5258.

**Rhodium.** Baker & Co., Inc. Fr. 749,846, July 29, 1933. Rh is deposited electrolytically from a soln. contg. phosphate and Rh ions in acid soln., e. g., that obtained by the reaction of a Rh compd. with  $\text{H}_2\text{PO}_4$  in a  $\text{H}_2\text{SO}_4$  soln. Ag articles may be coated with Rh in this way.

**Electrolytic separation of copper, gold and silver.** Chilesalpeter G. m. b. H. Ger. 577,892, June 6, 1933. Solns. of O-free I compds. of the metals and  $\text{NH}_4\text{I}$  are used.

**Alkali lye.** Akt.-Ges. für Zellstoff- und Papierfabrikation and Erich Bayer. Ger. 577,607, June 2, 1933. Foreign metals are removed from alkali lye by treatment with alkali amalgam. The lye may be electrolyzed for this purpose with Hg or amalgam as the cathode.

**Piperidine.** Robinson Brothers Ltd. and Deric W. Parkes. Brit. 395,741, July, 24, 1933. Piperidine sulfate is obtained by electrolytic reduction of pyridine in the cathode chamber of a diaphragm cell, the catholyte contg. 2.0–6.0 equivs.  $\text{H}_2\text{SO}_4$  of the pyridine present. The temp. is 70–85° for the lower limit of acidity and 20–50° for the higher. The anolyte consists of acid of such strength as to prevent loss of acid by the catholyte, since such loss may cause excessive production of dipiperidyls and formation of a gelatinous ppt., but not to dissolve the anodes. The anodes, cathodes and cell linings are of Pb. Piperidine is produced from the sulfate by treatment with  $\text{H}_2\text{SO}_4$  and distn. The crude piperidine is dried and allowed to stand over NaOH before final distn.

**Electric furnaces.** Paul L. J. Miquet and Marcel P. Perron. Fr. 750,108, Aug. 5, 1933. Construction of electrodes.

**High temperature electric furnace.** Gotthardwerke A.-G. für elektrochemische industrie and Arturo Paoloni. Swiss 161,514, July 17, 1933. An elec. furnace for temps. of 1400–1900° is described. The chambers are built of SiC.

**Electric furnace for manufacture of tungsten carbide.** Gorham W. Woods (to Hitches Tool Co.). U. S. 1,932,499, Oct. 31. A crucible is placed between upper and lower elec. conductive plates which may be formed of Cu and cooled by circulating water. The upper plate is provided with an opening to receive the material to be fused which is fed by gravity from a laterally curved tunnel above the opening. Various other structural details also are described.

**Electrolytic furnaces for the production of magnesium from molten magnesium chloride.** Société de Produits Chimiques des Terres Rares (to Johnson Matthey & Co. Ltd.). Brit. 396,820, Aug. 17, 1933, and 396,827, Aug. 17, 1933.

**Electrical induction furnaces.** Ludwig Dreyfus (to Almänna Svenska Elektriska Aktiebolaget). U. S. 1,935,046, 7, Nov. 14. Structural and elec. features.

**Electrical resistance furnace.** John T. Nichols (to American Sheet and Tin Plate Co.). U. S. 1,933,532, Oct. 31. Structural and mech. features.

**Cylindrical electric resistance furnace suitable for heating salts, etc.** Oskar Zingg (to Akt.-Ges. Brown, Boveri & Cie.). U. S. 1,932,567, Oct. 31. Structural features.

**Electric resistance heater furnace suitable for fusing zinc, etc.** Randolph Ganzler (to Akt.-Ges. Brown, Boveri & Cie.). U. S. 1,933,851, Nov. 7.

**Automatic temperature-regulating device for electric resistance furnaces.** Soc. anon. de Commentry, Fourchambault & Décazeville. Ger. 586,179, Oct. 17, 1933. Addn. to 576,208 (C. A. 27, 3675).

**Resistances.** The Globar Corp. Brit. 396,088, July 17, 1933. To increase the cond. of the terminal portions of a SiC resistor to facilitate making contact therewith these portions are impregnated with Si or a metal, e. g., Al, Ni, Fe, Co and (or) Cr. App. is described.

**Means for starting electrically heated salt-bath furnaces and like fusion furnaces.** Allgemeine Elektrizitäts Ges. (to Schmidt, inventor). Ger. 586,254, Oct. 19, 1933. Addn. to 411,278.

**Apparatus for discharge of materials from electric furnace shafts, etc.** George F. Weaton (to St. Joseph Lead Co.). U. S. 1,932,388, Oct. 31. Structural and mech. features.

**Electrodes.** Maschinenfabrik Oerlikon. Swiss 161,836, Aug. 1, 1933. Electrodes with a roughened surface especially useful for the decompn. of water are prepd. by coating the electrode with a metal which alloys with the electrode metal on heating. Thus, Ni or Fe electrodes are coated with Zn or Al by spraying, painting or dipping.

**Composite electrodes for metallurgical processes.** Vereinigte Aluminium-Werke A.-G. Ger. 577,733, June 3, 1933.

**Continuous rotary cathode apparatus for making metal strip.** Anton Kratky. Ger. 586,490, Oct. 21, 1933.

**Purifying mercury used as cathode in electrolysis.**

Knut W. Palmær. Brit. 396,041, July 18, 1933. In removing Fe, Ni and Co from solns. by electrolytic deposition into a Hg cathode the contaminated Hg is purified for re-use by treatment with an oxidizing agent, preferably one that may be readily re-oxidized, e. g.,  $\text{Fe}_2(\text{SO}_4)_3$ , a hypochlorite or  $\text{HNO}_3$ , which should be present in amt. less than equiv. to the metal impurity so that purification is not carried to completion in order to avoid attack on the Hg. The Hg may be continuously circulated between the cell and the purification app. so that the proportion of impurity is maintained at not above 0.5%. In 396,415, July 18, 1933, the Hg is purified by treatment with an agent indifferent to Hg, e. g., a mercurous salt, preferably in soln. A detailed example of the removal of Fe present in a soln. of an Al salt is given.

**Electrolytic electricity meter.** Wm. A. Childs. U. S. 1,931,954, Oct. 24. Various structural and operative details are described of an electrolytic meter which may have a liquid anode such as Hg.

**Fuse for interrupting alternating-current circuits.** Bertram Wellman and David C. Prince (to General Elec. Co.). U. S. 1,934,458, Nov. 7. A highly evacuated vessel contains a fuse link such as W supported between terminals composed of a metal such as Cu, Ag or Ni adapted to emit electrons at a relatively low temp. with a voltage drop of the order of 50 v. across the fuse terminals when the fuse is blown (the vessel being evacuated to a vacuum of the order of one-thousandth of a micron). U. S. 1,934,459 also relates to a generally similar device, the walls being thoroughly freed of occluded gas.

**Electrical contacts.** Samuel Ruben. U. S. 1,932,678, Oct. 31. A contact element such as that of a spot welding electrode has its base composed of a refractory metal of the sixth periodic group such as W and a highly conductive metal of the Cu-Ag class, and this base is provided with a contact-making surface of Be.

**Electrical shielding.** Henry J. Harris (to Bell Telephone Laboratories, Inc.). U. S. 1,933,261, Oct. 31. A shield suitable for use on telephone circuits, etc., consists of a plurality of adjacent layers of Fe and Cu including an outside layer of Cu.

**Purifying petroleum products by an electric field.** Charles W. Girvin (to Petroleum Rectifying Co. of Calif.). U. S. 1,931,725, Oct. 24. Material such as gasoline contg. acid or alkali is subjected to the action of an elec. field of greater voltage gradient toward the neg. electrode than toward the pos. electrode, the field being produced by a unidirectional current and the impurities in the material being moved to and collected on one of the electrodes and allowed to settle by gravity along the electrode. App. is described.

**Apparatus for electrothermic reduction of ores such as those of iron.** Sydney T. Wiles (to Buffalo Electric Furnace Corp.). U. S. 1,934,634, Nov. 7. Various structural, mech. and operative details are described.

**Bath for anodic treatment of aluminum.** Rudolf Auerbach (to General Elec. Co.). U. S. 1,933,301, Oct. 31. A bath which facilitates oxidation of Al surfaces contains  $\text{NH}_4$  phosphate 10 and  $\text{NH}_4$  vanadate 0.1%.

**Testing properties of materials by use of electric current from a thermionic tube circuit.** John J. Dowling (in

- part to Kenyon S. G. Somerville). U. S. 1,932,337, Oct. 24. Various elec. features are described.
- Elongated-flame production from electric arcs.** Engelbert Wist (to Presslicht-Patent-Verwertungsges. m. b. H.). U. S. 1,935,593, Nov. 14. In operations such as welding or for chem. processes, when employing an arc developed between concentric electrodes, a blast of a gas contg. hydrocarbon material is passed across the arc (the decomposition of the gas causing deposition of C on the electrodes). App. is described. Cf. C. A. 27, 1858.
- Cleaning gases.** Soc. anon. pour le traitement des minerais aluminopotassiques. Swiss 161,308, July 1, 1933. Coal dust and vapors are recovered from industrial gases by spraying the gases with a finely divided absorbent or adsorbent for the vapors and dust, and submitting the sprayed gases to an elec. pptg. process.
- Electrical precipitation of suspended particles from gases.** Richard Hensch (to International Precipitation Co.). U. S. 1,931,923, Nov. 11. Various details of app. and operation are described.
- Sterilizing liquids.** Lucien F. Grandchamp and Fernand H. L. Holweck. Fr. 750,031, Aug. 3, 1933. Liquids are sterilized by Ag ions produced by an elec. current using a Ag electrode.
- Electric rectifier.** Emil Duhme (to Westinghouse Elec. & Mfg. Co.). U. S. 1,932,067, Oct. 24. A portion of the surface of a piece of Cu is oxidized, a ductile metal layer such as Zn is placed in contact with the oxidized surface, the ductile metal is coated with an oxide compd. such as PbO<sub>2</sub> in a liquid carrier such as varnish lacquer and the coating is dried.
- Rectifier element of the cuprous oxide film type.** Stuart Ballantine (to Radio Corp. of America). U. S. 1,935,383, Nov. 14. A Cu plate is heated to an oxidizing temp. in air at a pressure of 2.5 cm. and for not more than 2 min. A film may be thus formed the thickness of which is so restricted that the rectification efficiency at 1000 kilocycles is not less than 75% of the efficiency at 60 cycles. App. is described.
- Mercury-arc rectifiers.** The British Thomson-Houston Co. Ltd. and John C. Read. Brit. 396,802, Aug. 14, 1933.
- Mercury-vapor rectifiers.** The General Electric Co. Ltd. and Enrico Gallizia. Brit. 395,747, July 20, 1933.
- Grid-regulated mercury-vapor rectifiers.** Akt.-Ges. Brown, Boveri & Cie. Brit. 395,779, July 27, 1933. Elec. features.
- Jet-wave mercury interrupter for use in rectifying electric currents.** Julius F. G. P. Hartmann. Brit. 395,748, July 20, 1933.
- Cut-out or electric short circuiting device.** Johannes A. M. van Liempt (to General Elec. Co.). U. S. 1,931,457, Nov. 7. A bronze of a refractory metal such as a W bronze is used for coating a W wire or the like.
- Discharge lamps.** Fidelity Films Ltd. and Frederick K. Crowther. Brit. 395,799, July 27, 1933. Addn. to 364,146 (C. A. 27, 2060). Means is described for insulating metal deposits forming on the insulation adjacent the cathode in a sound recording lamp.
- Discharge lamps.** Ted Eugene Foulke (to The British Thomson-Houston Co. Ltd.). Brit. 395,851, July 27, 1933.
- Discharge lamps.** Wm. J. L. Chinn. Brit. 396,582, Aug. 10, 1933.
- Discharge lamps.** N. V. Philips' Gloeilampenfabrieken. Brit. 397,074, Aug. 17, 1933.
- Discharge lamps.** Hans J. Spanner and Ulrich W. Doering (to The British Thomson-Houston Co. Ltd.). Brit. 397,162, Aug. 8, 1933.
- Discharge lamps for recording sounds.** Fidelity Films Ltd. and Frederick K. Crowther. Brit. 396,830, Aug. 17, 1933. Addn. to 364,146 (C. A. 27, 2060).
- Discharge lamps containing a vaporizable metal, e. g., sodium or mercury.** Albert E. Chapman. Brit. 395,711, July 17, 1933. Structural features.
- Discharge lamps wherein impurity is continually introduced to cause a ripple effect.** The General Electric Co. Ltd., Henry G. Jenkins and John W. Ryde. Brit. 395,738, July 24, 1933.
- Positive-column discharge lamps.** Daniel McF. Moore (to The British Thomson-Houston Co. Ltd.). Brit. 396,725, July 31, 1933.
- Discharge devices, e. g., lamps, rectifiers, having a liquid cathode and a directly or indirectly heated thermionic cathode.** Patent-Treuhand-Gesellschaft für elektrische Glühlampen m. b. H. (to The General Electric Co. Ltd.). Brit. 397,032, Aug. 17, 1933.
- Electrode positive-column lamp.** Charles H. Thomas (to Westinghouse Lamp Co.). U. S. 1,932,025, Oct. 24. A lamp with an inert gas filling has at least one hollow open ended electrode at least a part of the interior surface of which is provided with a thermionically active material of the Th group and which is exteriorly surfaced with elec. insulating material such as Th oxide.
- Arc lamp electrodes.** Compagnie Lorraine de charbons pour l'électricité. Brit. 395,580, July 20, 1933. To facilitate ignition of a lamp having a carbon with a mineralized core and a shell of substantially pure C the tip of the shell is slightly mineralized, e. g., by dropping a soln. of K<sub>2</sub>CO<sub>3</sub> or K borate onto it from a pipette, wrapping it in felt or blotting-paper impregnated with the soln. or dipping it into a bath.
- Electric lamp embodying a source of visible radiation combined with a source of ultra-violet radiation.** George Sperti (to Sperti Lamp Corp.). Brit. 396,210, Aug. 3, 1933.
- Daylight, etc., lamps.** Patent-Treuhand-Gesellschaft für elektrische Glühlampen m. b. H. (to The General Electric Co. Ltd.). Brit. 397,006, Aug. 17, 1933. One or more elec. discharge lamps having thermionic electrodes and filled with rare gas at a low mm. pressure are arranged around the middle of 1 or more elec. discharge lamps having thermionic electrodes and filled with rare gas and metal vapor assuming a pressure of above 50 mm. in operation.
- Flash-light lamps.** N. V. Philips' Gloeilampenfabrieken. Brit. 396,411, Aug. 2, 1933. See Ger. 578,097 (C. A. 27, 4182).
- Electric battery safety lamps.** Samuel A. Pollock. Brit. 396,089, July 20, 1933.
- Sealing lead-in wires into vitreous envelopes.** Siemens & Halske, A.-G. Brit. 396,103, July 31, 1933. A vacuum-tight seal for securing elec. current conductors into quartz or other refractory glass vessels is effected by using as conductors refractory metal strips of a max. thickness of about 20  $\mu$ . The strips may be of Ta, Nb, Mo, W, W-Mo alloys, etc., and the sealing is effected, as far as possible, in the absence of H, e. g., by a C-flame arc, an elec. furnace or by embedding a C core in the quartz body and circulating eddy currents therethrough. The metals are pretreated to expel occluded gases by heating *in vacuo*. Ta conductors are first anodically polarized in N H<sub>2</sub>SO<sub>4</sub> with a potential of about 90 v.

## 5 PHOTOGRAPHY

E. P. WIGHTMAN

**Antifogging agents in developers.** A. Steigmann. *Phot. Korr.* 69, 88 (1933). A review and discussion are given. E. P. Wightman

**Decorating cellulose ester material (U. S. pat. 1,933,810) 23.** Carboyanine dyes [having good photosensitizing properties] (U. S. pat. 1,934,657) 25.

**Color photography.** Michele Martinez (to A. H. Johnson & Co. (Paper) Ltd.). U. S. 1,935,477, Nov. 14. A surface such as celluloid is coated with at least one photosensitive layer contg. potential colors; the coated surface is exposed to the action of light, potential colors are then removed from those parts which have not been affected by light; the surface is then applied to a support

contg. at least one agent adapted to develop the colors required from the potential colors remaining on the surface. Various details and modifications are described.

**Color photographs.** Anton Jasmatzi. *Fr.* 749,922, Aug. 1, 1933. A proof having a basis of Ag obtained on Ag halides is toned toward the red by substituting the Ag of the proof by Ni dimethylglyoxime or its homologs.

**Photographic materials.** 1. G. Farbenind. A.-G. *Fr.* 41,770, Apr. 13, 1933. Addn. to 656,569 (*C. A.* 23, 4154). A colored layer which is not decolorized by development and is combined with a layer of a binder contg. Ag dispersed in colloidal form, is used as protection against halation in photographic materials.

**Photographic filter or antihalation layers.** 1. G. Farbenind. A.-G. *Brit.* 396,646, Aug. 10, 1933. A filter or antihalation layer consists of a colloid carrier in which is incorporated a dye obtained by condensing equimol. proportions of an aromatic or cyclic aldehyde and a cyclic compd. having a reactive  $\text{CH}_2$  group. Examples are given of layers formed by incorporating the condensation products of (1) malonyl urea and 4-dimethylaminobenzaldehyde-2-sulfonic acid (I) and (2) thiobarbituric acid and I in a layer of  $\text{NH}_4$  polyglucuronate, and the condensation products of (1) Na-*p*-benzaldehydesulfonic acid and 3-oxythionaphthene (II), (2) *m*-oxybenzaldehyde and II, (3) Na-benzaldehyde-2,4-disulfonate and II and (4) Na-*p*-benzaldehydesulfonate and 3-oxy-selenonaphthene in layers of gelatin. *Cf. C. A.* 27, 3156.

**Sensitized photographic paper.** Paul C. Seel (to Eastman Kodak Co.). U. S. 1,933,821, Nov. 7. A paper support is provided on both sides with a waterproofing coating contg. a polymerized vinyl compd. such as polymerized vinyl acetate and a coating contg. light-sensitive salts is placed over the waterproofing coating on one side.

**Light-sensitive layer.** Maximilian P. Schmidt and Hermann Neuroth (to Kalle & Co. A.-G.). U. S. 1,934,011, Nov. 7. As light sensitive substances, there are used aromatic diazo compds. such as the  $\text{CdCl}_2$  double salt of 4-diethylamino-2-hydroxy-1-diazo-benzene, capable of coupling, in mixt. with a diazo sulfonate such as

1 the Na salt of naphthalene- $\beta$ -diazo-*N*-sulfonic acid, incapable of coupling. Layers are thus prepd. which are stable and yield a neg. copy from a pos. pattern when exposed under the pattern. *Cf. C. A.* 27, 239.

**Light-sensitive layers.** Philippe Frangiali and Robert Lantz. *Fr.* 750,080, Aug. 3, 1933. An aromatic sulfonic acid or a sol. salt thereof is added to the aq. soln. contg. a diazo compd. and an azo coupling component to maintain the mixt. in soln.

2 **Photosensitive layer sensitive to ultra-violet.** Samuel E. Sheppard and Leon W. Kberlin (to Eastman Kodak Co.). U. S. 1,934,451, Nov. 7. Layers such as those applied to paper comprise dextrose and an O-contg. compd. of a metal of the 6th periodic group having an at. wt. between 90 and 200, such as Na tungstate or molybdate.

**Desensitizing halogen silver films.** Eugen Riesz. *Ger.* 577,666, June 2, 1933. Ag halide films are desensitized by treatment with pyrazinium compds. or derivs. and reagents forming quaternary cyclammonium salts. Derivs. contg. condensible  $\text{CH}_3$  or  $\text{CH}_2$  groups are treated with aromatic aldehydes. Thus, an exposed plate is treated with an equiv. mixt. of 2,5-dimethylpyrazine and  $\text{Me}_2\text{SO}$ . Similarly, the plate may be treated with an aq. soln. of 1,5-dimethyl-2-[(benzylidene)methyl]-pyrazinium nitrate obtained from an equiv. mixt. of 2,5-dimethylpyrazine-methyl nitrate and  $\text{BzH}$ .

**Photographic developer.** John I. Crabtree and John F. Ross (to Eastman Kodak Co.). U. S. 1,933,789, Nov. 7. A developer including formalin, an alkali and *p*-aminophenol sulfate is free from fogging effects when used at high temps. *Cf. C. A.* 27, 5266.

5 **Regenerating used photographic developers.** Kenneth C. D. Hickman and Walter J. Weyerts (to Eastman Kodak Co.). U. S. 1,933,804, Nov. 7. For regenerating a used developer and sepg. sol. bromides from it, there is added a soln. of a sol. Ag salt such as  $\text{AgNO}_3$  and a water-sol. Al salt such as K Al sulfate. Salts of Cr, Co, Cu, Ni, Bi, Pb, Ba, Mn, Mg or Zn also may be used. *Cf. C. A.* 28, 58.

**Carbon-arc lamps for photographic, etc., purposes.** Benjamin J. Hall. *Brit.* 396,876, Aug. 17, 1933.

## 6- INORGANIC CHEMISTRY

A. R. MIDDLETON

**Germanium. XLI.** Some new salts of fluogermanic acid. L. M. Dennis, B. J. Staneslow and W. D. Fox-geng. *J. Am. Chem. Soc.* 55, 4392 6(1933); *cf. C. A.* 24, 5247. Salts were prepd. from  $\text{H}_2\text{GeF}_6$  and the following bases (figures in parentheses are d $_{25}^\circ$ ):  $\text{NH}_3$  (2.564);  $\text{NH}_4\text{OH}$  (2.492) (forms dihydrate (2.229)), hydrazine (2.406); aniline (1.579); monomethylaniline (1.631), dimethylaniline (1.548). All are sol. in  $\text{H}_2\text{O}$ , with some hydrolysis. T. H. Chilton

**Recovery of iodine from metallic iodides by oxidation with technical nitric acid.** Rush F. McCleary and Fd. F. Degering. *Ind. Eng. Chem., Anal. Ed.* 5, 420(1933). — An app. is shown which is suitable for the recovery of  $\text{I}_2$  from  $\text{ZnI}_2$  residues obtained in the presence of  $\text{ZnEt}_2$ . Conc'd.  $\text{HNO}_3$  in small portions is added to the cake in slight excess over the calcd. quantity. The  $\text{I}_2$  collects on the sides of the reaction vessel but is easily expelled by heating into a larger chamber where it comes in contact with a surface cooled by running water. W. T. H.

**The liberation of iodine from alkali iodides by means of oxygen of the air through the intervention of nitrous gases.** Rasik L. Datta. *J. Soc. Chem. Ind.* 52, 350T(1933). — A hot mixt. of 1 mole alkali iodide in 0.75 mole conc'd.  $\text{H}_2\text{SO}_4$  is treated with air contg. oxides of N, resulting in quant. oxidation of the iodide. The N oxide catalyst is completely recovered by absorption in  $\text{H}_2\text{SO}_4$ , from which it is liberated by addn. of alkali iodide. H. A. B.

**Hydrides of boron II.** The preparation of  $\text{B}_2\text{H}_6$ : its thermal decomposition and reaction with hydrogen. Anton B. Burg and H. I. Schlesinger. *J. Am. Chem. Soc.* 55, 4009 20(1933); *cf. C. A.* 26, 663.— $\text{B}_2\text{H}_6$  is

prepd. by a flow method of heating  $\text{B}_2\text{H}_6$ . Its m. p. is  $-123.3^\circ$  and its vapor tension 53 mm. at  $0^\circ$ . Heating  $\text{B}_2\text{H}_6$  for a short time yields  $\text{H}_2$ ,  $\text{B}_2\text{H}_4$ ,  $\text{B}_4\text{H}_{10}$ , probably  $\text{B}_2\text{H}_8$ , and non-volatile solids. Long heating yields also  $\text{B}_2\text{H}_4$  and  $\text{B}_{10}\text{H}_{14}$ . Short heating of  $\text{B}_2\text{H}_6$  with a large quantity of hydrogen gives only  $\text{B}_2\text{H}_4$  and  $\text{B}_4\text{H}_{10}$ . Heating  $\text{B}_4\text{H}_{10}$  with  $\text{H}_2$  yields  $\text{B}_2\text{H}_4$  and  $\text{B}_4\text{H}_{10}$ .  $\text{B}_2\text{H}_4$ ,  $\text{B}_4\text{H}_{10}$ , and  $\text{H}_2$  thus form a system of reversible reactions. Long heating of this mixture with  $\text{HCl}$  as a catalyst gives 33% yields of  $\text{B}_4\text{H}_{10}$ . III. Dimethoxyborane. Anton B. Burg and H. I. Schlesinger. *Ibid.* 55, 4020-5(1933). — Reaction of  $\text{B}_2\text{H}_6$  with  $\text{MeOH}$  yields  $(\text{MeO})_2\text{BH}$ ; m. p.  $-130.6^\circ$ ; b. p.  $25.9^\circ$ .  $(\text{MeOBH})_2$ , a white solid which decomposes to yield  $\text{B}_2\text{H}_4$ ,  $(\text{MeO})_2\text{B}$ , and  $(\text{MeO})_2\text{BH}$ , also is formed.  $(\text{MeO})_2\text{BH}$  is entirely unassociated in the vapor state. It hydrolyzes to yield  $\text{H}_2\text{B}(\text{OH})_2$  and  $\text{MeOH}$ . It decomposes reversibly, yielding  $\text{B}_2\text{H}_4$  and  $(\text{MeO})_2\text{B}$ . A. B. Burg

**Chemical and crystallographic investigations on nickel-nitrites of bivalent metals.** A. Ferrari and R. Curti. *Gazz. chim. ital.* 63, 499-506(1933). — In establishing the existence of the complex  $\text{Ni}(\text{NO}_2)_6^{4-}$  ion (*cf. C. A.* 24, 5559; 26, 4221; Mouseron and Cariteau, *C. A.* 27, 1839), discordant results were obtained by the 2 groups of investigators. F. and C. present further data on the prepn. and properties of 3 nickel-nitrites and the impossibility of prepg. certain others. When heated at  $100^\circ$ ,  $\text{Ba}_2[\text{Ni}(\text{NO}_2)_6]$  (*cf. Pogg. Ann.* 118, 296(1863); M. and C., *loc. cit.*) loses 3.75 mols. of  $\text{H}_2\text{O}$  per  $\text{Ni}(\text{NO}_2)_6$ , without changing its lattice structure, so that the loss is probably  $\text{H}_2\text{O}$  of a zeolitic nature.  $\text{Sr}_2[\text{Ni}(\text{NO}_2)_6]$  (*cf.*

is oxidized to  $\text{Sn}^{++++}$  prior to pptn. with  $\text{H}_2\text{S}$ , colorless  $(\text{NH}_4)_2\text{S}$  can be used in the subsequent treatment.

W. T. H.

**Assaying of non-metallic minerals.** E. S. Sinegub. *Mineral. Suir'e* 8, No. 7, 2-14(1933).—The proposed methods for sampling and assaying of non-metallic ores are mostly based on the foreign practice. C. B.

**Determination of antimony.** R. I. Shreider. *Khim. Farm. Prom.* 1933, 151-2.—Heat 2-300 mg. of substance in a Kjeldahl flask with 2 g. of  $\text{K}_2\text{SO}_4$  and 3 cc. of concd.  $\text{H}_2\text{SO}_4$ . After 30 min., cool, carefully add 25 cc. of water, boil off  $\text{SO}_2$ , add 4 cc. of  $\text{HCl}$  soln. and det. the Sb content by the bromate method. L. Nasarevich

**Mold growth tests for minute amounts of arsenic.** H. R. Smith and E. J. Cameron. *Ind. Eng. Chem., Anal. Ed.* 5, 400-1(1933). The garlic odor caused by the action of molds may be used for the detection of traces of As; 0.001 mg. of As will suffice to give the test. Full directions are given. W. T. H.

**Reading the Gutzeit arsenic test on a graph.** Claude E. Hynds. *N. Y. State Dept. Agr. & Markets, Ann. Rept.* 1931, 96-7(1932).—By means of a plotted graph from known values of As and length of the stain on the paper strip, unknown stains may be read with greater accuracy. C. R. Fellers

**New color test for bismuth.** A. D. Powell. *Quart. J. Pharm. Pharmacol.* 6, 464-6(1933).—To 10 ml. of the aq. soln. to be tested add 2 ml. dil.  $\text{HCl}$  and about 0.5 g.  $\text{KI}$ . Mix and add 5 ml. alc. or acetone and 5-10 ml.  $\text{EtOAc}$ . Shake and allow to sep. A red color in the upper layer indicates Bi. W. O. J.

**Detection of cesium, rubidium and thallium.** P. Robin. *J. pharm. chim.* 18, 381-7(1933).—Ppt. K, Cs, Rb and Tl from a 10-20% soln. free from  $\text{NH}_4$  as  $\text{NaX}_2[\text{Co}(\text{NO})_2]$ . Calcine the ppt. at a low temp. in a metal capsule, dissolve out the nitrites and convert these into chlorides by evapn. with excess of  $\text{HCl}$ . Eliminate most of the  $\text{KCl}$  and  $\text{NaCl}$  by means of a mixt. of  $\text{HCl}$  22 Bc — 35.21% 1 vol., and 96% alc. 2 vols., then ppt. Cs, Rb and Tl (=X) as  $\text{Ag}_2\text{X}[\text{Bi}(\text{NO}_3)_3]$  (cf. Ball and Abram, C. A. 8, 1247, 1248), allow to stand for 24 hrs., put the ppt. on a glass filter, wash with a few drops of alc., hydrolyze on the filter with dil.  $\text{HNO}_3$ , evap. the nitrates, take up with  $\text{H}_2\text{O}$  and look for Cs, Rb and Tl in the spectroscope. Cs and Rb were found by this method in 8 French mineral waters; Tl was absent. S. Waldhott

**Electrolytic determination of chromium with the rotating mercury electrode.** Panta S. Tutundzhic. *Z. anorg. allgem. Chem.* 215, 19-22(1933).—Fresh Hg should be used for each analysis, about 25 g. when 0.1 g. of Cr is present and 40-45 g. for 0.2 g. Cr. For violet solns. it is best to make the soln. contain 0.1 cc. of concd.  $\text{H}_2\text{SO}_4$  to 25-100 cc. of electrolyte, and twice as much acid should be added if the  $\text{Cr}_2(\text{SO}_4)_3$  soln. is green. At the start, use a current of 0.5 amp. at 8 v. between the electrodes. After 10 min. increase the current to 1.5 amp. when the p.d. will rise to 14-16 v. During the electrolysis, the temp. of the soln. will rise to nearly 90°. W. T. H.

**Increasing the sensitivity of a microchemical test for cobalt and copper and the induced test for ferrous iron, ferric iron and nickel.** I. M. Korenman. *Z. anal. chem.* 95, 44-8(1933).—A soln. of  $(\text{NH}_4)_2[\text{Hg}(\text{CNS})_4]$ , prepd. by dissolving 5 g. of  $\text{HgCl}_2$  and 5 g. of  $\text{NH}_4\text{CNS}$  in 5 cc. of water, has been recommended as a sensitive reagent for  $\text{Co}^{++}$  and  $\text{Cu}^{++}$ ; a blue ppt. is obtained with the former and a green ppt. with the latter. A white amorphous ppt. of similar constitution is obtained with  $\text{Zn}^{++}$ . If there is a little  $\text{Zn}^{++}$  present, so that mixed crystals are formed, the sensitivity of the test for  $\text{Co}^{++}$  or  $\text{Cu}^{++}$  is increased greatly. Thus if a drop of the soln. to be tested is mixed with a drop of the reagent together with a tiny drop of 0.25%  $\text{ZnSO}_4$  soln., as little as 0.02  $\gamma$  of Co can be detected at a diln. of 1:100,000. Moreover, in the absence of Zn, tests for Fe and Ni are not obtained in dil. solns. but after a little  $\text{Zn}^{++}$  has been added, as little as 0.002 mg. of  $\text{Fe}^{+++}$ , 0.012 mg. of  $\text{Fe}^{++}$  or 0.033

mg.  $\text{Co}^{++}$  can be detected in 1 cc. of soln. at dilus., resp., of 1:500,000, 1:85,000 and 1:30,000. W. T. H.

**Use of amyl alcohol in the sodium diethyldithiocarbamate method for estimation of copper.** R. W. Thatcher. *J. Am. Chem. Soc.* 55, 4524(1933).—For detg. Cu in org. tissues by the McFarlane method (C. A. 27, 46) isoamyl alc. is better than amyl alc. W. T. H.

**Colorimetric determination of iron with sulfosalicylic acid.** F. Alten, W. Weiland and E. Hille. *Z. anorg. allgem. Chem.* 215, 81-91(1933).—Detailed directions are given for detg. the Fe content of drinking water (cf. Lapin and Kill, C. A. 26, 790).  $\text{Fe}^{+++}$  in acid solns. gives a red color with sulfosalicylic acid. The color is similar to that obtained in the KCNS test for  $\text{Fe}^{+++}$ , and the reaction is about equally sensitive. In alk. soln. the reagent gives a yellow color with both  $\text{Fe}^{++}$  and  $\text{Fe}^{+++}$ . It is possible, therefore, to det. the total Fe in alk. soln. and the  $\text{Fe}^{+++}$  in acid soln. by measuring the actual depth of color, with the aid of a suitable light filter, or comparing with standards. Contrary to previous statements, the depth of color produced with  $\text{Fe}^{+++}$  in acid solns. appears to be somewhat intensified by the presence of  $\text{Fe}^{++}$ , but allowance for this effect can be made. To det.  $\text{Fe}^{+++}$ , take a little of the soln. contg. not over 2 mg. of Fe, dil. to about 20 cc., add 10 cc. of  $\text{N NH}_4\text{Cl}$  and 1 cc. of indicator (cold satd. soln. of a dinitrophenol). If the soln. is already alk. to the indicator, add 0.1 N  $\text{HCl}$  until the yellow color disappears. Carefully add 0.1 N  $\text{NaOH}$  until a permanent yellow is obtained, add 5 cc. of sulfosalicylic acid reagent (10 g. of solid dissolved in 20 cc. of water and treated with  $\text{NaOH}$  until the  $\text{pH}$  is 2 and then dild. to 100 cc.) and 5 cc. of citrate buffer soln. (Dissolve 21 g. of citric acid in 200 cc. of  $\text{N NaOH}$ , dil. with water to 1 l. Treat 3 cc. of this citrate soln. with 7 cc. 0.1 N  $\text{HCl}$ .) After 3-4 hrs. measure the color. To det. the total Fe, take a similar quantity of soln., add 10 cc. of  $\text{N HCl}$ , 2 cc. of reagent (20 g. of sulfosalicylic acid in 100 of water) and 20 cc. of the above citrate soln. which has not been mixed with  $\text{HCl}$ . Add  $\text{NaOH}$  to change the red soln. to yellow, and after the soln. is a distinct yellow add 10 of  $\text{N NaOH}$  and 20 cc. of borate buffer soln. (Dissolve 12 g. of  $\text{H}_3\text{PO}_4$  in 100 cc. of  $\text{N NaOH}$  and dil. to 1 l. Mix 46 cc. of this soln. with 54 cc. of  $\text{N NaOH}$ .) Measure the color after 3-4 hrs. W. T. H.

**A quantitative study of the lanthanum-neodymium separation.** P. W. Selwood. *J. Am. Chem. Soc.* 55, 12, 4900-1(1933).—Tests with 8 procedures show that Prandtl's basic ammonia sepn. is the best, but in actual practice it is often found that a reversal of the solv. order facilitates rapid purification. W. T. H.

**Colorimetric determination of magnesium.** F. Alten, H. Weiland and B. Kirmies. *Angew. Chem.* 46, 697-8(1933); cf. C. A. 28, 66.—The soln. contg. 10-500  $\gamma$  Mg is evapd. to about 1 cc. and weakly acidified with  $\text{AcOH}$ . Na acetate is added and Fe, Al, Mn, Cu, Zn and Ti are pptd. with hydroxyquinoline. The alk. earths are pptd. without previous filtration, by addn. of  $\text{NH}_4$  oxalate.  $\text{NaOH}$  and Na tartrate are added to the filtrate to keep any Al which is still present in soln. and Mg is pptd. as hydroxyquinolate. This ppt. is colored by coupling it to diazobenzenesulfonic acid and compared with standard Mg solns. The prepn. of reagents and the procedure are given in detail. Exptl. results show very good agreement. Four references. K. K.

**Determination of molybdenum in manganese minerals.** H. Hauptmann and M. Balconi. *Z. anorg. allgem. Chem.* 214, 380-4(1933).—Tests were made on the detn. of Mo by measuring the red color produced with KCNS and  $\text{SnCl}_2$  and the red color produced by the action of a soln. of phenylhydrazine in dil.  $\text{H}_2\text{SO}_4$ . The first color develops best in a soln. contg. 4% of free acid. The test is very sensitive and serves to detect as little as 0.005 mg. in 20 cc. but the color is not very stable. The latter test is only about  $1/4$  as delicate, but the color developed is less sensitive with respect to temp. changes.

Directions are given for applying both tests to the analysis of minerals that are decomposable in HCl. W. T. H.

**Several microchemical tests for the identification of molybdenum and tungsten.** G. Tartarum. *Ann. chim. applicata* 23, 367-72 (1933). The reaction products of pyrocatechol with molybdic and tungstic acids have sexivalent Mo and W atoms, rather than quinquevalent, as indicated by Martini. *C. A.* 26, 5870. Thus the compn. is  $[O_2Mo(C_6H_4O_2)_2] \cdot [H_2(C_6H_4NH_2)_2 \cdot 3H_2O]$ , with a similar W compd. A. W. Contieri.

**Favorable conditions for the precipitation of zinc sulfide and hydrated alumina and a method for the gravimetric separation of zinc and aluminum.** J. N. Fiers. *Z. anal. Chem.* 95, 136 (1933). The methods for sep. Zn from Al are discussed, and it is shown that it is reasonable to assume that it is better to ppt. ZnS first rather than to attempt to ppt.  $Al(OH)_3$  in the presence of  $Zn^{++}$ . The conditions for pptg. ZnS were studied and the results of considerable exptl. work compared with those obtained by previous investigators. W. T. H.

**Determinations of small quantities of fluorine. I. Steiger-Merwin reaction—optimum conditions and interference.** H. J. Wichmann and Dan Dahle. *J. Assoc. Official Agr. Chem.* 16, 612-19 (1933).—In the colorimetric detn. of F by means of its bleaching action on "peroxidized" Ti (Steiger, *C. A.* 2, 1104; Merwin, *C. A.* 3, 2919; Sharpless, *C. A.* 27, 4562), the bleaching action increases with increasing  $pH$  to an optimum of approx. 1.5 and then rapidly decreases to practically 0 at  $pH$  of about 2.5. The concn. of both Ti and F has a strong influence on both the sensitivity and practical range of the reaction at the optimum  $pH$ : (1) the bleaching per unit F increases as the concns. of F increase and the concns. of Ti decrease; (2) up to certain limits it is proportional to the quantity of F present; (3) above this limit the bleaching per unit of F decreases. Numerous curves are given and discussed, the curves showing the interference with the detn. of  $PO_4$ , phosphates, Al,  $K_2SO_4$ , NaCl and "apple wash" (org. matter derived from apple skins by the usual rapid methods of spray-residue analysis). Some of these interferences suggest the formation of unknown complexes that prevent the accurate detn. of F because the effect of the foreign substance and F on the Ti is not additive. II. **Steiger-Merwin reaction—details of procedure.** *Ibid.* 619-24. A technic for the colorimetric detn. of small quantities of F (down to 0.002 mg.) based on the above findings is described. F can be successfully isolated from fruits and vegetables without ashing by a double Willard and Winter distn. (*C. A.* 27, 681) on (1) a subsample of the org. matter, and (2) on the oxidized first distillate after evapn. The crucial points of the method consist in carrying out the detn. at a controlled  $pH$  of 1.50  $\pm$  0.02 and of using an amt. of Ti in accordance with the expected quantity of F and the ability of the operator to match colors, and obtaining the F content from a previously detd. curve prepd. with the amt. of Ti used. W. and D. prefer the use of a photometer, as being more accurate, but in view of its much higher cost as compared with Nessler tubes, the method has been worked out so as to permit the use of either. Typical results obtained by this method on various foods are tabulated. A. P.-C.

**Titration of ammonia in the presence of boric acid.** Edward W. Meeker and E. C. Wagner. *Ind. Eng. Chem., Anal. Ed.* 5, 396-8 (1933).—For collecting the  $NH_3$  distd. during the Kjeldahl analysis it has been recommended to use a soln. of  $H_3BO_3$  instead of an excess of  $H_2SO_4$  but some difficulty has accrued with respect to the indicator. Procedures are given here which serve for the macro- and micro-detn. of N. Methyl red is recommended and the color is matched with a control of the same  $H_3BO_3$  content. W. T. H.

**Colorimetric method for the determination of carbon dioxide in gas mixtures.** Perry W. Wilson. *Science* 78, 461-2 (1933); cf. Wilson, Orcutt and Peterson, *C. A.* 26, 5872. In view of some criticisms concerning the method, further information is given concerning the

choice of indicators, the comparisons with the Hellige color disks and the prepn. of a plot to assist in computing the results. For detns. in the acid range above 0.15%  $CO_2$ , bromothymol blue gives good results but in the alk. range cresol red or  $\alpha$ -naphtholphthalein should be used. W. T. H.

**Direct titration of sulfate. Tetrahydroxyquinone as an internal indicator.** W. C. Schroeder. *Ind. Eng. Chem., Anal. Ed.* 5, 403-6 (1933).—To 25 cc. of soln. contg. 2-20 mg. of  $SO_4^{--}$  add 0.030 N (or weaker) HCl until the soln. is just acid to phenolphthalein. The soln. must be below 30° in temp. Add 25 cc. of EtOH and 0.20-0.22 g. of a mixt. prepd. by triturating a little tetrahydroxyquinone with considerable KCl. The soln. will have a yellow color. Titrate with 0.025 N  $BaCl_2$  until a brown color indicates the approach to the end point. Then add the  $BaCl_2$  reagent in portions of 2-3 drops until the whole soln. assumes a red color. One hundred and twenty references. W. T. H.

**Determination of cyanides and thiocyanates by the mercurimetric method.** Al. Ionesco-Matin and Minc. A. Popesco. *Chimie & Industrie Special No.*, 1011-13 (June, 1933); cf. *C. A.* 21, 2445, 3575. The method is applicable to the detn. of cyanides and thiocyanates, either alone or in presence of each other, with the same degree of accuracy as present standard methods. A. Papineau-Couture.

**Microchemical analyses for slag inclusions in steel.** R. Trege and H. Albr. *Jernkontorets Ann.* 116, 457-71 (1933). As a result of the study of standard methods for detg.  $SiO_2$ ,  $Al_2O_3$ , FeO, MnO and MnS in steel, numerous necessary conditions were detd. Twenty-one references. H. C. Duus.

**Distillation of hydrocyanic acid from sulfuric acid solutions.** Samuel Morris and Vireil G. Lilly. *Ind. Eng. Chem., Anal. Ed.* 5, 407-8 (1933).—In dist. HCN from  $H_2SO_4$  solns., no retardation was caused by the presence of Cl. Loss of HCN occurs unless the rubber stoppers are protected with Sn foil. Ferrocyanide is a common impurity in com. "C. P." cyanides and when they are present high results are obtained. With ferrocyanide-free cyanides, the method of Pagel and Carlson (*C. A.* 27, 243) is accurate. The rate of hydrolysis of HCN is a function of the acid concn. Thirteen references. W. T. H.

**Flask oxidation in the determination of sulfurous acid by distillation.** P. F. Nichols and H. M. Reed. *Ind. Eng. Chem., Anal. Ed.* 5, 398-9 (1933).—In detg.  $SO_2$  in dried fruits or similar products, some  $SO$  may be oxidized in the flask and other gases may be evolved which will have a reducing action similar to that of  $SO_2$ . Expts. with synthetic solns. of  $SO_2$  show that none of the expedients hitherto suggested is capable of preventing entirely some oxidation in the flask. Gravimetric detn. by the Monier-Williams method gave the highest yields, but the preliminary heating can be omitted without serious loss of accuracy. W. T. H.

**Inhibiting effect of certain substances upon the oxidation of sulfurous acid.** J. S. Mitchell, G. A. Pitman and P. F. Nichols. *Ind. Eng. Chem., Anal. Ed.* 5, 415-16 (1933). Expts. with  $SO_2$  solns. showed that the presence of sucrose, mannitol, lactose, glycerol, etc., tends to prevent the oxidation of  $SO_2$ , but the addn. of such substances as inhibitors during the detn. of  $SO_2$  in dried fruits did not serve to increase the  $SO_2$  found. W. T. H.

**Determination of sulfuric anhydride in sulfonated oil and other products.** Ralph Hart. *Ind. Eng. Chem., Anal. Ed.* 5, 413-14 (1933); cf. *C. A.* 26, 5871. The method described depends upon the fact that the "organically combined" sulfate after conversion into its "monosodium compds." is sol. in ether and may be extd. from satd. aq. solns. of NaCl or  $Na_2SO_4$ . Then, if the ether is distd. off and the residue weighed after ignition, it will consist of  $Na_2SO_4$  equiv. to just  $1/2$  the original sulfate content;  $2R \cdot SO_3Na = Na_2SO_4 + SO_3$ , etc.;  $2R \cdot SO_3Na = Na_2SO_4 + SO_2$ , etc. W. T. H.

**Report on (the analysis of) plants.** O. B. Winter.

*J. Assoc. Official Agr. Chem.* **16**, 462-3 (1933), cf *C. I.* **27**, 244. Progress report. A. Papineau-Couture.

**Report on the preparation of plant material for analysis.** H. R. Kraybill. *J. Assoc. Official Agr. Chem.* **16**, 461-5 (1933), cf *C. I.* **27**, 244. The samples of cabbage leaves, apple fruits, carrots, apple shoots and tomato plants used for the previously reported studies were analyzed again at the end of 11 months. In most cases there was a slightly smaller quantity of free reducing substances and slightly larger quantity of sucrose, but the differences were not greater than the usual errors of the methods used. A. Papineau-Couture.

**Report on less common metals in plants. Spectroscopic method for determination of boron in plant material.** J. S. McHargue. *J. Assoc. Official Agr. Chem.* **16**, 465-71 (1933). The technique of a method worked out by McHargue and R. K. Cullen (*C. I.* **26**, 869) is described. It consists essentially in saturating the plant material with 10% B free  $K_2CO_3$  ashing, making distinctly red with satd. citric acid soln., adding  $MgO$ , distilling in a special app. into 0.1 cc. 0.5%  $KOH$  and 10 cc.  $HClO_4$ , evaporating to dryness, taking up in a definite vol. of 5%  $HClO_4$  in  $MgO$ , observing the spectrum of the flame of  $MgO$  vapors produced in a special burner, and determining the no. of cc. of 0.01%  $KMnO_4$  which must be added to 0.1 cc. of  $HClO_4$  in a cell interposed between the flame and the spectrocope in order just to eliminate the brightest green band of the B spectrum. The corresponding amt. of B is obtained from a table or curve which should be prepared by the operator from known quantities of B because the sensitivity and adjustment of different spectroscopes vary widely. Only 1 hr. reagent must be used. From 0.1 to 0.001 p.p.m. B can be determined with an accuracy of 1 p.p.m. Pyroforming in  $O_2$  under controlled conditions by means of a specially designed burner which is used in detail the sensitivity can be increased to 100 p.p.m. The method is also applicable to analysis of mineral matter in natural water by making a survey modification in technique to burn the B into a stable form for analysis in  $MgO$ . A. P. C.

**Determination of halogens in organic substances.** J. E. Egan. *Knowl. from Ind.* **1933** 14, 8. The procedure is as follows: 100 cc. flask connected with 1 mm. vertical  $NaOH$  line. Cover the flask with 10 cc.  $HClO_4$  it to boil and pass the air through 100 cc.  $HClO_4$ . Det. the halo- content of the distillate by the method of L. Senius. I. N.

**Determination of nitrogen in organic compounds.** D. J. A. Kinn. *Farm. J.* **1933** 218-20. The method of Andersen and Jensen (*C. I.* **25**, 1400) is slightly modified for small quantities of material. I. N. Uchich.

**New method for the differentiation and determination of formaldehyde and acetaldehyde.** M. Ureca. *V. J. J. Soc. Hort. Shisunshi. Bull. su chin.* **53**, 900-18.

Both aldehydes give white ppts. with dimethyl- $\alpha$ -naphthol, but the speed of the reaction varies. By measuring the time required to give a visible ppt. it is possible to differentiate between the aldehydes and also to det., within 2%, the concn. of aldehyde in a mixt. As little as 1.5 mg. of  $HCHO$  is detected in 100 cc. of soln. and 50-100 mg. of  $CH_3CHO$  in a mixt., it is recommended to det. the content of aldehyde by the iodometric method. Then dil. the soln. to make it 1% and the time required to obtain a ppt. after treatment with resorcinol deriv. From an empirical table, the concn. of each aldehyde can be estd. W. I. H.

**Determination of chloroform.** M. Shchigol. *Khim. Zvezd.* **1933**, 150-1. Weigh out 10 drops of  $CHCl_3$  in a stoppered flask with 5 cc. of toluene. Shake 1-2 hrs. with 0.5%  $NaOH$ , cool, dil. with 10 cc. of  $HNO_3$  and det.  $Cl$  by the method of I. Nasruch.

**Fluorescence analysis.** F. H. Stock. *Sudden. Upoth.* **73**, 46 (1933). The importance of testing the various chemicals and materials in ultra-violet light for fluorescence (luminescence) phenomena is emphasized,

in connection with a description and illustration of the app. "Callophane," recently developed by the physicist Callo of Berlin especially for such work.

W. O. P.

**New method for determining aldehydes by quantitative Cannizzarization.** L. Palfiay, S. Sabatay and Denise Sontag. *Chimie & Industrie Special No.*, 1037-8 (June, 1933). Cannizzaro's reaction consists essentially in an oxido-reduction phenomenon, 1 mol. of aldehyde being oxidized to acid and the other reduced to an alc. radical, resulting in the formation of an ester which is saponated to give the free acid and alc. The reaction applies to aldehydes in which the  $CHO$  group is combined to an electronegative radical. In strongly alk. soln. the yields of alc. and acid are high, but not quant. By using 0.5%  $KOH$  in  $PhCHOH$  the reaction is quant. and can be used as an analytical method, except for aliphatic aldehydes for which it is only partial. A new acid glass should be used, Pyrex or Silbor should not be used, Boheman glass is suitable after treating for about 15 hrs. with 0.5%  $KOH$  in  $PhCHOH$ . The method also permits of easily preparing no. of esters and acids which can be obtained only with difficulty by other methods. A. P. C.

**Shaffer and Hartmann combined carbonate citrate method for determination of glucose.** J. O. Halveron and I. W. Sherwood. *Int. Eng. Chem., Anal. E.* **5**, 118 (1933), cf *C. I.* **15**, 1327-8. In some experiments the Cu-glucose ratio averaged 2.5 mg. more than the initial unit. In other words there was somewhat more reduction from a given wt. of glucose than that reported by Hartmann. The method is excellent but each chemist should carefully standardize his technique and should himself derive an expression for the ratio between the wt. of dextrose present and the wt. of Cu reduced. W. I. H.

**Detection and determination of fructose in presence of glucose.** Felix Fischl. *Chimie & Industrie Special No.*, 1125 (June, 1933), cf *C. I.* **27**, 3120. The optimum conditions for applying Ohlert's method (*C. I.* **26**, 865) to the detn. of fructose are: 10 cc. of soln. cont. less than 0.5% sugar in a wide mouthed flask add 50 cc.  $Cu$  soln.,  $CuSO_4$  50,  $HClO_4$  50,  $Na_2CO_3$  10,  $NaK$  tartrate 500,  $NaHPO_4$  1200, 1200-50% per l., place in the water bath at 60° for 5 min. with gentle turning, cool rapidly, dissolve the pptd.  $Cu$  directly in the soln. by addition of  $HCl$  and titrate with  $N/77.1$   $I_2$  of which 5 mg. fructose. A. Papineau-Couture.

**Argentometric evaluation of hexamethylenetetramine.** Gyula Miks. *Pharm. Zentralblatt* **74**, 642 (1933). Several methods are briefly reviewed and a new procedure is suggested. Five cc. of a 2% soln. of the sample is mixed with 45 cc. of 0.1%  $AgNO_3$  (excess) by vigorous shaking, the soln. is filtered and an aliquot part of the filtrate is acidified with 5 cc.  $HNO_3$  and titrated with 0.1%  $NH_4CNS$  by the Volhard method. W. O. P.

**A method for the photometric determination of small amounts of adrenaline.** G. N. Thoms. *Praktika (Hlad. Phenom)* **7**, 17-21 (1932). Detn. of adrenaline by the Atherton-Suddell colorimetric method may be inaccurate if any  $HCl$  present is not carefully neutralized. The  $Cl$  liberated during the analysis alters the intensity and shade of the color. The concn. of the soln. is equally important, since from 0.02% there is no ratio between color intensity and the adrenaline content of the liquid. A standard color scale may be prepd. from basic salts of  $Co$  and  $Au$ . With the Pullrich photometer it is found that this color reaction does not follow Beer's law between certain limits of concn. Above 0.01% the coeffs. of extinction corresponding to the permeability observed are not proportional to the concn. which should fall between 0.002 and 0.006% if exactness is expected. Absorption and extinction curves are given, plotted for a series of observations on a 0.005% adrenaline soln. for a thickness of reservoir of 10 mm. From these constants may be calcd. the content of an unknown soln. according to the relation  $C_x/C = L_x/L$ . Lucien Y. Dyrenforth.

**Color reactions obtained with metadinitrobenzene in alkaline media.** Marcel Peronnet and Rene Iruhaud. *J. pharm. chim.* **18**, 339-43 (1933). (1) The aldehydes

*HClO*, chloral, *B.H.*, vanillin give a violet color with *m*-dinitrobenzene (1) in alk. medium only upon warming. To 5 cc of 0.1% of 1 in 95% alc. add 1 cc 10% NaOH on warming a pink color is seen on adding now a little of the aldehyde, the color turns violet. (2) Of purine substances, *urea acil* alone shows the test. To a crystal of uric acid add a little of 1, then 1 cc of 10% alc. NaOH a violet color is formed. (3) Certain amino acids (*B*) glycine, lysine and *l*- $\beta$ -alanine (C) give the test. Dis-

solve 0.10 g. *B* in 2 cc 10% NaOH and overlay without mixing with 2 cc of alk. soln of *A* an evanescent but strongly violet ring is obtained, notably with *C*. Or, with glycine mix 0.10 g with 2 cc alk. soln of *A* and add 1 or 2 particles of NaOH violet streaks are seen, a blank test shows a merely yellowish color. S. Waldhoff.

Recovery of  $\text{Pb}$  from metallic iodides (McClary, Deering) 6

## 8 MINERALOGICAL AND GEOLOGICAL CHEMISTRY

L. CARL WILKIN AND J. J. SCHAIKIN

**Chemical migration II** Roland Blanchard *Eng. Mining* 134 (2) 5 (1933) cf. C. 1 27 387. The distribution and behavior of Au and Ag in the Edie Creek and Golden Kidges lodes indicate: (1) irregular deposition a primary Au without important subsequent migration, (2) much concn. due to weathering of the lode with subsequent transportation by gravity or by circulating ground water along fissures, (3) chemical migration because the Au was taken into solution by ground waters and subsequently reprecipitated, and (4) a combination of 2 or more of the conditions mentioned above. Each of these is discussed. Neither hypothesis (1) nor (2) satisfactorily explains all conditions found. W. H. Boynton.

**The Nigerian gold field** W. R. *Mining Mag.* 49 (2) 52 (1933). Nearly the entire area consists of an Archean complex in which chlorite and mica schists are of the most importance to the miner. It is probable that the Archean dikes are a product of hydrogenesis and are not generally of direct igneous origin. The industry is still confined to the alluvial type. A. W. Fairbank.

**The lime resources of Kenya Colony** G. H. Graham Jones *Kenya Colony Dept. Agr. Bull.* 12, 15 pp.

(1932). Deposits of limestone are known in numerous localities and coal beds are widely distributed along the coast. The material ranges from calcareous tuff to marble and the  $\text{CaCO}_3$  content from approx. 5 to 98%, with  $\text{P}_2\text{O}_5$  0.30 to 5.80% in material containing more than 60%  $\text{CaCO}_3$ . K. D. Jacob.

**Salt domes, gases and petroleum** V. I. Luchitskii *Mineral. Sbornik* 8, No. 4, 12 (1933). Test borings in the Pomen and Lachek regions, North Poltava, disclosed deposits of rock salt and gas. The high elevation of the salt deposits above the sea level indicates doming. Shatskii. Petrology with the salt domes of U.S.A., the deposit must be of great magnitude and overlie petroleum deposit. The presence of He in gases is suggested by the location of the deposit in Permian Carboniferous strata. Chas. Blum.

**Seefeld diarsenite** Guido Hradil *Pharm. Ztg.* 78, 109 (1933) cf. Totome (C. 1 27, 5688). W. O. I.

Monobite lust from the Flychind zone of the East Carpathian. Casimir *et al.* 22

## 9 METALLURGY AND METALLOGRAPHY

D. J. DEMAREST, OSCAR E. HARDER AND RICHARD RIMBACH

**Application of x rays to metallurgy** C. A. Kuryumov *Dokl. 1933*, No. 5, 411. A theoretical discussion and review of the literature with 36 figures and 3 references. S. I. Miodorsky.

**Ore treatment at the Lake View and Star** I. B. Steven *Mining Mag.* 49 201 (2) 19 cf. *Western Australian Metallurgical Practice* 1906. The Au in the sulfide ore at Kalgoorlie occurs (a) in the free state (b) as tellurides and (c) associated with pyrite. The proportion of the total Au which occurs in each of the ways varies considerably in the different lodes but for any treatment process to be satisfactory it must be able to treat all of them equally well. Three methods of treatment used since 1910 are compared. In the second plant the ore was crushed dry, and all of it was roasted and cyanided. In the third plant just completed, wet crushing is used and flotation takes the place of gravity concn. Over 90% of the mineral content of the ore is concd. into 7% of concentrate and 95% of the ore is discarded without cyanide treatment. The flotation concentrate like the gravity concentrate in the first plant is roasted, but without the addition of fuel as the S content is now sufficiently high, it is then cyanided as before. In the first plant the free Au was caught on the Wulley table, but with the flotation process a better saving has been effected by using corduroy strikes before flotation. In pptn. of dust coarser than the imported variety is used with satisfactory results.  $\text{Pb}(\text{NO}_3)_2$  amounting to 10% of the wt of the Zn is added before chlorination. No acid treatment is given to the ppt. which passes direct to cast iron muffles for roasting. An additional life has been given to the muffles by filling them with renewable chrome steel bottom contg. 27% Cr. A. W. Fairbank.

**Influence of the concentration of ores by flotation on metallurgy** I. Prost *Rev. universelle chim.* 9 521 (9)

1933). The great progress made in the metallurgical field during the last 15 years due to the application of flotation processes for concg. ore and especially of selective flotation has made possible the working of formerly neglected low grade ore. The various methods in use in non-ferrous metallurgy are discussed. Thirty six references. M. Hertenheim.

**The clarification of ore dressing effluents** G. Garth *Arch. Freiberg. Bergbau. Verh. Metallhuttene* 1 11 (4) (1933). In the effluent from a plant treating tin ore, the settling rate of solids was increased by the addition of  $\text{Ca}(\text{OH})_2$ ,  $\text{CaCl}_2$ , dextrin or Irish moss. The best results were obtained with 0.026 lb  $\text{Ca}(\text{OH})_2$  plus 0.05 lb Irish moss per ton of water treated. John C. Attwood.

**The applicability of low temperature reduction to certain Ontario iron ores** J. R. Gordon and O. W. Ellis *Can. Mining Met. Bull.* No. 259, 68 (725) (1933).

Detailed data are given on the reducibility, grade of concentrate and recovery of Fe at various temps. of reduction for various times for various ores ground to various sizes. The highest grade ores were the most readily reduced. The order of reducibility is determined chiefly by the quantity, distribution and character of their impurities. Variations in the size of ore have much less effect on the reducibility of high grade ore than of low grade ores. Lengthening the time of reduction is effective only in dense impervious ores. Magnetic concn. of the raw ore prior to reduction is preferable to concn. of the material reduced from unconc'd ore. A. H. Emery.

**Gold its relationship to mankind** R. C. Rowe *(Can. Mining J.)* 54, 122 (7) (1933). A brief review.

W. H. Boynton. **Recovery of silver from Kongsberger slime by cyaniding** R. Støren *Arch. Freiberg. Bergbau. Verh. Metallhuttene* 1 15 54 (1933), cf. C. 1 26, 3758. Ag recovery started

at this mine in 1815. Since 1901 over 200,000 tons of slime have been leached. History of the mine, theory and technology of the process are included. J. G. Attwood

**The separation of lead and zinc in oxidized ores, smelting products and residues.** G. Grusser. *Arch. Erzbergbau Erzverh. Metallhüttenw.* 1, 131-45 (1931).—Pb in oxide form is volatilized at 800-800°, without influence by ZnO, CaO, MgO or Al<sub>2</sub>O<sub>3</sub>, but SiO<sub>2</sub> forms Pb silicate and hinders volatilization. A chloridizing treatment produces PbCl<sub>2</sub> which readily volatilizes, forming also Na<sub>2</sub>SiO<sub>3</sub>, which is not harmful. Pb in sulfate form when treated with NaCl volatilizes at 450-800°. Pb as silicate is liberated by NaCl at 800°. ZnO is not affected by NaCl below 1900°, does not volatilize below 1300°. ZnSO<sub>4</sub> readily forms ZnCl<sub>2</sub> which is very volatile, but is oxidized in presence of PbO to ZnO and PbCl<sub>2</sub>. Small amts. of C reduce PbO to Pb and interfere with volatilization. PbSO<sub>4</sub> is not affected. Strong reducing agents interfere seriously with chloridizing volatilization of PbSO<sub>4</sub> at 800°. Sulfides of Pb and Zn have no harmful effect in oxidizing or neutral atm. John G. Attwood

**Preparation of vanadium from aegirine.** M. B. Zapadinski and V. M. Zhogina. *Sovetskoe Metal* 1932, No. 5, 68-73. Extn. of V with acids is too low because of low soly. of aegirine. Roasting with addn. of 15% of chalk or lime at 850-950° followed by treatment with acid resulted in 80-90% recovery. Pure iron vanadate was obtained by adding Fe and neutralizing the soln., but the ratio V:Fe was too low, and the process can be applied only to ores with low P content. For high-P ores a method was developed whereby all the V is sepd. from Fe to obtain V<sub>2</sub>O<sub>5</sub>. Charge roasted with lime or chalk is dissolved in HCl, the soln. neutralized with CaO, and the ppt. treated with ammonia. By this treatment 92-95% of the V is extd. The soln. is then evapd. to dryness to obtain V<sub>2</sub>O<sub>5</sub>. The ammoniacal solns. are free from P, Al, Fe, etc., and contain only a small amt. of SiO<sub>2</sub> and traces of Ca. B. N. Daniloff

**Investigation of the conditions for the chloridizing volatilization of metals.** Paul Zielinski. *Arch. Erzbergbau Erzverh. Metallhüttenw.* 1, 31-41 (1931). Samples were exposed in a glass or porcelain boat to a stream of specially purified Cl and heated by an elec. muffle. For PbO chloridizing starts at room temp., for SnO<sub>2</sub> at 1000°, for SnS, FeS, Ag<sub>2</sub>S, CoS, Cr<sub>2</sub>S<sub>3</sub> and CuS below room temp.; for Ni<sub>2</sub>S<sub>3</sub> at 150°. Chloridizing is complete for PbO at 400°, for SnO<sub>2</sub> at 1400°, for SnS at 130°, FeS and Ag<sub>2</sub>S at 250°, CoS and Cr<sub>2</sub>S<sub>3</sub> at 700°, Ni<sub>2</sub>S<sub>3</sub> at 550°. Both CuCl and CuCl<sub>2</sub> are formed. CuCl reaches a max. of 22% of the sample at 100°, at 570° the sample is 100% CuCl<sub>2</sub>, at 880° CuCl<sub>2</sub> has reverted to CuCl. Phys. condition of the sample is important; pptd. PbS or ZnS is completely chloridized at 200° earlier than pure galena or sphalerite. In the presence of small amts. of water and C, chloridization is accelerated. The process is more complete at a given temp. where more of the surface of the sample is exposed. An analytical detn. of impurities in Al through volatilization of the chloride of the metal is impossible because of the chloridization and volatilization of the oxides and inclusions before the Al. Z. takes advantage of this to purify Al. Cl can be used to protect Mg from N which thickens it and makes casting difficult. NaCl begins reacting with metals and oxides at 500°, with sulfides at 350°. The presence of S makes the oxides much easier to chloridize with NaCl. Z. shows that this process can be successfully used on a difficult Sn ore. John G. Attwood

**Bralorne mill of Bralorne Mines, Limited.** Fred E. Gray. *Can. Mining Met. Bull.* No. 259, 683-6 (1933).

A Au-bearing (75-80% free) quartz congt. a very small amt. of Ag is passed over blankets, and the tails are floated. Amalgamation (traps and blankets) recovers 74% of the Au and flotation 21% more. Alden H. Emery

**The Hoge mill.** Frederick G. Moses. *Eng. Mining J.* 134, 422-4 (1933).—A 50-ton plant treats Au ore formerly unworkable by all-flotation methods. Mill recovery is 97%, with heads averaging \$12 per ton and tails \$0.00.

W. H. Boynton

**The Hardinge-Hadsel mill at Antamok.** J. B. Martin. *Mining J. (Phoenix, Ariz.)* 17, No. 10, 3-4 (1933). A 125-hp., 24-ft.-diam. Duplex Hardinge-Hadsel mill for grinding in a single operation is used; 200 tons per day of ore passing a 12-in. grizzly is ground to 65% minus 200-mesh. The mill is stated to operate satisfactorily even on oxidized ore, and without any large pieces of rock to act as a grinding medium. A. W. Furbank

**The Nkana smelter.** A. D. Wilkinson and F. L. Bosqui. *Mining Mag.* 49, 265-78 (1933). Two reverberatory furnaces, each 90-ft. long and with an inside width at the slag line of 26 ft., handle a charge of raw concentrates, mat shell and converter slag shells, together with holding-furnace slag and dust from the waste heat boilers. At present, no flux is necessary. The concentrates charged run Cu 54.9, S 23.3, SiO<sub>2</sub> 1.76 and Fe 9.09%. Flow-plan and photograph illustrate the layout of the furnaces and the two 13-ft. by 30-ft. Pierce Smith converters. A. W. Furbank

**Practical notes on amalgamation.** Geo. Holcombe. *Chem. Eng. Mining Rev.* 25, 105-6 (1933). Hard Cu plates should be employed and carefully prepd. Na amalgam is invaluable in case stamps develop. The proportions should be 97 parts Hg to 3 of Na and should be used at about 82°. When all of the Na has been absorbed, the contents of the retort are poured and the amalgam is obtained in a thin sheet on cooling. It should be ground and placed in a well stoppered glass jar. The addn. of a 0.5% cyanide soln. at a rate of 1 drop per min. where Hg has been added to the mortar box has a marked effect in retarding the staining of the plates. Dressing is then required less often and the greater efficiency of the amalgamation outweighs any possible loss of Au by soln. W. H. Boynton

**Tellurides.** W. E. Johnston. *Eng. Mining J.* 134, 412-13 (1933), cf. C. A. 27, 1759. Discussion.

W. H. Boynton

**An investigation of the performance of hot-blast stoves at the Petrovskii and Dzerzhinskii plants.** N. B. Rulla. *Dokl. 1933*, No. 5, 6, 14-30; No. 7, 20-9. A study was made of data on construction and operation of blast furnace hot stoves in order to find optimum conditions in regard to economy of performance. S. I. Madorsky

**Study of the operation of a crucible furnace of three tons capacity.** M. L. Gasquard. *Rev. l'industrie moderne* 27, 267-72 (1933). A complete thermal balance of a 3-ton crucible furnace is given, together with the compn. of the charge and materials obtained in the slags. The development of a special refractory lining is advisable. M. H.

**Smelting operations at Roan Antelope Copper Mines Limited.** Charles R. Wraith. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. 511, 25 pp. (1933). Cu is contained in the ore as chalcocite, chalcopyrite and bornite.

Chalcocite predominates in the ore body now being mined. The mat contains Cu 79.00 and Fe 0.5%, almost pure Cu<sub>2</sub>S. Limestone is added to supply a deficiency of bases for producing a satisfactory slag; it also counteracts to some degree the thickening influence of the Al<sub>2</sub>O<sub>3</sub> present. Expts. in a 4- by 6 ft. reverberatory showed (1) that a Ca silicate slag congt. up to 15% Al<sub>2</sub>O<sub>3</sub> and having a silicate degree approaching a bisilicate was sufficiently fluid to be handled and to permit satisfactory sepn. of the mat, and (2) that mat congt. 80% Cu could be blown in a converter without the addn. of extraneous heat during the blow but the converter would have to be heated between blows. Outstanding features contributing to simplicity of operations, high efficiency and low costs are: (1) high Cu fall (57% of the wt. of concentrate smelted), (2) low fuel ratio (averaging 15.5%), (3) high mat fall (70% of the wt. of the charge), (4) low slag (26% of charge), (5) low flux burden (6% of wt. of concentrate), (6) high furnace capacity, (7) simple converter operations (no SiO<sub>2</sub> flux and no slag) and (8) high converter capacity (short blow). The flow sheet is described in detail, with analyses and operating data. Alden H. Emery

**Chlorine smelting with chloride electrolysis.** E. A. Ashcroft. *Bull. Inst. Mining Met.* No. 350, 65 pp.

(1933) All the metal in sulfide ore are converted to chlorides with  $\text{Cl}_2$  and reduced by pptn with Zn. The fused  $\text{ZnCl}_2$  is electrolyzed to produce Zn and Cl. Elemental S is recovered. The history of the development of the process by Swinburne and its subsequent use is discussed. Flow sheets are given and individual steps, including removal and separ. of impurities, are described in detail. One lb Zn is obtained per kw hr. Costs are estd at \$3.16 per ton Zn from 30% concentrate without credit or cost for by products. Alden H. Emery.

**An experimental combination of shaft roasting and reverberatory smelting.** Frederick Latt and J. P. Cooper. *Am Inst Mining Met Engrs, Tech Bul No 510*, 8 pp (1933). The small reverberatory alone smelted 16,678 lb per 25 hr with 797 gal oil. In connection with a roasting unit 30,500 lb were smelted per 24 hr with 62 gal oil. The increase due to the temp at which elements enter the melting chamber (1170 F) and to a lesser extent to the hot gas from the roasting shift. When operated alone, the shift capacity was 10 ton per 24 hr and produced a dense concentrate. Alden H. Emery.

**The influence of impurities on the roasting of sphalerite.** Franz Fennrich. *Arch Elektroan Erzaufbereit Metallhütten* 1, 1-10 (1931). Roasting always begins at 500°. Ignition is retarded by FeS and FeS<sub>2</sub> is unaffected by PbS and CuS. CuS adds to a ZnS-FeS-PbS-SnO<sub>2</sub> mixt lower the ignition temp. When mixed with 20% of the commercial Sphalerite completely roasted at the following temp: CuS, 650°; FeS, 680°; FeS<sub>2</sub>, 690°; PbS, 700°. The value hold true for complex mixts. Homophen FeS retard the roasting more than do pyrrhotite. Sulfate formation is promoted by the presence of FeS, PbS, FeS<sub>2</sub>, CuS in order of increasing effectiveness. SnO<sub>2</sub> is ineffective. The highest sulfate content has at about 1000. Above 900° very little is found. When a roasting temp of 1000° is exceeded part of the Zn become mol in Murratt oil. FeS causes the largest Zn loss through formation of ZnO-FeO. This Zn exceeds loss through sulfate formation. Loss of Zn in the presence of PbS and CuS are caused by intermixing. In complex mixt greater Zn loss occur than would be anticipated from the constituent because of formation of low melting alloys. John G. Attwood.

**Some practical considerations in a small jobbing foundry.** B. G. G. *Foundry Trade J* 49, 20-21 (1933). An outline of some of the methods used in a gray Fe foundry mfg high grade castings such as globe valves. Down Schrad.

**Developments in the iron and steel industry.** W. H. Burr. *Iron Steel Eng* 10, 20-21 (1933). W. H. Burr.

**What phase of steel making is most responsible for the quality of steel products?** Theodore L. Fos. *Iron Steel Inst* 10, 8-11 (Oct., 1933). An historical address. W. H. Roynton.

**Effect on various steels of hydrogen at high pressures and temperatures.** N. P. Inglis and W. Andrews. *Engineering* 136, 11-14 (1933). See C. I. 27, 290.

**Influence of thermal conductivity of metals on their utilization in the chemical industry, particularly in the manufacture of acids and explosives.** Zdenek Stefan. *Chemie et Industrie Special* No. 9017 (June 1933). A general discussion dealing with principal rules affecting the thermal cond of metals, detn of the influence of the choice of metal on the heat transmission, detn of the relation by means of which to select the metal having the most advantageous properties, satisfactory resistance to corrosion, optimum mech properties, max thermal cond, principal metals and alloy used in the chem industry, particularly from the standpoint of thermal cond and the possibility of giving them the shapes required in the mfg of acids and explosives. A. P. C.

**X ray investigation of the nature of change of structure in a metal, resulting from deformation at high temperatures.** I. I. Bikhmetev, M. D. Vozdvizhenski, S. I. Gubkin, G. I. Kosolapov and B. M. Rovinski. *Vitt*

*Forschungsin Luftfahrtmaterialprüfung* (U. S. S. R.), No 1, 131 pp (in German 129-31) (1933), cf C. I. 25, 5377. An exhaustive study made by means of X-ray examn of the changes taking place in the structure of duralumin when deformed under pressure or impact at high temps. It was found that recrystall rate is equal to rate of deformation %, under the following conditions: at 300° 0.6 mm sec, 50, 0.5° 0.75-400, 1.5 slightly greater than 1.24-450, 1.24° 2000-300, 1.24° 2000. Where deformation has reached 60-70%, an anisotropy of structure in the alloy can be observed not only where the deformation takes place at room temp, but at high temp as well and not only where it is high (under impact), but where it is small (less than 0.001%). This is also true in case where recrystall is not experimentally observable. Duralumin samples deformed at 150° and at room temp are similar in structure. Numerical table, diagrams, curves and photomicrographs are given. S. I. Madorsky.

**A flat-bend endurance testing machine of the D. L. V. and results obtained with it.** Kurt Matthies. *Metallurgisch* 12, 48-50 (1933). C. I. Madorsky.

**Testing sheet metals.** M. A. Schwarz and K. Christoph. *Metallurgisch* 12, 47-48 (1933). For the testing of thin sheets which are to be cold worked the tensile, hardness and bend test are not as satisfactory as a ductility test such as the Erichsen. The ductility, tensile strength and elongation are related as follows: ductility in mm  $\times 10$  (thickness)  $\times$  (tensile strength)  $\div$  2 = elongation. S. C. (1)  $\div$  1. The ductility of S material were detd on an Erichsen app and calculated from their tensile strengths and elongation and the result agreed fairly well. C. I. Madorsky.

**New uses for thin films.** James D. Edwards. *Ind Eng Chem, Anal Ed* 11, 28-30 (1933). Properties and use of Al bearing thin film of oxide in dielectric. I. J. C.

**The cause and effect of the solution of salt in metal.** Thadde Peczkalski. *Combustion* 107, 2-9 (1933). Expt with Cu and Fe treated in CuCl, KCl, KI and BaCl<sub>2</sub> showed that cementation of metal in contact with a salt at high temp is accompanied by soln of the metal in the salt. The principal mechanism of attack is the penetration into the metal of products of the salt. J. P. A.

**Reasons for differences in the results obtained by various authors for the solubility of copper in aluminum in solid state.** P. Ya. Seldin. *Am Inst Metallurgichesk* (Leningrad) 6, 7-9 (1933). A comparison made between the result obtained by S. and Annenkov (C. I. 21, 5801) and those of Divin and Kichardson (C. I. 20, 21-22) and the discrepancy is explained on the ground that in the case of the latter investigators, because of insufficient time (0.5 hr) of cooling the alloy equil was not reached. S. and A. kept the alloy at the tempering temp for a week. There was also a difference in the size of the samples, it being smaller in the work of S. and A. S. I. Madorsky.

**Tests of cold pressed screws.** J. Vodicka. *Chemie et Industrie Special* No. 67 (Sept. 1933). A metal exhibiting considerable P and S segregation is unsuitable for mfg cold pressed screw. Slight or moderate segregation does not cause defect on pressing. When the center of segregation is symmetrically placed relative to the circular section of the screw the latter may break between the body and head. By cold pressing the screw and following a definite mfg process a spherical zone obtained in which there is max deformation of the ferrite grains between the body and head. Corrosion with 1% HCl can advantageously be used to examine the zone of deformation in the head. The changes in the mech properties can be detd from the extent of corrosion with 1-2% HCl. To ascertain the condition of the metal during pressing of the head, only the Rosenham etching method is suitable. The Hevn etching method cannot be used because it also brings out the effects of cold working, which does not completely mask segregations. From the result of the Rosenham etching, the procedure of pressing the

head may be modified so as practically to eliminate the possibility of separ. of the head from the body.

**Gas-free metals used in x-ray tubes.** W. D. Coolidge and E. E. Charlton. *Metal Progress* 24, No. 5, 36-40 (1933). Pt has been replaced by W, Mo and Cu, adequately degassed by long heating in H<sub>2</sub>. W. A. Mudge

**New method for determining the thickness and quality of zinc coatings on galvanized iron wires.** A. Glazunov. *Chimie et Industrie Special No.*, 688-90 (June, 1933).

A 20-30-cm. length of wire is covered with wax, leaving about 3-4 cm. bare near the center. The wire is immersed vertically in a coned. ZnSO<sub>4</sub> soln and is connected to the pos. pole of a source of d. c.; a cylindrical Pt cathode is used. The voltage and amperage are read. During soln. of the pure Zn coating the amperage and voltage remain const., when the layer of Zn-Fe alloy begins to dissolve the voltage increases. When the alloy has completely dissolved the voltage remains const., but at a much higher value than at the beginning of the expt. The dimensions of the wire, amperage and time being known, the thicknesses of the pure Zn coating and of the Fe-Zn layer can easily be calcd.

A. Papineau-Couture

**Preparation and etching of galvanized wire for metallographic examination.** Ladislav Hajda and Stephan Popole. *Chimie et Industrie Special No.*, 700-1 (June, 1933). The following treatment was found to give very distinct structures under the microscope: mounting of sample in chomite, polishing with MgO suspended in denatured alc., etching by means of a dil. Kourbatoff reagent (1 vol. of 4% HNO<sub>3</sub> in AcO is mixed just prior to use with 10 vol. of a mixt. of equal vols. of MeOH, EtOH and iso AmOH).

A. Papineau-Couture

**Removal of pickling fumes.** W. Fischer. *Oberflächentech.* 10, 234-7 (1933). Fumes originating in the pickling process, being more or less injurious to health, must be removed from the work rooms. Hoods over the tank and exhausters are usually arranged, or the fumes removed with a spray of atomized water. Arrangements are described.

M. Hartenheim

**Use of nitrophenols as etching reagents for iron carbides and ferromanganic carbides.** A. Glazunov and V. Petak. *Chimie et Industrie Special No.*, 691-3 (June, 1933).

Etching of *o*-, *m*- and *p*-C<sub>6</sub>H<sub>4</sub>(OH)NO<sub>2</sub> (I) in NaOH or KOH soln. was studied comparatively with that of Le Chatelier's reagent (25 g. NaOH and 2 g. C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> per 100 cc.) on hypereutectoid steel (C 1.3, Mn 0.8%, ) white (Fe-C 5, Mn 1%, ) and ferro-Mn contg. up to 14% Mn. With *o* I, all the I sepd. from the soln. and could not be dissolved, even on boiling, showing that the etching was reduced exclusively by the alkali present in the reagent.

I gave practically the same results as Le Chatelier's reagent. With *p*-I, the carbide was bicolored (green and d.) and the pearlite remained white, even after 5 mins. etching. With white cast Fe (1% Mn) the cementite did not appear heterogeneous, i. e., the initial solid soln. of Mn carbides decomps. into 2 phases, the decomposition taking place in such a manner that the  $\alpha$ -Fe<sub>3</sub>C solidification (below the A<sub>0</sub> point) does not dissolve or solves only to a very slight extent in the Mn carbide.

A. Papineau-Couture

**The effect of thickness on the crystal arrangement of rolled sheet aluminum.** G. V. Vargha and G. Wasser. *Metallwirtschaft* 12, 511-13 (1933). Sheet Al was cold rolled to 5 mm. thickness and various layers were examined by the x-ray diffraction method. The layers were obtained by machining and etching away parts of one or both sides of the sheet. The orientation in the center of the sheet was entirely different from that at the surface. The center corresponded to the crystal position (110) parallel to the rolling plane and [112] parallel to the rolling direction. The surface corresponded to the crystal position (100) parallel to the rolling plane and [110] parallel to the rolling direction, but the scattering was much weaker in this case. The surface orientation was practically unchanged to a depth of 1.2 mm. and at 1.6 mm. the orientation of the center was obtained. The center

orientation of the 5 mm. sheet was obtained throughout in 1 mm. and thinner sheets, the surface being less sharp than the center. These results are similar to those obtained on hard drawn wire. Thirteen references. C. F. M.

**Factors governing the life of lead in chemical plants.** R. S. Russell. *Chem. Eng. Mining Rev.* 25, 421 (1933). Phys. properties and the analysis of a good chem. Pb are given and the corrosion-resisting alloys of Pb briefly discussed. Pb-Cu and Pb-Fe alloys are the most promising of these. Tests are being conducted, with results, so far, insufficient for definite conclusions. A bibliography is appended.

W. H. Boynton

**The lattice constants of pure iron and iron-carbon alloys at temperatures up to 1100°.** Hans Esser and Georg Mueller. *Arch. Eisenhüttenw.* 7, 265-8 (1933). By means of a specially developed x-ray camera exposures were made in a vacuum at different temps. on the same film whereby the picture at room temp. was used as standard for the detn. of the lattice const. Electrolytic and carbonyl iron showed that the lattice parameter of  $\alpha$ -iron does not change linearly with temp., the curve shows a discontinuity at the Curie point which is different with different irons. The  $\gamma$ -phase showed in all samples the increase of the lattice const. to be linear with temp. The expansion values found in this manner were higher than those given usually from dilatometric measurements. Fe-C alloys within the  $\gamma$ -range do not show linear change of the parameter as function of C content; hypo eutectic steels showed at 720° an increase of the lattice parameter with increasing C content, contrary to the Fe-C diagram. Eight references.

Downs Schaaf

**Influence of arsenic and antimony on cast iron.** P. Piwowarsky, J. Vladescu and H. Nipper. *Arch. Eisenhüttenw.* 7, 323-7 (1933). Cast iron melts with addns. of As up to 2% and Sb up to 1.2% were investigated. Arsenic has very little influence on quantity and formation of graphite and structure. Bending and tensile strength are increased at first but decrease at higher contents. Brinell hardness, elasticity modulus, wear resistance and particularly corrosion resistance against acids increase with As content. Impact strength and endurance impact no. are reduced by As but not quite as much as by P and S; the effect of the 2 latter elements is more pronounced in the presence of As. Sb seems to be sol. in cementite and counteracts graphite formation. Bending and tensile

strength, deflection and toughness are greatly reduced by Sb. Brinell hardness, elasticity modulus and wear resistance are increased. Corrosion resistance depends on the attacking medium. Further test with reduction of iron ore contg As and Sb seem to point to the fact that addition of As to cast iron is much more harmful than the content of As which originates from the iron ore in the cast iron. M. Hartenbach.

**Thermal conductivity of wrought iron steel, malleable cast iron and cast iron.** J. W. Donaldson. *Iron Steel Inst. (London) Advance copy No. 6*, 20 pp. (Sept., 1933).

The thermal cond. of wrought iron is approx. 0.17 cal per cm per sec. at 100° C. and decreases with increasing temp. The thermal cond. of steel decreases with the C content: a value of 0.100 cal per cm per sec. was obtained for a 0.10% C steel and 0.117 cal per cm per sec. for a 1.00% C steel; the decrease due to the influence of C has on the structure in producing relative units of ferrite, pearlite and cementite. Data indicate that the thermal cond. of ferrite is higher than 0.141 cal per cm per sec. hitherto adopted, and that pearlite has a thermal cond. of approx. 0.124 cal per cm per sec. Blackheart malleable iron with a structure of ferrite, temper C and a small proportion of pearlite, has a thermal cond. of 0.100 cal per cm per sec. at 100° C. and whiteheart malleable Fe, with a structure of pearlite, temper C and a small proportion of ferrite, a thermal cond. of 0.111 cal per cm per sec. The influence of Si to lower the thermal cond. especially in cast Fe-P produces a slight decrease in thermal cond. in gray cast iron. Five references.

C. B. Jones.

**The  $\alpha$   $\gamma$  transformation in the ternary systems of iron.**

W. Koester and W. Fonn. *Arch. Eisenhütten* 7, 19 (200/1933). The possible form of ternary Fe alloys in the heterocentron ( $\alpha + \gamma$ ) space of the equilibrium are investigated and represented by a dimensional model. There are three models of ternary Fe alloy corresponding to the multian on presence of binary alloy with the  $\gamma$  field; they can be represented by 1) melt +  $\alpha + \gamma$ , melt +  $\alpha + \delta$  (2) melt +  $\alpha + \gamma + \delta$  the 4 phase reaction and (3)  $\alpha + \gamma + \delta$  in melt +  $\gamma + \delta$  at the crystal that is exchanged in the transformation. The 3 basic diagrams permit the derivation of all other cases; they occur under limited only, or when a third crystal type enters. The 3 possibilities and their representation in the space diagram are explained at length. Twenty-four references. M. Hartenbach.

**Final examination of the second series of iron and steel specimens exposed at Halifax N.S. for a period of ten years.** J. Newton Friend. *Def. and Ind. Research Thirteenth (Interim) Rept. Comm. Int. Conf. Eng. Det. notation of Structures in Sea water*, 7-20 (1933). High Ni steel show the greatest corrosion resistance.

**Final examination of the second series of iron and steel specimens exposed at Auckland for a period of 10 years.** *Ibid.* 21. High Ni steel show greatest corrosion resistance. **Final examination of mild steel plates coated with various protective media and exposed to sea air at Southampton docks 1924-31.** *Ibid.* 31. J. L. Greck.

**Heat resistant steel.** S. S. Steinberg, S. I. Gutermin and I. P. Bernova. *Tekhn. Sci. Ser. 1* 41 (1931). *Chem. Zvesti* 1932, I, 1910. Resistance to oxidation at high temps is imparted to steel by Cr and Si. Mo increases the resistance only slightly. A steel contg Cr 5, Si 1, and Mo 0.6, oxidizes readily; a ordinary C steel increasing the Si to 0.6, decreasing the Mo and leaving the Cr unchanged render the steel fireproof. A steel contg Cr 8% and Si 1% is unsatisfactory unless it also contains 2% Mo. When the Cr content is 8% the steel must not contain less than 0.5% Si. 1% Si suffices in the presence of 14% Cr with 18% Cr Si is unnecessary. Likewise steel high in Si is fireproof without Cr. At low

Cr content, increasing the C impairs the quality of the steel. At higher Cr content it has little influence.

M. G. Moore.

**Residual metals in open hearth steel.** C. J. Williams and J. D. Sullivan. *Metals & Alloys* 4, 151 (2/1933), cf. C 1 27 51. A continuation of the study of the amt. of residual Mn, Cu, Ni, Cr and Sn in open-hearth steel sample from some 18 different companies in the U.S. and Canada. Downs Schaaf.

**Influence of the quenching temperature on steel hardening phenomena.** H. Essert and H. Mayer. *Arch. Eisenhütten* 7, 519 (22/1933). The influence of cooling velocity on the temp. of magnetic transformation of  $\alpha$  iron and cementite was investigated by the method of Essert-Spenle. Pure Fe showed that the magnetic transformation has a certain capacity for undercooling, and in steel it was found that formation of martensite requires cooling not only from a temp. range above  $A_{c1}$  with a definite velocity but also from a temp. which is detd. by the C content. This is explained by the fact that residual ferrite and cementite which would serve as crystal germs for formation of pearlite during quenching dissolve in martensite only at sufficiently high temps. M. H.

**Quenching steel in hot baths.** H. I. Doesch. *Metal Progress* 24, No. 3, 24 (9/1933). SAE steels 1045 and 150 give lower ductility for equal strength when quenched in an appropriate hot bath as compared to regular quenching and tempering. W. A. Mudge.

**The structure of carbon steel at elevated temperatures and under reduced pressure.** H. I. Pablow and I. D. Parker. *Mech. Eng. Expt. Sta. Bull. No. 53*, 16 pp. (1933). A vacuum furnace design is described which permits of microscopic observation of specimens at temps. up to 1000°. It is shown that recryst. temp. of steel vary with the pressure in much the same manner as the boiling temp. of liquid. Downs Schaaf.

**X-ray investigation of the aging effect in quenched carbon steels.** Zemp Nishiyama. *Science Repts. Tohoku Imp. Univ. Int. Ser.* 22, 563 (9/1933). Specimens of Swedish steel were machined in the form of a rod, quenched by the water jet vacuum method and then x-ray diffraction pattern of the specimen kept at 49°, were obtained. The result shows that age hardening at room temp. or below 100° is due to the low temp. formation of tetragonal martensite to the harder cubic martensite with the transformation more conspicuous in low C steel.

J. G. Vanden Bosch.

**The composition of the carbides in chrome steels.** L. Maurer, Th. Dörning and H. Buttg. *Arch. Eisenhütten* 7, 247 (1933). The carbides in steels with 0.1-1.0% C and 0-5% Cr were dissolved either by acid or electrolytically. The existence of Cr-Fe carbide was found of which the Cr carbide components had the compns. Cr<sub>3</sub>C and Cr<sub>7</sub>C<sub>3</sub> the former occurring in steel with 0.5% C the latter in steel with higher Cr content. Cr carbide of the compn. Cr<sub>3</sub>C, Cr<sub>7</sub>C<sub>3</sub> or Cr<sub>7</sub>C<sub>3</sub> could not be found. The result of the investigation indicated also the possibility of detg. the structural arrangement and the distribution of Cr between carbide and ferrite. M. H.

**Mechanism of breakdown of steel III.** Masao Kuroda. *Bull. Int. Phys. Chem. Research (Tokyo)* 12, 511 (7/1933). *Abstracts* 4 (in English) published with *Sci. Super. Int. Phys. Chem. Research (Tokyo)* 22, Nos. 400-3; cf. C 1 27 692. The mechanism of the breakdown of C, soft and hard steel has been microscopically examined. It is explained that the steel not only yield by slipping of the cleavage plane but that it is deformed by plastic cracking. The lines considered as cracks, and passing through several grains, seem to be independent of the orientation of each grain. Thus in some remarkable cases, the cracks run along the peripheries of pearlite. As previously reported the yield point appears when the stressed member in steel is transformed from honey-comb boundary structure of grain into ferrite. When this boundary structure is broken, further stress breaks ferrite along line joining these cracks of the boundary structure. These lines must be crack lines in ferrite, the internal

deformations in grains are naturally considered due to slipping of cleavage planes. K. Konda

**Practical plasticity problems.** Geo. M. Eaton. *Mech. Eng.* 55, 557 60(1933).—The opportunities afforded by a study of the plasticity of steel during fabrication are pointed out. L. W. T. Cummings

**Prevention of flakes in alloy steels.** H. H. Ashdown. *Metal Progress* 24, No. 5, 13 17(1933). Flakes are internal cracks caused by stresses set up when the forging passes through a depressed crit. range. The remedy is a slow and controlled cooling rate. The temp. of the work should never be allowed to go below 700°F. until the grain is refined. W. A. Mudge

**Standardization of tempering of alloy steels.** V. D. Sadovskii and P. A. Trofimov. *Dokl. Akad. Nauk SSSR* 19, 19. A study was made of the process of decomposition of austenite in supercooled tool-steel analyzing C 0.65, W 16.27 and Cr 3.86. Conclusion. For high-speed tool steel temp. limits for tempering are 720–780° and for Ni-Cr steels, 600–660°. S. L. Madorsky

**Graphic solution of technical calculations in alloy melts** Alfred Koster. *Metall u. Erz* 30, 406 8(1933). An explanation is given of graphic methods applied to binary and ternary alloys. H. Stoertz

**Phenomena of quenching and tempering in alloys.** Albert Portevin. *J. Inst. Metals* 51, 315 56(1933); *Chim. Ind.* 27, 5701. Improvements in exptl. technic and app. have been effected in the past 20 years. In addn. to thermal analysis, dilatometric analysis, thermomagnetic analysis and x-ray spectroscopy are useful. In binary alloys almost all cases of quenching are connected with the following: (1) the increase of solv. in the solid soln.  $\alpha$  of a phase  $\beta$  which is frequently a chem. compd. or intermediate phase; (2) the transition on heating a mixt. of 2 phases  $\alpha + \beta$  into a single phase  $\gamma$ . Thermal treatment of the light alloys of Al represents case 1, while that of steels represents case 2. Quenching alloys of case 1 does not, in general, produce an important hardening with a marked increase in strength. This result is obtained by the pptn. of compd.  $\beta$  from the supersatd. soln. on the return to an equil. state, i. e., by a tempering effect. The laws of tempering are the expression of the speeds of reaction starting from a non-equil. system. Variation of hardness is also influenced by the phenomenon of coalescence which follows laws analogous to those of pptn. The phenomenon of quenching with structural hardening is common as shown by the following instances of hardening by pptn.: Al contg. Si, Be, Cu, Mg, Si, Ag and Zn; Ag contg. Cu, Cd, Cu Cd, Si, Cu Si, Cu Mg, Cu Sb, Mg Zn, Cu contg. Ag, Be, Cu, Co, Fe, Pd, Pt, Si, Be Si, Co Si, Cr Si, Mn Si, Ni Si, Ni P, Ti, Zn; Au contg. Cu, Fe, Ni, Ni Si, Co Si, Cu Si, Pd, Zn; for Fe (ferrite or austenite) contg. B, Be, C, Cu, Mn, Mo, Nb, O, Ta, Ti, U, W, Zr; Co and Ni contg. B, Be, Si, Ti; Pb contg. Bi, Ca, Sb, Sn; Pd and Pt contg. Au, Ag, Cu; Sn contg. Pb; Zn contg. Al, Cd, etc. Influence of the crit. values of quenching factors, time, speed, temp., etc., on the physicochem. states of sol are discussed. C. B. Jenni

**The uses of aluminum and its alloys.** A. V. Sibiley. *Centraire Metal* 1931, 1672 98; *Chem. Zentr.* 1932, II, 118. Discussion of tech. uses. M. G. Moore

**The heat treatment of aluminum-bronze components** P. Mahb. *Machinery* (London) 43, 39 42(1933). Al bronze responds to hardening treatments in a similar manner to steels; Al is the crit. element, instead of C as in the latter case. Details are given with photomicrograph of the effects of heat treatment and hardening, and of the presence of addnl. alloying elements. By heating the alloy contg. 10.3% Al to 520–40° and slowly cooling, the amts. of  $\alpha$ - and  $\beta$ -constituents are obtained; the  $\beta$ -constituent is distributed in a very uniform fashion, and with all the tendency toward the lamellar condition, throughout the soft matrix of  $\alpha$ . A. W. Furbank

**Critical study of the hardness behavior of duralumin.** Hugh O'Neill, J. F. B. Jackson and G. S. Parnham. *Phil. Mag.* 16, 913 29(1933). The changes in hardness with heat treatment were studied by the Meyer (ball-test)

analysis. Age hardening at room temp. is analogous to the strain-hardening of a slightly cold-worked metal. "Pptn." can be caused by a sufficiently long heat treatment above 200°. The lattice parameters were measured for a no. of samples. No easily measured change occurs during age hardening. The processes which might be operating in the hardening are discussed. F. J. Rosenbaum

**Metals in art.** Louis Delville. *Arts et Metiers* 8, 197 202, 231(1933). Sn, Ag and bronzes found extensive use in ornamental and artistic objects. Forged duralumin along with stainless steels are now used in modern furniture, while forged Fe and Cu are used in decorating portals. G. T. Motok

**High-grade chromium-nickel alloys and the testing of their life.** W. Hessenbruch and W. Rohn. *Elektrowärme* 3, 245 9, 291 7, 317 22(1933). Methods of production of Cr-Ni alloys for resisting high temps. are described. Phys. properties of various alloys, chem. resistance, influence of frequency of switching current on and off, and metallographic investigations are discussed. Almost all Fe-contg. Cr-Ni alloys when used at high temps. show in the course of use a segregation of a ternary compd. Fe-Cr-Ni while in the unmixed state the alloy consists of pure solid solns. of Ni-Cr-Fe-Mn-Si; this segregation takes place at the grain boundaries and also in the interior of the grain, and is the greater the higher the Cr content. M. Hartenheim

**Chromium-nickel as a corrosion-resistant alloy.** R. J. McKay. *Metals & Alloys* 4, 177 80(1933). Various uses are suggested and corrosion-resistance figures are given for the Ni alloy Inconel contg. 12 14% Cr and 5 6% Fe. Downs Schaaf

**Heat-resisting chromium-nickel-iron alloys for furnace construction.** L. J. Stanbery. *Metals & Alloys* 4, 127 35, 159 64(1933). Available load-carrying data for Cr-Ni-Fe alloys are assembled from various sources as an aid to the designer of parts subject to operating temps. of 650–1150°. Selection of alloy compn. and treatment are considered for the conditions under which they are used and also as to their suitability for fabrication and for casting. Downs Schaaf

**High-chromium iron alloys for castings.** W. F. Furman. *Metals & Alloys* 4, 147 50, 167 9(1933). Cr-Fe castings contg. 20% Cr with varying C and without other alloying elements are described and defined. The effects are noted of small addns. of Ni, Mo, W, Ti, Mn and N on straight Cr-Fe castings. Downs Schaaf

**Change of volume of iron alloys in the melting range.** F. Sauerwald and F. Fleischer. *Arch. Eisenhüttenw.* 7, 219 21(1933). Investigations on different Fe alloys of the effect of gases, occurrence of graphite, and of the eutectic have shown that the increase in the content of C of the  $\gamma$ -solid soln. which takes place during solidification is, for white cast iron and steel, connected with expansion and the decrease during melting with contraction. The dissolving of the graphite in the solid soln. and in the melt during heating causes a contraction in graphitic cast iron, the segregation during cooling an expansion. All these phenomena are superimposed on one another more or less in ordinary cast iron, and the vol. is further influenced by the gases of reaction. M. Hartenheim

**Fundamentals of alloying gray cast iron with metals.** Franz Roll. *Gießerei* 20, 401 6(1933). The influence of metal addns. on the stability of the carbide, the eutectic and eutectoid points, the graphite structure, strength, wear and corrosion are reviewed. C. L. Wilson

**Ferrosilicon.** H. Delomenie. *Compt. rend.* 197, 249 52(1933). Microscopic examn. of alloys contg. approx. 50% Si confirms the existence of FeSi. The crumbling of industrial alloys appears to be due to the presence of P and As. Also in *J. four elec.* 42, 278(1933). J. B. Austin

**Preparation of non-liquating lead-zinc alloys.** A. A. Bocharov and A. Ya. Ulyanov. *Izvestia Metal.* 1932, No. 5/6, 28 32. Alloys of Zn with 1% of Pb can be prep'd. by dissolving the required amt. of Pb in the liquid Zn at high temps. However, upon solidification the Pb seps. out, and liquation takes place. In order to prep. a

uniform alloy free from liquation the authors made 1.5% Pb alloys by introducing PbCl into molten Zn. Upon solidification the structure was found to be uniform and the micrographs obtained by etching with HCl showed uniform darkening, indicating the absence of segregation or liquation. The fact that the Pb content of the ingots exceeded the solubility limit indicated that Pb was present as an emulsion. On remelting part of the Pb came out. Further expts indicated that the liquation can be partly prevented by adding small amt of Mg and wholly by Cd, Fe and Cu. Fe t by dissolving thin rolled plate in a 40-50% soln of  $\text{NH}_4\text{NO}_3$  showed some traces of coagulation of Pb, although not sufficient to cause liquation. The existence of coagulation was interpreted as indicating the absence of a solid soln of Pb in Zn. B. N. Dandloff.

**The equilibrium diagram of iron-nitrogen alloys.** See Nishigori, *Tech. Rept. Univ. of Tokyo*, No. 11, No. 1, 68-92 (1933). Samples were prepared by passing  $\text{NH}_3$  gas over thin down electrolytic Fe wire at various temps., and were annealed for 40 days at 600 mm Hg. The change of electrical resistance on heating and cooling were measured and x-ray, magnetic and metallographic studies of alloy were made. Two eutectoid transformation were found on heating: (1) 0.8% and (2) 0.6% corresponding to the eutectic  $\alpha + \gamma$  and  $\gamma + \delta$  respectively. The Fe t and large drop in resistance above 600°C thought to be due to the rapid decomposition of nitride. The remaining nitride continues to decompose gradually until 900°C is reached. It is maintained that only 2 nitrides exist: Fe<sub>3</sub>N and Fe<sub>4</sub>N, and that no Fe-N compound Fe<sub>2</sub>N can exist in the system. The diagram proposed by Lecher is recommended (C. I. 24, 427-192). H. W. Lurhbeck.

**The system iron-nickel-aluminum.** W. Koester, *Arch. Eisenhüttenw.* 7, 51-62 (1933). The partial diagram of the system Fe-Ni-Al was determined up to 0% Al. Ni-Al form an uninterrupted series of solid solns with  $\alpha$  Fe  $\beta$  that only  $\alpha$  and  $\gamma$  solid solns occur in solid phase in the investigated range. The peritectic equl.  $\delta + \alpha = \gamma$  in the Fe-Ni system changes gradually into the eutectic equl.  $\delta + \alpha + \gamma$  in the system Fe-Al by passing through a minimum temp. The temp. of the magnetic transformation point of Fe-Al alloys increases at first with increasing Ni content. The  $\alpha$  solid soln of Fe-Ni alloy is in general reversible at 20°C Al and 0% Ni. The Curie point for higher Al and Ni content lies after quenching from higher temps. considerably lower than after heating to medium temps. The miscibility gap in the system are discussed. M. Hartenbaum.

**The system iron-cobalt-aluminum.** W. Koester, *Arch. Eisenhüttenw.* 7, 263-4 (1933) (cf. preceding paper). The partial equilibrium diagram up to 0% Al of the system Fe-Co-Al differs from that of Fe-Ni-Al only quantitatively, this is illustrated by a dimensional diagram. The eutectic line is at 1.70 between 8.5 and 1.0% Al; the eutectic contains about 11% Al. The magnetic transformation of Fe-Co-Al alloy is in general reversible at the border of the ferromagnetic field heat treatment exert a similar influence as in Ni alloys. Miscibility gap and transformation point under varying conditions are discussed. M. Hartenbaum.

**Ternary alloys of thallium with lead, cadmium and tin.** N. S. Kurnakov and N. I. Korotkiy, *Izv. Akad. Nauk SSSR, Khim. (Comm. d.)* 6, 4 (1933). The ternary systems Pb-11-Cd and Pb-11-Sn were studied thermally. It was found that the addition of Cd or Sn to the binary system Pb-11 disturbs the equl. of the latter and changes the ratio Pb-11 = 1 (16.18%) corresponding to the max. fusion temp. This is similar to the liquid-vapor type of binary system, where equl. disturbance due to change of temp. and pressure results in a change of vapor pressure. Eutectic lines in the above ternary system deviate considerably from a straight line connecting eutectic points of the corresponding binary systems. Addition of 1% Cd or 5% Sn to the system Pb-11 slightly changes the character of the system. S. I. Medvedev.

**Mechanism of inverse segregation.** Alloy group 3 Sn

bronzes, 89-11 type (Open W. Ellis, *Metal Ind.* (London) 43, 194-6 (1933)). The Cu-Sn alloy of the 89-11 type remains molten at temp. well below the solidus of the alloy when poured into molds of the dimensions used in foundry practice; it cools at such rate that primary crystals are delayed until the metal in the mold has reached a temp. at least a few degrees below a point half way between the equilibrium liquidus and solidus. If crystals are delayed until a temp. of 910°C has been reached, the crystal nuclei will contain approx. 7% Sn. Upon these nuclei dendrites will form. If nuclei appear in the melt within the body of the casting at 900°C the Sn content would be about 5%. The dendrites that form around these nuclei on cooling from 900°C to 800°C contain approx. 9% Sn and the melt contains about 50% Sn. The slower the rate of growth of the dendrites the richer in Sn they will be. Other factors exert themselves in inverse segregation, which tends to raise the Sn content of the outer part of the casting. The interdendritic flow theory suggests that cavities are formed around growing crystals because of contraction, and that molten alloy richer in Sn is forced into contact with the crystals and solidifies. *Ibid.* 22, 6. The casting possessing the best mechanical properties was poured at 1100°C and had a yield of 8.18. When the metal (88-10.2%) is poured too hot the metal actually rises in the mold because of formation of blowholes. When poured too cold the surface cracks. Between these extremes sound castings are obtained. Brinell hardness was taken at the centers of but increased uniformly as the pouring temps. were decreased. Large castings are less dense at their interiors than at their surface. Casting poured at high temp. cool more slowly and give larger crystals and form a strong interlocking structure. Annealing at 700°C decreased the porosity of the metal by surface oxidation. The ideal microscopic structure obtained from a high pouring temp. contains large and connected areas of eutectoid. The capillaries formed by the crystals of the dendrites are filled with Sn-rich liquid from the center of the casting. *Ibid.* 33, 4. An alloy which when cast under specified conditions gives evidence of inverse segregation subsequent to solidification may upon the addition of small quantities of Fe, Mn or Zn become normal in its behavior under the same condition of casting. The added element may change the temp. of primary solidification and modify the size of the dendrites, may alter the diffusibility, may change the surface tension or may alter the vapor pressure of the Sn-rich liquid. Referring to a Cu-7% Al alloy, rapid cooling increases inverse segregation in the absence of gas, but when gases are present the effect of rapid cooling may or may not cause an increase in the segregation of the Cu. H. I. Messmer.

**Artificial bronzing.** Eugen Werber, *Metallwaren Ind. u. Calim. Tech.* 31, 42-4 (1933). Chemical methods of coloring brass, Cu and Fe are given. C. I. Wilson.

**Theory of corrosion.** II. New expts. pertaining to the rusting of Fe based upon the film theory of passivity. W. J. Miller and W. Michu, *Amer. Inst. Metallurg.* 9, 197-204 (1933) (C. I. 27, 5294). The porosity of film on Fe electrodes in solns of  $\text{Na}_2\text{SO}_4$  and  $\text{NaOH}$  were computed. The area of the pores was found to vary within wide limits. Fe specimen is stored in air or provided with interference colors by moderate heating to 100-110°C. It was found that the electrical resistance across the pores is little influenced by the period of storage, but is greatly increased by heating. The same applies to the resistance of the film itself. The natural oxide layer is of a hydrous nature, 10<sup>-3</sup> cm thick, not influenced by long storage in dry air and its pores have an area of 2.10<sup>3</sup> to 5.10<sup>3</sup> sq cm per sq cm. The area of the pores increases with the period of immersion in  $\text{Na}_2\text{SO}_4$ , which phenomenon is obviously identical with the break down of the layer. After longer storage the original oxide layer has almost completely disappeared, although the electrode is covered with a black to brown rust layer, which change depends greatly on the original condition of the surface. It is concluded that the film does not break down mechanically but is removed by chemical or colloidal action. The different

corrosion rates on shielded and freely suspended electrodes are explained by the shielding action of accumulated Fe-salt soln. which prevents access of  $O_2$  and passivity.

Leopold Pessel

**Corrosion of metals under the influence of some gasolines and kerosenes.** N. I. Laduzhnikova. *Repts. Gost. Petroleum Research Inst. (Moscow) 1932*, 139-43. — Strips of various metals were immersed in gasoline from Ural contg. 0.458% S. It reacted considerably with Pb and to a smaller degree with Cu, brass and Fe, while its distillate did not attack brass or iron. A kerosene of the same origin which had 1.684% S attacked all 3 metals to a much greater extent, while the distillate which contained 1.925% S attacked Cu and brass more vigorously and Fe much less than the refined product. Cracked gasoline from Baku attacked, after contacting for 7 months, the following metals arranged in decreasing order of attack: Pb, Fe, Cu and brass. The attack was not so severe if the samples were kept in the dark. This phenomenon is explained by the presence of unsatd. compounds in the cracked gasoline which are oxidized in the presence of metals, the latter acting as catalysts. This gasoline also showed a higher acidity after the expt. Baku kerosene had a corrosive action on the following metals arranged in decreasing order: Pb, brass, Cu, Fe and Al, the latter was not attacked during the 21 months of the expts. This phenomenon was accompanied by an increase in the I no., the aniline pt. and the acidity. Kerosene satd. with water attacked the metals in a more severe manner than dry kerosene.

A. A. Bochtimgk

**Corrosion effects of lubricants on bearing surfaces.** Christopher H. Bierbaum. *Iron Age 132*, No. 9, 20-1, 58 (1933). Chem. effects of different lubricants are discussed. Practically all cause corrosion of the bearing, which may be beneficial if very slight and selectively directed toward the softer constituents. Other forms are unfavorable and destructive.

Leopold Pessel

**Corrosion of electric bulb bases.** Otto Herbatschek. *Korrosion Metallschut. 9*, 209-12 (1933). Discussion of the corrosion phenomena caused by a store room fire. Reconditioning of the bases thus damaged is of uncertain value.

Leopold Pessel

**Prevention of corrosion of the grain-boundaries in steels with 18% chromium and 8% nickel.** F. Houdremont and P. Schalmesser. *Arch. Eisenhüttenw. 7*, 187-91 (1933). Corrosion of the grain-boundaries occurs in austenitic, non-rusting steels with 18% Cr and 8% Ni if Cr-rich carbides are sep'd in finely distributed form during tempering to about 500-800°, and the surroundings of the grain boundaries thus become lower in Cr. By reducing the C content to a max. of 0.07%, segregation of carbide and disintegration of the grain boundaries can be avoided. Also, the addn. of carbide producers will reduce the soly. of carbide in austenite to such extent that intercryst. corrosion is prevented, addn. of Ti is particularly suitable. It is possible to agglomerate the carbides by annealing, especially after cold working, and to make them segregate in the austenite grains so that the grain-boundaries remain free from carbide films at subsequent tempering. A mixed structure of austenite and ferrite proved to be particularly resistant to corrosion. If Ti is added the yield reduction of elongation and reduction of area at 700-800° accompanying grain-boundary corrosion and segregation of carbide is hardly noticeable. Seven references.

M. Hartenheim

**Explanation of mechanism of corrosion fatigue and its application to sucker-rod failures.** Blaine B. Wescott and Norman Power. *Oil Gas J. 32*, No. 23, 65, 68, 70, 72 (1933). The electrochem. nature of corrosion generally results in the formation of pits which leads to marked trans. When this reaches a value greater than the endurance limit, cracks form at the base of the pits. These cracks are propagated by stress concn. until failure occurs.

**Effect of organic coatings in preventing damage of metal subjected to stress and corrosion.** F. N. Speller and

J. B. McCorkle. *Oil Gas J. 32*, No. 23, 73, 74 (1933). J. R. Strong

**Electromagnetic thickness tester for corrosion-resisting coverings.** E. Schweiter and S. Kiesshult. *Herbstkolloid Korrosion 8*, 33-4 (1933). A method for detg. thickness of non-magnetic coverings for steel or iron. An electromagnetic field is brought up to the coating by means of an electromagnet. The current required is measured, and from a calibration chart the coating thickness can be detd.

M. C. Rogers

**Effects of absorption of oxygen and nitrogen in fusion welding.** Eugen Piwowarsky and W. Klemm. *Arch. Eisenhüttenw. 7*, 205-8 (1933). Tests with unalloyed wires of 0.02-0.1% C and Ni-alloyed wires of 0.05-0.15% C and 2-3.5% Ni showed that a weld made with bare wire absorbs the greatest amts. of N and O; welds made by autogenous welding methods absorb even less than those made with covered electrodes, a. c. favors the absorption more than d. c.; Ni and Mn retard it. Tensile strength, elastic limit and hardness increase, and elongation, reduction in area and notch toughness decrease if by annealing above A<sub>1</sub> and slow cooling or by tempering at 600°, cold-working and tempering at 250° or by natural aging the excess amts. of N, O and C can be expelled. Ni-alloyed autogenous welds and elec. welds made with covered Ni-alloyed electrodes behaved best against aging for a certain content of N and O.

**Reciprocating pumps for liquids for the treatment of mineral ores.** The General Electric Co. Ltd., Herbert W. B. Gardiner and Alexander B. Jackson. Brit. 396,460, Aug. 10, 1933.

**Treatment of iron and manganese ores.** Vereinigte Stahlwerke A.-G. Ger. 586,078, Oct. 18, 1933. Fe and Mn ores are freed from As and Sb by treatment at a raised temp., preferably above 500°, with a mixt. of  $CO_2$  and a

reducing gas, *e. g.*, H, CO or a hydrocarbon. The compn. of the gas mixt. must be such that production of metallic Fe or Mn or their carbides is avoided. A suitable mixt. contains  $\text{CO}_2$  50-70 and CO 50-30%, or  $\text{CO}_2$  70-90 and H 30-10%. The  $\text{CO}_2$  content of the gases may be raised toward the end of the process.

**Treating manganese ore.** Napoleon A. Laury (to Howard B. Bishop). U. S. 1,932,413, Oct. 31. Material such as hot ore from a reducing furnace is leached with a soln. of an  $\text{NH}_4$  salt such as  $(\text{NH}_4)_2\text{SO}_4$  which is capable of forming a sol. manganous salt;  $\text{NH}_4$  is simultaneously removed from the leaching liquid, and the  $\text{NH}_4$  is then used to ppt. a Mn compd. from the soln. obtained.

**Treating sulfide ores.** Charles R. Kuzell. Brit. 396,600, July 31, 1933. Complex sulfide ore contg. Fe is subjected to an intensive oxidation, thereby removing most of the S and forming a molten product in which most of the Fe is present as magnetite. Ores deficient in fuel value are first coned, or mixed with ore of higher sulfide content. Extraneous fuel may also be used. The molten product is subjected to a selective reduction by a gas or atomized agent blown through the melt or by a solid reducing agent mixed with the melt by means of a gas blown therethrough. A tilting furnace or barrel converter for carrying out the oxidation and reduction is described. Fluxes, *e. g.*,  $\text{CaO}$ ,  $\text{CaF}_2$ , that are required in subsequent operations are charged with the ore. S, Pb, Zn, Cd, etc., pass off in the oxidation process. The reduction produces gases contg. a further part of the volatile constituents, a  $\text{FeO}$  slag and a product such as impure Cu or Cu matte which seps. by gravity from the  $\text{FeO}$  slag. The Cu-contg. product is treated in a converter to produce Cu contg. Au and Ag, any Fe present being slagged off and returned to the initial melt of ore. The Fe product of the selective reduction is reduced in a fuel or electrically heated furnace by treatment similar to the first reduction by means of, *e. g.*, natural gas. The Ca aluminosilicate slag formed is worked up into portland cement.

**Roasting plumbiferous sulfide ores.** Kenneth W. Young and Imperial Chemical Industries Ltd. Brit. 395,760, July 24, 1933. PbS is recovered from sulfide ores contg. small amts. of Pb, *e. g.*, pyrites, by roasting with a limited supply of air or O-contg. gas in a rotary, shaft kiln or mech. furnace so that the O is entirely used up and a portion of the heated material in contact with gas free from O. An O-free gas, *e. g.*, N and (or)  $\text{SO}_2$ , is introduced into the furnace in sufficient quantity and at such velocity, *e. g.*, 20 cm. per sec., to volatilize and remove the PbS. The exit gases are cooled, *e. g.*, to  $100^\circ$ , and the PbS ppt., *e. g.*, by an electrostatic precipitator. The charge may be mixed with coke, etc., whereby S is evolved, being condensed after removal of the PbS. The gases so obtained are, after removal of excess N, preferably used as the O-free gas, being introduced wholly or in part into the combustion zone or with the O-contg. gases as described in Brit. 359,478 (C. A. 26, 4923) to control the temp. of the combustion zone to about  $800-900^\circ$ . Cf. C. A. 28, 87.

**Eliminating arsenic and antimony from iron and manganese ores.** Vereinigte Stahlwerke A.-G. Brit. 396,058, July 26, 1933. See U. S. 1,923,511 (C. A. 27, 5045).

**Reducing oxide ores such as those of iron, chromium, etc.** Donald M. Scott (to Buffalo Electric Furnace Corp.). U. S. 1,932,831, Oct. 31. A coherent and adherent charge is formed of comminuted ore, reducing agent such as pitch or Si and flux such as lime and sand, and the charge is progressively fed through a hollow electrode of an elec. arc furnace and toward the arc end of the electrodes (which is enclosed within an inner wall inside the furnace chamber and out of contact with the electrodes, serving as a muffle). Various details of app. and operation are described.

**Reduction of iron ore.** Karl H. Moll, Harold Etherington and David F. Smith (to A. O. Smith Corp.). U. S. 1,934,082, Nov. 7. In the reduction of a charge comprising a mixt. of Fe ore and flux in a vertically disposed shaft the charge is smelted in the lower portion of the shaft by

the combustion of gas and preheated air, and in the upper portion of the shaft the charge is reduced by contact with a reducing gas and with heated gases ascending from the lower portion of the furnace. Reducing gases are added for locally cooling the ascending gases immediately above the point of fusion, and the charge is drained from the base of the shaft as rapidly as it is smelted. App. is described.

**Recovery of metals from ores, etc., by use of mercury.** Fredus A. Thurston. U. S. 1,933,193, Oct. 31. In treating materials such as ores or the like with Hg, a cleansing agent such as  $\text{NH}_4\text{F}$  or  $\text{HOAc}$  is also used and the mercurized mass is heated, broken up after cooling, further treated with cleansing fluid, dried and pulverized.

**Apparatus for extracting gold from solutions such as sea water by adsorption with ferrous sulfide.** Herschel C. Parker. U. S. 1,932,531, Oct. 31. Various structural, mech. and operative details are described.

**Extracting tin from ores.** Louis A. Wood and Henry L. Sulman. U. S. 1,931,944, Oct. 24. The ore is mixed with carbonaceous material such as crushed coal and with  $\text{CaCl}_2$  soln. which serves as a chloridizing agent and also as a binder, and the mixt. is heated to effect distn. of the Sn in the form of chloride. App. is described.

**Recovery of metallic values from slag.** Edward P. Fleming and Armand L. Labbe (to American Smelting & Refining Co.). U. S. 1,932,656, Oct. 31. A bath of molten slag such as that contg. Pb, Zn and Ag is heated directly with an air-gaseous fuel mixt. contg. an excess of air, to maintain the slag in molten condition and in contact with an oxidizing atm., and is agitated to liberate metals in the form of oxides which are recovered. App. is described.

**Metallurgical furnaces.** Heraeus Vacuumschmelze A.-G. and Wilhelm Rohm. Ger. 577,657, June 2, 1933. The protective covers of the above furnaces are filled with a gas lighter than air and forming an explosive mixture therewith, *e. g.*, H, before the oven is operated and emptied after the operation is finished, the filling and emptying taking place at a distance from the furnace.

**Furnaces for roasting ores.** La Nouvelle Montagne. Fr. 41,751, Apr. 13, 1933. Addn. to 726,339 (C. A. 26, 4923). In roasting ores contg. powd. blends, all parts of the combustion chamber of the furnace are maintained at a temp. above that of the decompn. of  $\text{ZnSO}_4$ , and the roasted material is removed from the action of the roasting gases before being cooled below that decompn. temp.

**Shaft furnace construction and operation for reducing ores such as those of iron.** Karl H. Moll, Harold Etherington and David F. Smith (to A. O. Smith Corp.). U. S. 1,934,081, Nov. 7. A mixt. of air and gas is burned in the lower portion of a vertically disposed ore-reduction shaft, and a reducing gas is admitted into the shaft at a point above the point of fusion of the charge. Reduced and molten material is withdrawn from the lower portion of the shaft as formed.

**Stirrer for superimposed-hearth furnace for roasting ores, etc.** Humboldt-Deutzmotoren A.-G. Ger. 586,192, Oct. 17, 1933.

**Metal-melting furnaces.** Stephen Stanworth, James H. Clegg and James Stanworth. Brit. 395,766, July 27, 1933.

**Carbon- or graphite-tube furnace for melting carbides.** Fried. Krupp A.-G. Ger. 576,263, May 17, 1933. Addn. to 516,656 (C. A. 25, 2679).

**Reversible regenerative rocking furnace for melting metals.** Arthur E. Vogt and Ludwig Kirchhof. Brit. 395,143, July 13, 1933.

**Regenerator suitable for use with blast furnaces.** Albert J. Hulse (to H. A. Brassert & Co.). U. S. 1,933,114, Oct. 31.

**Pressure control in furnace combustion chambers.** George W. Smith (to John M. Hopwood). U. S. 1,931,906, Oct. 24. Various structural and operative details are described, suitable for control of furnaces such as those for metallurgical purposes.

**Muffle furnaces.** Willoughby S. Smith, Henry J.

Garnett and Walter F. Randall. Brit. 395,371, July 13, 1933. In the manuf. of sheet, wire or strip from ingots of Ni (alloys) the ingots are raised to the temp. necessary for working in a combustion-heated muffle furnace in which the muffle is formed of fireclay with an internal lining of Cr-Ni alloy.

**Vertical conveyer oven suitable for foundry cores.** Charles A. Barnett and Harry W. Steindorf (to Foundry Equipment Co.). U. S. 1,934,904, Nov. 14. Structural and mech. features.

**Apparatus for heating metal slabs and rolling them into sheets.** Florence C. Biggert, Jr. (to United Engineering & Foundry Co.). U. S. 1,932,504, Oct. 31. Mech. features.

**Transportable container for molten materials, e. g., metal, slag, which may serve also as a ladle or mixer.** John D. Pugh. Brit. 396,221, Aug. 3, 1933.

**Sampling liquid metals.** Charles B. Francis and Paul B. Guyer. U. S. 1,933,425, Oct. 31. A device is described which is immersed in molten metal such as an alloy steel to obtain a sample which is chilled on the device and then stripped off.

**Apparatus for spraying molten metals such as lead, tin or zinc.** Donald D. Taylor (to Advance Engineering Corp.). U. S. 1,934,891, Nov. 14. Various structural, mech. and operative details are described.

**Mold materials.** John A. Gann (to The Dow Chemical Co.). Brit. 396,645, Aug. 10, 1933. Mg (alloys) or other readily oxidizable metals are cast in molds having hydrofluoboric acid or a volatilizable salt thereof incorporated in the molding compn.; 1-3% of the acid or 0.5-10% of the  $\text{NH}_4$  salt may be used, with or without other protective agents, e. g.,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{NH}_4\text{F}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NH}_4\text{Br}$ ,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{NH}_4\text{HSO}_4$ ,  $\text{S}$ ,  $\text{H}_2\text{BO}_3$ .

**Ingot mold.** Charles W. Meyers and Walter F. Munford. U. S. 1,933,530, Oct. 31. Structural features are described of an ingot mold having an induction coil for heating the upper portion.

**Molds suitable for iron-foundry use.** Harry P. Kumber (to Erb-Joyce Foundry Co.). U. S. 1,935,362, Nov. 14. Permanent molds are formed of chrome ore 3, fused silica 1 and bentonite 1 part.

**Sand molds for casting magnesium, etc.** Maurice N. Lacey (to British Maxium, Ltd.). U. S. 1,935,591, Nov. 14.  $\text{NH}_4$  fluoride or borate (suitably in a proportion of about 2% or less) is mixed with the sand contacting with Mg or other like easily oxidizable metals.

**Apparatus for pressure die casting of metals such as magnesium.** John E. Hov (to Dow Chemical Co.). U. S. 1,932,823, Oct. 31. Various structural and operative details are described.

**Cast metal stair treads, etc.** Donald S. Connelly and Theodore J. Hahn (to Wooster Products Inc.). U. S. 1,934,592, Nov. 7. Cast metal articles such as stair treads are formed with spaced stratifications of wear-resisting material such as steel plates carrying carborundum embedded in them. Cf. C. A. 27, 4761.

**Making hollow articles such as balls or shells from cast metal such as brass or bronze.** Arthur A. Schupp (to Fredericksen Co.). U. S. 1,934,239, Nov. 7. Various details of app., operation and temp. control are described.

**Metal compositions.** Floyd C. Kelley (to The British Thomson-Houston Co. Ltd.). Brit. 396,120, Aug. 3, 1933. A sintered hard metal compn. consists of Cb carbide, Ta carbide in excess of the Cb carbide and a metal cementing material consisting of metal(s) of the Fe group and W and (or) Mo, the carbides forming the major portion of the compn. Powd. Ta and Cb carbides are ground with a mixt. of, e. g., Fe and Mo, and the mixt. is hydraulically pressed to the desired shape and fired in a closed graphite tube in a H furnace at 1400-1600° or, after pressing, the mixt. may be fired at 800-1100°, shaped or cut to the desired size and then fired at 1400-1600°. For use as a tool bit the cemented carbides may be Cu brazed to a steel shank. Cf. C. A. 27, 5299.

**Metallic compositions.** N. V. Molybdenum Co. and Paul Schwartzkopf. Brit. 395,745, July 17, 1933. In

compus. consisting of 1 or more hard metals, e. g., W, Mo, Ta, bonded by 1 or more soft metals, e. g., Ag, Au, Al, Cu, Pt, Sn, Zn, the hard metal in the powd. form in which it is obtained from its compds. or ores is sintered or melted and, if desired, hammered, rolled or otherwise mechanically worked and then finely powd. before bonding with the soft metal. The composite material may be heated and chilled or otherwise treated to obtain a fine cryst. structure. Articles may be made having different proportions of hard metal in different parts. Other metals, e. g., Ti, V, Zr, Co, Cr, Ni, Fe, may be incorporated in the above compus.

**Metallic compositions.** Chrysler Corp. Brit. 396,195, Aug. 3, 1933. Porous flexible elements for insertion between the leaves of a laminated spring are made by mixing Cu 10, sponge Fe 88.5 and graphite 1.5 parts, together with a small amt. of volatile lubricant, e. g., petroleum, stearic acid, compressing under high pressure, sintering at about 2100°F. in a non-oxidizing or reducing atm. and then quenching with oil before cooling or immersing in oil after cooling. The porous elements may also be similarly made from a mixt. of powd. Cu 85, powd. Sn 13 and graphite 2 parts, with a small amt. of stearic acid.

**Metallic powder.** Soc. anon. Le Carbone. Brit. 396,250, Aug. 3, 1933. Contact pieces for elec. switches, etc., and carbon brushes are made of C with which is incorporated a powd. base metal coated with an unoxidizable metal, e. g., Cu coated with Ag. A suitable powder may be made by dropping powd. Cu through a 300-mesh sieve into a  $\text{AgNO}_3$  soln. contg. 2.5 g. Ag per l.

**Metallic powders such as disintegrated bronze foils.** Erwin Kramer (to Hartstoff-Metall A.-G.). U. S. 1,932,711, Oct. 31. In effecting disintegration by the action of balls in a rotary drum, the proper proportions of metallic particles and balls to obtain high efficiency in output of the powder is detd. by placing a quantity of the balls in the drum, supplying metallic particles to the drum until the output of the powder rises to a distinct max., and then supplying more balls until the output of the powder falls to a min. and subsequently rises to a second max. higher than the first max.

**Apparatus for briquetting metal shavings.** Waldemar Lindemann. Ger. 586,325, Oct. 20, 1933.

**Smelting solid substances with high melting point.** Mathias Frankl (to Société oxythermique). Brit. 396,698, Aug. 3, 1933. In a shaft furnace for the production of Si-Fe or carbides, the reduction of ores or the melting of steel scrap the charge is agglomerated or sintered in the upper part of the shaft so that it will form a self-sustaining column spaced from the enlarged lower part where the melting is effected.

**Separating metals such as nickel and copper by selective oxidation of their chlorides.** Raymond G. Brown (to Sulphur & Smelting Corp.). U. S. 1,933,702, Nov. 7. A mixt. of oxidizable anhyd. metallic chlorides such as chlorides of Ni and Cu or Co is treated with an oxidizing gas such as air at a temp. promoting oxidation, and sufficient Cl is introduced into the reaction zone to inhibit oxidation of at least one of the chlorides of lesser reactivity with O, while oxidizing other chlorides present.

**Treating lead to remove oxidizable and chloridizable constituents such as zinc.** Jesse O. Betterton and Yuri E. Lebedeff (to American Smelting & Refining Co.). U. S. 1,934,480, Nov. 7. Portions are continuously withdrawn from a bath of the material, subdivided into parts which are treated with a chloridizing agent such as Cl and with an oxidizing agent such as air, resp., by which material such as Zn is removed as chloride and oxide; unreacted Pb and products of reaction are returned to the bath and the oxide and chloride are caused to form an oxychloride slag which seps. and is removed from the surface of the metal. App. is described.

**Apparatus for treating metals as in the removal of zinc from lead.** Jesse O. Betterton and Yuri E. Lebedeff (to American Smelting & Refining Co.). U. S. 1,934,479, Nov. 7. Structural and mech. features.

**Treating metal before working.** Nikolaus Bregger (to Anton Knip, Fritz Krassl, Hugo Roth, Rudolf Knips and Herbert Schallenberg-Krassl (trading as C. T. Petzold & Co.)). Brit. 396,284, Aug. 3, 1933. Addn. to 367,738 (C. A. 27, 2924). Metal work pieces, *e. g.*, tubes, are prepd. for drawing as described in 367,738 and then coated with a fatty substance, *e. g.*, by immersion in a bath contg. talc, French chalk, soapstone, graphite, PbO, etc., with oil and turpentine.

**Chilling metals.** Pomosm-Werke G. m. b. H. (Robert Feix, inventor). Ger. 577,711, June 3, 1933. Pectin substances are used as chilling agents for hardening steel and similar metal alloys.

**Carbonizing metallic articles.** Fredolf J. Peterson. U. S. 1,934,614, Nov. 7. Various details of app. and operation are described.

**Carburizing metals.** Roysel J. Cowan (to Surface Combustion Corp.). U. S. 1,932,032, Oct. 24. Metal to be carburized, such as steel, is passed, in the same direction as a carburizing gas, through successive heat zones of a single chamber, the first zone of which is maintained at a lower temp. than the succeeding zone and formed of material such as "calorized" iron or steel which is less active as a catalyst than steel in assisting in the thermal decompn. of a hydrocarbon gas with liberation of soot, the succeeding zone being maintained at carburizing temp.

**Pickling and cleaning metals.** Robinson Brothers Ltd., Derie W. Parkes and Charles D. Mitchell. Brit. 396,053, July 20, 1933. A substance for use as a restrainer in pickling Fe or steel or as an ingredient for cleaning them prior to painting is prepd. by heating with S or S chloride a mix consisting mainly of homologs of pyridine and quinoline, separately or mixed in any proportions, but which may also contain other cyclic nitrogenous bases, *e. g.*, piperidine bases or the dipiperidyls. A preferred mix is that commercially known as heavy pyridine bases. In an example the product is mixed with H<sub>2</sub>SO<sub>4</sub>, impurities that sep. are removed and the liquid then blown with steam. Casein, glue, size, sulfite cellulose lye, etc., may be added to produce a frothing restrainer which decreases acid spray and facilitates subsequent removal of dirt from the metal.

**Pickling iron and steel.** George L. Magoun (to Rubber Service Laboratories Co.). U. S. 1,932,553, Oct. 31. A soln. of H<sub>2</sub>SO<sub>4</sub> is used with a small proportion of an inhibitor comprising a reaction product of a fully satd. aliphatic amine and a mercaptobenzothiazole such as the reaction product of (CH<sub>3</sub>)<sub>3</sub>NH<sub>2</sub> with 2 mercaptobenzothiazole. Cl. C. A. 27, 1307.

**Metal pickling baths.** James H. Gravell. U. S. 1,932,015, Oct. 24. The action of baths such as dil. acid used for pickling metal is controlled by use of a briquet of a d. to sink in the bath and which is composed of comminuted solid inhibiting material such as di-*o*-tolylthiourea and a "blasting agent" comprising an alk. substance such as Na<sub>2</sub>CO<sub>3</sub> for reacting with the bath soln. to produce a gas for disintegrating and dispersing the material of the briquet. Cl. C. A. 27, 5018.

**Apparatus for treating wire rod in pickling, and sulling and lime dipping chambers.** James S. Pfifer (to American Steel and Wire Co. of New Jersey). U. S. 1,933,533, Oct. 31. Structural and mech. features.

**Apparatus for conveying metal sheets, etc., through acid baths, furnaces, etc.** Hubert S. Thomas and Wm. R. Davies. Ger. 584,410, Sept. 19, 1933. This corresponds to Brit. 360,457 (C. A. 27, 455).

**Apparatus for annealing coiled wire or rod.** Carl J. Toll (to American Steel and Wire Co. of New Jersey). U. S. 1,933,461, Oct. 31. Structural features.

**Box-annealing ferrous sheets and plates.** Rufus E. Zimmerman (to American Sheet and Tin Plate Co.). U. S. 1,933,519, Oct. 31. Sticking of the metal sheets in box-annealing is prevented by treating the rolled and pickled sheets or plates by immersion in an aq. soln. contg. ZnSO<sub>4</sub> 0.001-0.2% previous to piling and annealing the material.

**Tempering.** Joseph H. Southern. Brit. 395,960,

July 27, 1933. Rolled steel rod, especially for springs, is quickly cooled in turbulent water. App. is described.

**Aluminum.** I. G. Farbenind. A.-G. (Johannes Brode, Carl Wurster and Erich Buttgenbach, inventors). Ger. 582,508, Aug. 17, 1933. Addn. to 581,310 (C. A. 27, 5010). See U. S. 1,854,684 (C. A. 26, 3193).

**Aluminum.** Aluminium Ltd. Fr. 749,608, July 27, 1933. The hardness of the surface of Al or Al alloys is increased by causing a diffusion of Mg into the surface. The surface is covered with finely divided Mg and heated to above 250°. Fr. 749,609, Al-Mg alloys contg. 5-16% Mg have higher resistance to corrosion if the Fe impurity is kept below 0.1% and below the amt. of Si.

**Working aluminum and maintaining its ductility.** Wm. T. Ennor (to Aluminum Co. of America). U. S. 1,931,913, Oct. 24. In operations such as wire drawing, the metal is continuously worked at a temp. below the temp. at which substantial metal recrystn. takes place, to a cross section greater than that finally desired, a substantial portion of the heat induced in the metal by the working is removed, and the metal is then worked to desired cross section. App. is described.

**Working aluminum to form rods, bars, wire or the like.** Raymond T. Whitel (to Aluminum Co. of America). U. S. 1,931,912, Oct. 24. The metal is progressively hot-worked and is rapidly progressively cooled from its hot-working temp. to a temp. not higher than about 100° to give it a substantially uniform internal structure throughout its length. App. is described.

**Extracting cobalt.** I. G. Farbenind. A.-G. Brit. 396,717, Aug. 8, 1933. Co nitrosocarbonyl (I) and (or) Co nitrosyl are obtained by acting with NO, if necessary together with CO, upon Co, or a material contg. Co as metal or in a state from which it can be reduced to metal by the reducing gases present such as excess CO. When I is produced, the NO may be wholly or in part replaced by substances supplying it, *e. g.*, nitrates. Substances, *e. g.*, Cu, that facilitate the production of the nitroso compds. may be added. The nitroso compds. may be burnt, or thermally decompd. in the presence of inert gases, to form CoO, thermally decompd. in the presence of reducing gases, *e. g.*, H<sub>2</sub>, to form Co or treated with strong mineral acids to form Co salts. Among examples an industrial waste contg. CaSO<sub>4</sub> and oxides of Fe, Cu and Co is dried, reduced by H<sub>2</sub> at 380° and treated with CO contg. 5% NO at 160-180° to produce I.

**Distillation retort for zinc.** The New Jersey Zinc Co. Ger. 577,891, June 6, 1933.

**Heat-treating white iron castings.** Anson Hayes, Edward E. Walker and Joseph J. White (to Industrial Furnace Corp.). U. S. 1,932,664, Oct. 31. In order to obtain a product of high tensile strength and some ductility, the iron is subjected to a temp. above the crit. temp. for a sufficient time to decompose substantially all of the massive cementite, then quickly cooled to a temp. below the crit. range to prevent further decompn. of cementite, reheated to a temp. in or just above the crit. range for a sufficient time to effect structural rearrangements and restricted chem. decompn. of the pearlitic cementite, and the heat treatment is terminated while the combined C content of the iron is greater than 0.45%. Cl. C. A. 27, 4206.

**Heat-treating malleableized cast iron.** Carl F. Lauenstein (to Link-Belt Co.). U. S. 1,934,313, Nov. 7. In order to improve its strength, malleableized cast iron is heated initially to just slightly below the effective practical C-combining temp. and is held at that temp. for a time sufficient to attain uniformity, then raised to a temp. definitely above the effective practical C-combining temp., then quenched and reheated to a temp. below the C-combining temp.

**Apparatus for making wrought iron.** Fredrik H. Wille (to A. M. Byers Co.). U. S. 1,933,577, Nov. 7. Structural and mech. features.

**Hardening iron and steel.** Maschinenfabrik Augsburg-Nürnberg A.-G. Ger. 586,450, Oct. 21, 1933. Iron and steel are carburized by cementation, then superficially

decarburized in known manner, and the decarburized portion is finally nitrogenated.

**Steel production.** Karl H. Moll and Harold Etherington (to A. O. Smith Corp.). U. S. 1,934,083, Nov. 7. A mixt. of flux, carbonaceous material and ore is charged into a shaft furnace, the carbonaceous material being sufficient to provide a C content in the melted Fe of about 0.3-1.5% and insufficient to provide for melting the Fe by combustion. A flame burning hydrocarbon material is blown on the charge at the bottom of the shaft for melting reduced Fe in the presence of the flux and carbonaceous material. A shallow zone is provided, contg. reduced Fe, flux and solid C, above the melting flame, by adding hydrocarbon gases to the ascending products of combustion a short distance above the flame in quantities sufficient to reduce the ore at the rate of melting and to reduce the temp. of the gases below sintering temps. of the unreduced ore. App. is described.

**Steel.** George F. Jaubert. Brit. 396,438, Aug. 1, 1933. Cylinders or bottles for storing compressed gases are made of steel contg. at least 98% Fe with C about 0.42, Ni about 0.02, Si at least 0.2 and S and P together about 0.006%, the remainder consisting of varying amts. of Mn, Si, Cr and Mo. The steels may be made by melting steel contg. C and Si with ferro-alloys contg. Mn, Cr, Ni and Mo prepd. in an elec. furnace or aluminothermically.

**Steels.** Établissements Jacob Holtzer. Fr. 41,646, Feb. 15, 1933. Addn. to 720,732 (C. A. 26, 1025). The process of Fr. 720,732 is applied to steels contg. Co 10-15, C about 0.75 and Cr 5-6%, with or without W 18%.

**Steels.** Akt.-Ges. vorm. Skodawerke in Pilsen. Fr. 749,503, July 26, 1933. The surface of austenitic steels and alloys is hardened by causing an instabilization of the  $\gamma$  phase at the surface, by removing from the surface the elements preserving the phase (C, Mn, Ni, Co, etc.) or introducing elements reducing the phase (Si, Al, P, As, Cr, Mo, V, Sn, Ti, etc.), so that the surface passes to other phases such as the martensite, pearlite, etc., while the core retains its original structure.

**Low-silicon steel strips.** James A. Sargent (to Sharon Steel Hoop Co.). U. S. 1,933,188, Oct. 31. In making low-Si steel strips with a dielectric surface coating, the metal is hot rolled and a hot rolled dielectric surface scale is formed on it, and the scale is then cold-rolled into the surface of the metal.

**Nitrided steel articles.** Edouard Houdremont (to Nitralloy Corp.). U. S. 1,934,672, Nov. 7. An alloy contg. Fe together with C 2, Cr 12 and W 0.8% is suitable for manuf. of articles such as dies, toothed wheels or bearings the surface of which may be nitrided.

**Nitrified steel.** Wilhelm Kroll. Ger. 577,637, June 2, 1933. Steel contg. Be is chilled and nitrified during the tempering process.

**Open-annealed steel and iron sheets.** Wm. H. Payne (to American Rolling Mill Co.). U. S. 1,932,560, Oct. 31. Sheets are first open-annealed and a thin scale is then formed over any exposed bare metal of the open-annealed product prior to pickling, by annealing the sheets at such low temps. that the product is not deprived of its open-annealed characteristics, and the sheets are then pickled.

**Silicon steel.** Edward M. Freeland. U. S. 1,932,306, Oct. 24. In making products such as "electrical steel" strip, the material is subjected to heavy reduction by cold-work, heated to remove part only of the strain thus imparted, cooled and then annealed. App. is described. U. S. 1,932,307 relates to a process involving casting a steel ingot of desired Si content and rolling it through passes extending in the same direction to form sheets of desired elec. properties. App. is described. U. S. 1,932,308 claims as a new product elec. strip steel contg. Si 2.75-3.5%, which may be produced as described in U. S. 1,932,306 and has a watt-loss property not more than about 1.1 watts per lb. in 24 gage thickness, decreasing as the thickness of the strip decreases.

**Electrical strip steel suitable for motors, dynamos, transformers, etc.** Edward M. Freeland. U. S. 1,932,-

309, Oct. 24. Steel contg. Si 3-6% may be treated as described in U. S. 1,932,306 (preceding abstr.) so that the watt-loss property of the resulting strip material is not more than about 0.98 watt per lb. in 24 gage thickness and decreases as the thickness of the strip decreases.

**Alloy steel for high-grade bore-hole casings such as those for oil wells.** Herbert Buchholtz (to Vereinigte Stahlwerke A.-G.). U. S. 1,931,717, Oct. 24. A steel is used contg. C 0.1-0.4, Si 0.7-1.0, Mn 0.9-2.0, Cr 0.2-0.9, Cu 0.7-1.5 and Al 0.1-0.2%, having a yield point 55 kg. per sq. mm., tensile strength 60 kg. per sq. mm., elongation 22%, reduction of area 58%, notched-bar tenacity 9 m. kg. per sq. cm., resistance to oscillation 40 kg. per sq. mm.

**Alloy steel.** Robert C. Becker and Franklin H. Allison, Jr. (to Crucible Steel Co. of America). U. S. 1,934,520, Nov. 7. An alloy steel having a "tool-proof" essentially austenitic structure which is not softened sufficiently by tempering to substantially decrease its tool resistance, and which is suitable for jail bars, etc., contains C 1.25-1.75, Cr 1-3, Mo. 1-3 and Ni 3.5-7.0%, the remainder being Fe except for elements present normally and in amounts not adversely affecting the characteristics of the alloy. Cf. C. A. 27, 4522.

**Heat-treating alloys.** Fried. Krupp A.-G. Brit. 396,383, July 31, 1933. Articles or parts of machinery that require a high strength at elevated temp., e. g., valves for internal combustion engines, are made from an austenite-martensitic transition alloy steel contg. C 0.3, Ni 10, Cr 4 and W 18. The Ni may be replaced wholly or partly by Mn and the W wholly or partly by Mo or V. The steel is first quenched from a sufficiently high temp. to give it an austenitic structure, e. g., 1200°, and is then reheated to above the austenite-martensitic crit. range, e. g., about 800°.

**Bearing alloy.** Metallhütten Schaefer & Schael A.-G. Ger. 577,772, June 3, 1933. A bearing alloy of the ternary system Sn-Sb-Pb contg. Cd consists of 10-55% Sn, 10-30% Sb, 0.2-3.0% Cd, 0.5-7.0% Ni and the remainder Pb. Cu and As may also be present in amts. of 3.0-3.5 and 0.5-1.0%, resp. The alloy is useful for locomotive bearings.

**Bearing metal.** Oskar Brandenberger. U. S. 1,934,586, Nov. 7. A bearing metal is formed of Cu, Sn, Zn, Pb and up to 4% S which serves to improve the durability.

**Hard alloys.** Wolfram & Molybdaen A.-G. Swiss 162,517 to 162,520. Sept. 1, 1933. A hard metal alloy contains a carbide such as TiC or TaC, and an alloy of metals of the 4th to 6th groups and of the Fe group fusing between 1500° and 2000°, such as Ni-W, Co-W, Fe-W, Fe-Co-W, Cr-Co-W, or Cr-Co (162,517). Hard tools are made from WC, 20% of a low-m. auxiliary metal such as Fe or Co and a carbide of a metal of the 4th to 6th groups convertible to a nitride, such as TiC, TaC or ZrC. These are sintered in an elec. furnace in an atm. of N (162,518). The WC may be sintered with a low-m. metal as before, but also with mixed crystals contg. a hard carbide such as TiN-TaC, TaN-TaC, TiN-TiC or TaN-TiC (162,519). Hard tools are also made by pressing and sintering a powder contg. a hard carbide such as WC and a low-m. metal such as Fe, Co or Ni (162,520). Cf. C. A. 27, 5710.

**Magnetic alloys.** The General Electric Co. Ltd. Ger. 581,673, Aug. 1, 1933. Addn. to 571,288 (C. A. 27, 3439). See Brit. 345,736 (C. A. 26, 418).

**Magnetic alloy.** Kinzokuzairyo Kenkyusho (Hakaru Masumoto, inventor). Fr. 749,713, July 28, 1933. Magnetic alloys for elec. app., etc., contain Si 0.5-16, Al 0.5-16% and Fe the rest. Ni, Co, Cr, W, Mo, Mn, V, Ti, Sn and Zn less than 10, Mg, Sb, Ta and Be less than 5 and B, Cu or P less than 2% may also be present to improve the magnetic properties and malleability.

**Sintered alloys.** Tool Metal Manufacturing Co. Ltd. Brit. 395,134, July 13, 1933. Addn. to 391,984 (C. A. 27, 5301). In a modification of the hard alloy for tools and working implements described in 391,984 the Ti carbide is wholly or partly replaced by another hard Ti compd., e. g., Ti nitride or boride or a mixt. of such compds.

**Alloy suitable for storage-battery terminals, etc.** Felix Nicodemus. U. S. 1,934,875, Nov. 14. In prepg. a corrosion-resisting alloy, a preliminary alloy contg. Sn, Sb and Cu is melted and then treated with Bi phosphate, ZnO and CuSO<sub>4</sub>, followed by the addn. of Hg, and the alloy thus prepd. is formed into articles such as battery posts without substantial change of temp.

**Aluminum alloys.** Robert T. Wood (to Aluminum Co. of America). U. S. 1,932,831, Oct. 31. An alloy which forms good castings contains Al together with Mg 2.9 and Ca 0.01-2.0%.

**Aluminum alloys.** Ludwig J. Weber (to Aluminum Co. of America). U. S. 1,932,835, Oct. 31. Alloys which have high resistance to corrosion contain Al together with Mg 0.4-2.0, Si 0.6-2.5 and Zr 0.1-1.0%, and are substantially free from Cu except as an impurity.

**Aluminum alloys.** Robert T. Wood and Otto H. Heil (to Aluminum Co. of America). U. S. 1,932,836, Oct. 31. Alloys which are suitable for casting comprise Al together with Mg 1.8, Zn 0.5-6.0 and Ca 0.1-2.0%.

**Aluminum alloys.** Robert T. Wood (to Aluminum Co. of America). U. S. 1,932,837, Oct. 31. Alloys which form good castings contain Al together with Mg about 1%, Mn about 0.5%, and Ca about 0.2%.

**Aluminum alloys.** Walter A. Dean and Louis W. Kempf (to Aluminum Co. of America). U. S. 1,932,838, Oct. 31. Alloys which have good properties at high temps. contain Al together with Mg 1.15 and Co 0.2-3.5%. U. S. 1,932,839 relates to alloys contg. Al together with Mg 3.0-7.5 and Ni 0.2-2.0%. U. S. 1,932,840 relates to alloys contg. Al together with Mg 3.8, Mn 0.5-4.0 and Ni 0.5-4.0%.

**Aluminum alloys.** Walter A. Dean and Louis W. Kempf (to Aluminum Co. of America). U. S. 1,932,841, Oct. 31. Alloys of high physical and tensile properties at elevated temps. and which are suitable for casting contain Al together with Mg 3.8, Mn 0.5-4.0, Ni 0.5-4.0 and Co 0.1-2.0%. U. S. 1,932,842 relates to otherwise similar alloys contg. Cr 0.1-2.0% instead of Co. U. S. 1,932,843 relates to similar alloys which may contain, instead of Co or Cr, about 0.1-0.75% of Ti, Zr, V, Mo or W. U. S. 1,932,844 relates to alloys similar to those of U. S. 1,932,841 contg. Cu 0.5-4.0%, instead of Co. U. S. 1,932,845 relates to alloys contg. Al together with Mg 3.0-7.5, Ni 0.2-2.0, and Sb or Bi (or a total of both) 0.05-0.4%. U. S. 1,932,846 relates to alloys contg. Al together with Mg 3.8, Mn 0.5-1.0, Ni 0.5-4.0 and Sb or Bi (or both together) 0.05-0.4%. U. S. 1,932,847 relates to otherwise similar alloys contg. also Cu 0.5-1.0%. U. S. 1,932,848 relates to alloys contg. Al together with Mg 2.15, and Sb or Bi (or both together) 0.05-0.1%. U. S. 1,932,849 relates to alloys of Al with Mg 3.8, Ni 0.5-4.0 and Co 0.1-3.0%. U. S. 1,932,850 relates to alloys of Al with Mg 3.8, Ni 0.5-3.5, Cr 0.3-3.5 and Sb or Bi (or a total of both) 0.05-0.1%. U. S. 1,932,851 specifies Al together with Mg 3.8, Ni 0.5-5.0, Cu 1.6 and Sb or Bi (or both together) 0.05-0.4%. U. S. 1,932,852 specifies Al together with Mg 3.8, Ni 0.5-4.0, Co 0.1-3.0 and Sb or Bi (or both) 0.05-0.4%. U. S. 1,932,853 specifies Al together with Mg 3.8, Cu 1.6, Cr 0.5-3.5 and Sb or Bi (or both) 0.05-0.4%.

**Aluminum alloys.** Robert T. Wood (to Aluminum Co. of America). U. S. 1,932,854, Oct. 31. Alloys which are suitable for casting contain Al together with Mg 2.10, Ni 0.2-5.0 and Ca 0.05-2.0%. U. S. 1,932,855 relates to alloys of Al with Mg 3.0-7.5, Ni 0.2-2.0, Sb or Bi (or both) 0.05-0.4 and Ca 0.05-2.0%. U. S. 1,932,856 specifies Al with Mg 3.8, Ni 0.5-4.0, Mn 0.5-1.0 and Ca 0.05-2.0%. U. S. 1,932,857 relates to similar alloys contg. also Sb or Bi (or both) 0.05-0.1%. U. S. 1,932,858 relates to alloys contg. Al together with Mg 2.15, Sb or Bi (or both) 0.05-0.4 and Ca 0.05-2.0%. U. S. 1,932,859 specifies Al together with Mg 2.10, Ni 0.2-5.0, Cr 0.5-3.5 and Ca 0.05-2.0%. U. S. 1,932,860 specifies Al together with Mg 3.8, Ni 0.5-3.5, Cr 0.5-3.5, Sb or Bi (or both) 0.05-2.0 and Ca 0.05-2.0%. U. S. 1,932,861 specifies Al together with Mg 2.10, Ni 0.2-5.0, Cu 1.6 and Ca 0.05-

2.0%. U. S. 1,932,862 specifies Al together with Mg 3-8, Ni 0.5-5.0, Cu 1.6, Sb or Bi or both 0.05-0.4 and Ca 0.05-2.0%. U. S. 1,932,863 specifies Al together with Mg 3-8, Ni 0.5-5.0, Co 0.5-3.5, Cu 0.5-5.0 and Ca 0.05-2.0%. U. S. 1,932,864 specifies Al together with Mg 3-8, Ni 0.5-5.0, Cu 1.6, one or more of the elements W, V, Mo, Ti and Zr 0.1-1.0, and Ca 0.05-2.0%. U. S. 1,932,865 specifies Al together with Mg 2-10, Ni 0.2-5.0, Co 0.1-3.5 and Ca 0.05-2.0%. U. S. 1,932,866 specifies Al together with Mg 3-8, Cr 0.5-3.5, Cu 1.6 and Ca 0.05-2.0%. U. S. 1,932,867 specifies Al together with Mg 3-8, Cr 0.5-3.5, Sb or Bi (or both) 0.05-0.4, Cu 1.6 and Ca 0.05-2.0%. U. S. 1,932,868 specifies Al together with Mg 3.8, Sb or Bi or both 0.05-0.4, Ni 0.5-4.0, Co 0.1-3.0 and Ca 0.05-2.0%. U. S. 1,932,869 specifies Al together with Mg 2.15, Co 0.1-3.5, Sb or Bi or both 0.05-0.4 and Ca 0.05-2.0%.

**Aluminum alloys.** Robert T. Wood (to Aluminum Co. of America). U. S. 1,932,870, Oct. 31. Alloys which are suitable for casting contain Al together with Mg 3.8, Ni 0.5-5.0, Cr 0.5-3.5, Cu 0.5-5.0 and Ca 0.05-2.0%. U. S. 1,932,871 specifies Al together with Mg 2.15, Co 0.1-3.5 and Ca 0.05-2.0%. U. S. 1,932,872 specifies Al with Mg 2.9, Ca 0.05-2.0, Mn 0.1-4.0 and Sb or Bi or both 0.05-0.4%.

**Aluminum alloys.** Walter A. Dean and Louis W. Kempf (to Aluminum Co. of America). U. S. 1,932,873, Oct. 31. Alloys of high phys. and tensile properties at elevated temps. and which are suitable for casting contain Al together with Mg 1.15, Co 0.2-3.5 and Sb or Bi or both 0.05-0.4%.

**Aluminum alloy.** Akt.-Ges. vorm. Skodawerke in Pilsen. Swiss 160,811, June 1, 1933. An alloy contains 15.9% Si, 3.10% Zn, 1.5-6% Cu, 1-2.5% Fe, 0.2-1.5% Mn, 0.05-1% Mg and the rest Al. Small amts. of Cr, Pb, Ni, Sn, Cd, Sb and Ti may be added. The product has good casting properties.

**Aluminum alloys.** Aluminium Ltd. Fr. 749,415, July 24, 1933. See Brit. 391,737 (C. A. 27, 5302).

**Corrosion resistant aluminum alloy.** Wm. E. McCullough (to Bohn Aluminum & Brass Corp.). U. S. 1,932,795, Oct. 31. An alloy which is suitable for exposure to the weather contains Al together with Cu 0.05-0.5, Cr 0.75-1.5, Co 0.25-0.5, Si 0.75-3.0 and Mg 0.5-1.25%. Cf. C. A. 27, 4209.

**Aluminum-magnesium alloys.** Aluminium Ltd. Fr. 749,451, July 25, 1933. Satisfactory castings of Al-Mg alloys contg. 5-20% of Mg are obtained by using Al which contains less than 0.8% of impurities and by using a molding material, e. g., sand contg. boric acid and an aq. soln. of diethyleneglycol, which will produce a protective vapor against the atm. around the hot metal.

**Aluminum-silicon alloy.** Theron D. Stay (to Aluminum Co. of America). U. S. 1,932,281, Nov. 7. An alloy which can be cast with substantial freedom from surface shrink or draws contains Al together with Si 3-15 and Ti 0.1-0.5%.

**Barium-aluminum alloy.** Egyesült Izzólámpa és Villamossági R. T. Brit. 395,989, July 27, 1933. A light alloy contains Ba 80-90 and Al 10-20% and may be made by the thermo-aluminic reduction of BaO, the reduced Ba alloying with the excess Al. The alloy may be used in discharge lamps for the removal of residual gases and for the activation of cathodes.

**Cobalt-tungsten alloys.** Vereinigte Stahlwerke A.-G. Brit. 396,380, July 25, 1933. Addn. to 356,080 (C. A. 26, 3226). The heat treatment described in 356,080 is applied to alloys contg. Co 41-85, W upward of 5, the Co and W amounting to at least 80, and Cr up to 40%. The Cr may be partially replaced by Fe up to 35% of the latter and the alloys may contain 5% of Mo, Mn, Ni, Cu, Al, V and (or) Ti. In an example an alloy of Co 49, W 38, Cr 12, V 1 and C 0.1% is quenched from 1200° and annealed at 800°.

**Copper alloy.** Kenneth W. Ray and Howard W. Gould (to American Brass Co.). U. S. 1,933,390, Oct. 31. An alloy which can readily be cast and worked contains Cu 82

and Si 3%, the remainder being substantially all Zn. *Cf. C. A. 27, 5302.*

**Copper alloys.** Theodor Laible. Swiss 162,791, Sept. 1, 1933. Fused Cu alloys are purified by adding wood charcoal dust and an alkali pyrosulfate to the fused mass. One part of a mixt. contg. 90%  $\text{Na}_2\text{S}_2\text{O}_7$  and 10% C is added to 100 parts of fused alloy.

**Thermal treatment of copper-nickel alloys.** Vereinigte Deutsche Metallwerke A.-G. (Eugen Vaders, inventor). Ger. 586,338, Oct. 20, 1933. Alloys contg. Cu 50-90, Ni 5-40, Fe 0.5-10 and Al 0.5-5% are heated at 700-900° for about 3 hrs. and then cooled gradually to atm. temp. Alloys of improved mech. properties are obtained.

**Iron-nickel-beryllium alloys.** Siemens & Halske A.-G. and Wilhelm Kroll. Fr. 41,574, Feb. 7, 1933. Addn. to 609,551 (*C. A. 24, 1838*). The mech. properties of alloys contg. Fe, Ni and Be, contg. 20% or more of Ni and Cr, are improved by cooling rapidly from 800-1200° and artificially aging by heating to 700-850°.

**Ferrous alloy carburizing boxes.** Harry L. Frevort and Francis B. Foley. U. S. 1,933,900, Nov. 7. Carburizing boxes are formed of an alloy contg. Fe together with C 0.05-1.2, Mn 2-10, Si 0.25-5.0, Cr 20-45, Cu 5-15 and Al 1-5%.

**Refining magnesium and its alloys.** Frederick Badger. U. S. 1,935,284, Nov. 14.  $\text{MgF}_2$  and hydrated Mg chloride are added to the metal to be melted to protect it from oxidation and effect refining. App. is described.

**Zinc alloys.** Leland E. Wemple and John R. Daesen. U. S. 1,933,490, Oct. 31. Alloys which are suitable for use in polished sheet form contain Zn together with Cu 0.025-0.245 and Ag 0.001-0.245%.

**Coating metals.** Horace Campbell Hall. Brit. 396,746, Aug. 4, 1933. A protective coating is formed on non-ferrous metals and alloys, particularly high Al alloys, by immersion in a hot soln. of  $\text{H}_3\text{PO}_4$  in ethylene glycol, glycerol and (or) trimethylene glycol. The coated articles are washed, preferably in dil. alk. soln., and may then be tumbled in air or oil a few hrs. at 100-200°. The coating may be used as a base for paint, varnish or enamel.

**Coating metal surfaces.** Francis H. Snyder and Stanley F. M. McLaren (to Industrial Research, Ltd.). U. S. 1,932,713, Oct. 31. Cleaned metal surfaces such as iron or steel are prepd. for coating with a metal or alloy of low m. p. by immersion in a molten bath of a Pb salt of a non-soap-forming fatty acid such as Pb acetate or propionate.

**Protective coating for metals.** Heinrich Klas (to Vereinigte Stahlwerke A.-G.). U. S. 1,932,699, Oct. 31. Metal surfaces are treated with a compn. comprising a soln. of induratable artificial resins in tar oil and an org. substance such as anthracene b. above 300°, while heating.

**Applying metal coatings such as lead to steel strips or the like.** David R. Ward (to Youngstown Sheet and Tube Co.). U. S. 1,933,401, Oct. 31. The material to be coated is passed through a molten bath of the coating metal, and, while the coating is still at a high temp., it is confined and compressed and is cooled in a non-oxidizing atm. App. is described.

**Apparatus for tinning metal sheets or plates in a bath of molten metal.** Claude A. Bollinger and John P. Rodgers (to American Sheet and Tin Plate Co.). U. S. 1,933,136, Oct. 31. Various details are described of an app. with sheet feeding rolls in an oil bath and soapstone "brushes" for at least one pair of the rolls.

**Coating galvanized surfaces.** Hans Hofer. Swiss

162,214, Sept. 1, 1933. Surfaces coated with Zn are roughened and coated, e. g., with lacquer or a mixt. of cement, lime and water.

**Apparatus for passing wire or metal strip through plating baths, etc.** Felix Kleiss. Ger. 586,121, Oct. 18, 1933.

**Babbitt-lined journal bearing shell.** Fred C. Jones and Richard W. Funk (to Bohn Aluminum & Brass Corp.). U. S. 1,932,787, Oct. 31. A lined bearing shell comprises a shell element formed of extruded bronze having less than 75% Cu content and of high thermal cond., and a thin lining of softer metal such as babbitt metal integrated with the shell to be in high thermal conductive relation to the shell for rapid dissipation of heat.

**Rotary percussive drills.** Tool Metal Manufacturing Co. Ltd. Brit. 396,943, Aug. 17, 1933. Inserted cutters for rotary percussive drills are made of a sintered alloy of "hard metal" with 5-12% of a softer metal, e. g., Fe, Co, Ni, Mn. "Hard metals" are borides, carbides, nitrides or silicides of W, Mo, Ta, B or Ti. An example is W carbide 92 and Co 8%.

**Saw blades.** Universal Steel Co. Brit. 397,151, Aug. 18, 1933. Hacksaw blades are made from steel contg. Cr 3-12 and W 2-12%, with or without V up to 3%, and contg. also embedded abrasive nodules of cementite. The C may be 0.7-1.3%. The sheets are annealed at 1425-1475° for about 18 hrs., cooled slowly and cut into blades which are hardened by heating just above the crit. point and quenching in oil and are afterward tempered.

**Method of sharpening files, rasps, etc., by treatment with mineral acid.** Hans Ludwig. Ger. 586,232, Oct. 21, 1933.

**Apparatus for welding, etc.** Sally Sandelowsky (to General Elec. Co.). U. S. 1,933,343, Oct. 31. Electrodes formed mainly of Ta carbide are used with their arcing terminals surrounded by a hydrocarbon gas. Zr and Hf carbides also may be used.

**Welding electrodes.** N. V. Machinerieën-en Apparaten Fabrieken. Brit. 396,331, Aug. 3, 1933. The core of a coated electrode for arc welding soft, alloy and other steels consists of acid Siemen's-Martin steel. A C steel may be used, deoxidizing and alloying substances being contained in the coating or wholly or in part alloyed with the core metal. The core should contain not more than 0.015% S. The deoxidizing substances may consist of Fe-Mn, Fe-Si, Mn, Si, Carborundum, Cr, Ni or Mo.

**Welding compositions.** I. G. Farbenind. A.-G. (Leo Schlecht, Walter Schubardt and Franz Duftschmidt, inventors). Ger. 581,749, Aug. 2, 1933. Addn. to 580,398 (*C. A. 27, 4770*). Powd. metals obtained from metal carboxyls are used in prepg. the compns. described in Ger. 580,398, with or without powd. metals otherwise obtained.

**Welding powder.** Pio Rossi. Swiss 161,102, June 16, 1933. A powder for autogenic welding of Al consists of a mixt. of KCl, LiCl and alkali metal sulfate.

**Uniting different pieces of "duralumin."** Wolfgang B. Klemperer (to Goodyear-Zeppelin Corp.). U. S. 1,934,673, Nov. 7. Substantially pure unalloyed Al is used as an intermediate material in forming a unitary welded joint.

**Solder for aluminum.** Friedrich Strasser. Swiss 162,522, Sept. 1, 1933. A solder for Al and its alloys contains Al, Zn, Sn and up to 20% Ag. *Cf. C. A. 27, 4770.*

**Melting pot for soldering ends of wires together.** Earl G. Klock (to The British Thomson-Houston Co. Ltd.). Brit. 396,420, July 24, 1933.

## 10 ORGANIC CHEMISTRY

CHAS. A. ROUILLE and CLARENCE J. WEST

**Molecular distillation in the organic laboratory.** F. A. Skishakov. *Uspekhi Khim.* 2, 354-60 (1933); *cf. Hill, C. A. 26, 5319; Hickman, C. A. 26, 1833; F. H. R.*

**The manufacturing processes for liquid organic products from industrial gases.** Étienne Audibert. *Ann. com-*

*hustibles liquides* 8, 757-869 (1933).—The manuf. of liquid org. products from CO and  $\text{CH}_4$  is discussed. The following subjects are presented: (1) thermodynamic study of the hydrogenation of CO, (2) catalytic hydrogenation of CO at atm. pressure, and (3) under pressure,

(4) MeOH synthesis from CO, (5) the pyrolysis of CH<sub>4</sub>, and (6) partial oxidation of CH<sub>4</sub>. Considerable data are presented for each subject. K. K.

**The principles of thermal decomposition and hydrogenation of organic compounds.** Étienne Audibert. *Ann. combustibles liquides* 8, 565 605 (1933).—The article deals with primary reactions of paraffins, cyclic hydrocarbons, hydroaromatics, olefins and aromatics, with superimposed reactions and catalytic cracking. Berthelot's hydrogenation method and Sabatier's discoveries and their applications are also discussed. K. K.

**Isoparaffins of high molecular weight.** Hermann Suida and Rudolf Planckh. *Ber.* 66B, 1445 54 (1933).—The known pure isoparaffins with 13 or more C atoms are tabulated with their phys. properties, and classified as end-branched (I), middle-branched (II) and multiple-branched (III), the side chains being attached, resp., at the  $\beta$ -C atom, at any other atom, and at 2 or more points. For a detn. of structure from phys. properties, the value of mol. wt. times  $n_0^{1/3}$  is the most useful. These values for the  $n$ -paraffins agree to 0.1 with those calcd. from 20.445 for CH<sub>2</sub> and 7.06 for H<sub>2</sub>, whereas values found for I are less, for II greater and for III either more or less than calcd.; large increments are shown by naphthenes and paraffin waxes. Attempts to synthesize isoparaffins from (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>CIII (from (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>CHOH, m. 33.5°,  $d_4^{20}$  0.9692,  $n_D^{20}$  1.4596) failed. However, (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>CO and MeMgBr give (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>C(OH)Me (m. 40.1°,  $d_4^{20}$  0.8292,  $d_4^{25}$  0.8085,  $n_D^{20}$  1.4503,  $n_D^{25}$  1.4408), from which, via the iodide, is obtained (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>CIMe (IV), m. 32.1°,  $d_4^{20}$  0.8214,  $d_4^{25}$  0.7821,  $n_D^{20}$  1.4517,  $n_D^{25}$  1.4395. Similarly obtained are (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>C(OH)Et, m. 37.8°,  $d_4^{20}$  0.8135,  $n_D^{20}$  1.4414. (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>CH<sub>2</sub>Me, m. about 18°,  $d_4^{20}$  0.8214,  $d_4^{25}$  0.8001,  $n_D^{20}$  0.7934,  $d_4^{25}$  0.7666,  $n_D^{20}$  1.4583,  $n_D^{25}$  1.4469,  $n_D^{20}$  1.4404. (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>C(OH)Bu, m. 16.8°,  $d_4^{20}$  0.8219,  $d_4^{25}$  0.7996,  $n_D^{20}$  1.4417. (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>(HBr) (V), m. about 23°,  $d_4^{20}$  0.8263,  $d_4^{25}$  0.8206,  $d_4^{20}$  0.7913,  $n_D^{20}$  1.4602,  $n_D^{25}$  1.4579,  $n_D^{20}$  1.4425,  $n_D^{25}$  1.4108, viscosity (100  $\eta$ ) from 42.01 at 20° to 4.11 at 100°. (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>C(C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>, m. 16.7°,  $d_4^{20}$  0.8116,  $d_4^{25}$  0.7811,  $n_D^{20}$  1.4450. (C<sub>15</sub>H<sub>31</sub>)<sub>2</sub>CHC<sub>15</sub>H<sub>31</sub>, m. 45.5–46°,  $n_D^{20}$  1.4450. Dipentacyclononylcyclononol is not formed by this method. IV and V on distn. at 1 atm. yield cryst. paraffins, m. 68.9° and 62.3°, resp.; V is decompd. by ClSO<sub>3</sub>H and SbCl<sub>5</sub>. H. A. Beatty

**1,4-Addition and subtraction reactions in hydrocarbon chemistry.** Louis S. Kassel. *J. Chem. Physics* 1, 749 50 (1933). Qual. quantum mech. arguments show that the activation energy for 1,4-dehydrogenation of 2-butene should differ little from that for 1,2-dehydrogenation of a paraffin. The model used for the former reaction applies also to butane, the products then being H<sub>2</sub> + 2C<sub>2</sub>H<sub>2</sub>; 1,4-loss of methane, ethane, etc., is predicted by analogy. These reactions should occur in the pyrolysis of paraffins with chains of at least 4 C atoms. The results of Frev and Hepp (*C. A.* 27, 2670) are interpreted as well in this way as by the free radical chains of Rice (*C. A.* 27, 3910). Morris Muskat

**The chemical constitution of nitric acid esters.** A. Majrich. *Chimie & industrie Special No.*, 727 35 (June, 1933). From a study of the sapon. of various HNO<sub>3</sub> esters by means of NaHSO<sub>3</sub> and Na<sub>2</sub>S, M. concludes that, of the 3 types of formula which have been suggested, the most probable is RCH<sub>2</sub>OONO. A. P.-C.

**Action of concentrated aqueous sodium hydroxide solution on nitromethane.** H. Shupley Fry and Joseph F. Treon. *Rec. trav. chim.* 52, 827 32 (1933).—Each reaction mixt. contained 13.34 cc. of pure MeNO<sub>2</sub> and 250 cc. of aq. NaOH (5, 10, 15 N), and was heated in a 500-cc. Cu flask in an oil bath at 130–40° for 10 hrs. The yields of Na<sub>2</sub>CO<sub>3</sub> and NH<sub>3</sub> showed that 48% of the MeNO<sub>2</sub> underwent an oxidation-reduction reaction which was practically 100% in conformity with the equation: MeNO<sub>2</sub> + 2NaOH  $\rightarrow$  Na<sub>2</sub>CO<sub>3</sub> + NH<sub>3</sub> + H<sub>2</sub>O. L. K.

**The condensation of sulfamide, dimethylsulfamide, and aniline-*p*-sulfonamide with formaldehyde.** Frederick C. Wood and Albert E. Battye. *J. Soc. Chem. Ind.* 52,

1 346 9T (1933).—SO<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub> (m. 92–3°; best prepd. by the method of Ephraïm (*C. A.* 4, 1000)) with 2–4 mol. parts CH<sub>2</sub>O at  $p_H$  4–7.5 and room temp., forms a clear, hard, photostable resin, insol. in org. solvents, hydrolyzed by boiling H<sub>2</sub>O to amorphous SO<sub>2</sub>[N(CH<sub>2</sub>OH)]<sub>2</sub>. NH<sub>2</sub>SO<sub>2</sub>NMe<sub>2</sub>, CH<sub>2</sub>O and a trace of HCl give in 2–3 days a cryst. anhydride of Me<sub>2</sub>NSO<sub>2</sub>N(CH<sub>2</sub>OH)<sub>2</sub>, m. 185° (decompn.), insol. in boiling water and org. solvents. *p*-NH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>NH<sub>2</sub> and CH<sub>2</sub>O yield, probably, a mixt. of *p*-CH<sub>2</sub>:NC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>NH<sub>2</sub> and *p*-NH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>NHCH<sub>2</sub>OH. H. A. Beatty

**Esters of tetrathioorthosilicic acid.** II. H. J. Backer and F. Stenstra. *Rec. trav. chim.* 52, 912 15 (1933).—The compds. Bu, sec-Bu, iso-Bu, Ph and *p*-tolyl tetrathioorthosilicates have been prepd. and identified analytically. The b. p.,  $n$  and  $d$  are given for each. *tert*-Bu mercaptide gives a trithiosilicate, showing that but 3 Cl atoms of SiCl<sub>4</sub> are replaceable in some cases in this reaction. R. H. Lambert

**Simple esters of tetrathioorthostannic acid.** H. J. Backer and J. Kramer. *Rec. trav. chim.* 52, 916 22 (1933). The prepn. of esters of tetrathioorthostannic acid has been accomplished in several ways. Those described are the Me, Et, Pr, iso-Pr, Bu, iso-Bu, *tert*-Bu, and *tert* Am esters. The crystals of these compds. are described. The fact that substances having filled mols. have higher m. ps. than those of mols. less compact or less sym. is again exemplified. R. H. Lambert

**The action of sodium on aliphatic diazo compounds.** Eugen Müller and Helmut Disselhoff. *Naturwissenschaften* 21, 661 (1933). Metallic Na will give gas evolution and finally complete decolorization of an ether soln. of CH<sub>2</sub>N<sub>2</sub>. CH<sub>2</sub>N<sub>2</sub> free of EtOH and H<sub>2</sub>O (Arndt, *C. A.* 24, 3985) was decompd. by Ph<sub>3</sub>CNa under N<sub>2</sub>. The ppt. washed with abs. Et<sub>2</sub>O and decompd. with H<sub>2</sub>O yielded part of the CH<sub>2</sub>N<sub>2</sub> back. A Na compd. of CH<sub>2</sub>N<sub>2</sub> could not be isolated; the ether-dry prepn. exploded in N<sub>2</sub>. It reacted vigorously with BzCl, giving C<sub>6</sub>H<sub>5</sub>ON<sub>2</sub>, not identical with N<sub>2</sub>HCCOPh. PhCN<sub>2</sub> also reacts with Ph<sub>3</sub>CNa without gas evolution, forming an ether-sol compd. which on decompn. with H<sub>2</sub>O yields C<sub>6</sub>H<sub>5</sub>I<sub>2</sub>N<sub>2</sub> (M = 106) and which is not identical with (Ph<sub>2</sub>C=N)<sub>2</sub>. The reactions are similar to the decolorization of PhN<sub>3</sub> by Ph<sub>3</sub>CNa (cf. Hantzsch and Lehmann, *Ber.* 34, 2522 (1901)). B. J. C. van der Hoeven

**New process for concentrating acetic acid.** Bruno v. Tetmajer. *Chimie & industrie Special No.*, 866 7 (June, 1933); cf. *C. A.* 26, 1127. The merits of the Clamecy process, revealed by several yrs. operation at the plant of the Soc. des Produits Chimiques de Clamecy, are brought out. A. Papineau-Couture

**Acetic acid dehydration.** Donald F. Othmer. *Am. Inst. Chem. Eng.*, Roanoke Meeting, Dec., 1933 (preprint), 17 pp. The paper classifies by types some of the methods proposed and in use for removing part or all of the water from an AcOH soln. Only a few of the many processes available are discussed, but the general theories are compared. The chem. processes, distn., extn., refrigeration and other methods are given. C. L. Mantell

**Addition of hydrogen bromide to olefinic acids.** R. P. Linstead and H. N. Rydon. *Nature* 132, 643 (1933); cf. *C. A.* 27, 4214. Expts. with allylacetic acid (I) indicate that the peroxide effect, as suggested by Kharasch (*C. A.* 27, 3444) for explaining the direction of addn. of HBr to allyl and vinyl bromides, is of secondary importance here. Addn. of HBr to I in hexane normally yields pure  $\delta$ -bromovaleric acid; L. and R. have been unable to reverse this in the presence of H<sub>2</sub>, Ph<sub>2</sub>NH or hydroquinone. Both freshly prepd. I and a very stale sample which gave a strong peroxide reaction yielded  $\gamma$ -bromovaleric acid in the absence of solvent. Reversal of the addn. of HBr to I in the absence of solvent can be induced by addn. of Bz<sub>2</sub>O<sub>2</sub>, which gives the  $\delta$ -Br acid. Apparently the importance of the peroxide effect varies with different unsatd. acids and cannot account for the influence of the solvent on the addn. of HBr to I. Louise Kelley

**Synthesis of nonadecylic acid.** Shiehirō Shiina. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 569 (1933).— $C_{19}H_{39}COOH$  was synthesized by the following scheme: Et stearate  $\rightarrow$  octadecyl alc.  $\rightarrow$  octadecyl iodide  $\rightarrow$  octadecyl cyanide  $\rightarrow$  nonadecylic acid. The m. p. of the acid was found to be 68.2–84°.

**Chloroacetic acid.** G. A. Kirkhof and A. I. Zilberg. *Khim. Farm. Prom.* 1933, 192 3. —The difficulties of distn. are eliminated by chlorinating in porous clay vessels with Schott's gas distributor. The reaction is complete when the gravity reaches 36° B $\phi$ .

**The more recent literature on ethylene oxide.** II. H. Kemper. *Z. Gesundheitstsch. Stadtehyg.* 25, 341 6 (1933); cf. *C. A.* 27, 5296.—A review. Forty-eight references.

**Industrial process for the manufacture of ethylene oxide and ethylene glycol.** Jacques Françon. *Chimie & Industrie Special No.*, 869 75 (June, 1933); cf. Leulier, *C. A.* 26, 23.  $C_2H_4$  can be oxidized directly to pure  $C_2H_4O$  and  $CO_2$  by using a sp. catalyst, the nature of which is not specified beyond stating that it is a binary mixt., one of the constituents of which acts as an activator. Lab. expts. carried out on a product obtained by dehydration of EtOH and contg. 92%  $C_2H_4$  showed that: (1) the optimum air: $C_2H_4$  ratio is 10; (2) the optimum temp. is 375°; (3) injection of  $H_2O$  reduces the production of both  $C_2H_4O$  and  $CO_2$ , but the latter to a greater extent than the former; (4) formation of  $CO_2$  is not due to oxidation of  $C_2H_4O$  but to the direct oxidation of  $C_2H_4$ ; (5) with a tube 2.3 mm. in internal diam., the optimum rate of flow of gas is 80 l. per hr.; with lower rates the production of both  $C_2H_4O$  and  $CO_2$  falls off slightly; with higher rates the production of  $C_2H_4O$  falls while that of  $CO_2$  remains practically const.; (6) with different sized tubes, the optimum rate of flow is proportional to the cross section of the tube; (7) at the optimum rate of flow, reducing the air: $C_2H_4$  ratio (below 10) rapidly reduces the formation of  $C_2H_4O$ , while that of  $CO_2$  remains const. or tends to increase; (8) reducing the temp. below 375° rapidly reduces the production of  $C_2H_4O$  and has but little effect on that of  $CO_2$ ; increasing it above 375° accelerates both reactions, the formation of  $CO_2$  increasing more rapidly than that of  $C_2H_4O$ ; (9) increasing the pressure up to 50 kg. per sq. cm. decreases the production of  $C_2H_4O$  and increases the production of  $CO_2$ , possibly because of partial combustion of the  $C_2H_4O$ . Ordinary purified coke-oven gases still contain S and P compds. and about 2%  $C_2H_2$ , which poison the catalyst and which can be satisfactorily purified by passing over CuO at 150–200°. From a discussion of the industrial application of the process, it is concluded that this can be successfully carried out with purified coke-oven gases, by using an air: $C_2H_4$  ratio of 1:3, adding about 5% pure  $O_2$  to the mixt., and passing the mixt. successively through a series of tubes contg. catalyst of increasing degree of activity.

**Formation of the chlorohydrins.** VI. A few higher homologs of ethylene chlorohydrin. Harald Nilsson and Lennart Smith. *Z. physik. Chem.* A166, 136 46 (1933); cf. *C. A.* 14, 2629.—The alk. and neutral decompn. of  $\alpha$ -dimethyl-, trimethyl-, tetramethyl- and  $\alpha$ -diethyl-ethylene chlorohydrin were investigated. G. M. M.

**Action of phosphorus tribromide on ethylenic  $\alpha$ -hydroxy nitriles.** R. Rambaud. *Compt. rend.* 197, 689 91 (1933). When  $PBr_3$  was added to vinylglycolonitrile,  $CH_2=CHCH(OH)CN$ , in  $CCl_4$  or dry  $Et_2O$ , an intramol. rearrangement occurred and propionyl cyanide,  $EtCOCN$  (b. 109–110°,  $d_4^{20}$  0.958,  $n_D^{20}$  1.392, was formed. Most of the  $PBr_3$  was recovered unchanged by distn. I. added to water, reacted with evolution of heat, forming  $H_2CO_2$  and HCN.  $\alpha$ -Hydroxypentenic nitrile,  $MeCH=CHCH(OH)CN$ , b. 108–109°,  $d_{15}^{20}$  0.980,  $n_D^{20}$  1.4415, was prepd. and found to behave like vinylglycolonitrile in the above reactions. L. E. Gilson.

**Ether-like compounds.** XI. An ether lactone with a seven-membered ring. M. H. Palomaa and Unto Toukola. *Ber.* 66B, 1629–32 (1933); cf. *C. A.* 27,

3698.—( $\gamma$ -Methoxypropoxy)acetic acid, prepd. from  $MeOCH_2CH_2CH_2OH$  in the usual way, b. 140–141°,  $d_4^{20}$  1.1240, 1.1164, 1.1110 at 10°, 20° and 30°,  $n_D^{20}$  1.43484, 1.43693, 1.44293, 1.44653 for  $\alpha$ ,  $D$ ,  $\beta$  and  $\gamma$  at 20°; with  $HBr$  it gives the  $\gamma$ -HO acid (I) but it is difficult to obtain the product free of halogen and I was obtained in purer form from 1 atom Na, 4 mols.  $CH_2(CH_2OH)_2$  and 0.5 mol.  $ClCH_2CO_2H$ . The excess of glycol was removed by vacuum and steam distn., and since I is extraordinarily little sol. in ether the soln. was evapd. to dryness, taken up in fuming  $HCl$  and dioxane, treated with a current of  $H$  for some hrs., filtered from the  $NaCl$ , freed from the dioxane and water by distn. *in vacuo*, purified by alternate addn. of small amts. of water and distn. *in vacuo*, and finally distd. *in vacuo*. If the bath temp. is kept at 90–100° and air is passed through the liquid under about 1 mm. pressure, 3 distns. give a thick oil consisting of I and its lactone; at a sufficiently high temp. this is converted largely into the lactone, m. 135.2–6.0°, mol. wt. in freezing benzene 121, sol. in hot water with neutral reaction. The hydrolysis velocity was measured in  $H_2O$ - $Me_2CO$  (1:1 by vol.) at 25° and in water-dioxane at 25° and 35° with  $HCl$  as catalyst (concn. of lactone, around 0.025  $N$ ; of  $HCl$ , about 0.1 and 0.2  $N$ ). The hydrolysis const. (time in min.) reduced to 1  $N$   $HCl$  as catalyst is  $k_{25}$  0.0091 in  $H_2O$ - $Me_2CO$  and  $k_{35}$  0.00478 and  $k_{25}$  0.0104 in water-dioxane. C. A. R.

**Condensation of bromal hydrate with aliphatic amides.** R. H. Velburgi. *J. Indian Chem. Soc.* 10, 383 90 (1933). The  $Ac$  (I),  $Bz$  (II), anhydro (III),  $\beta$ -tribromo- $\alpha$ -chloroethyl (IV), and  $Me$  (V) derivs. of  $RCONHCH(OH)CH_2Br$  (VI) were prepd. M. and b. ps.:  $R = H$ , VI 139–40°, I 107–8°, II 139°, III chars 160°, m. 170°, IV b. 80°,  $R = Me$ , II 122°, III 183–5°, IV b. 76°, chloroamide of IV b. 138°,  $R = Et$ , VI 171°, I 96–8°, II 113–15°, III 192°, IV b. 120°, V 85–7°,  $R = Pr$ , I 96–8°, II 122°, III 155°, IV b. 126°, V 101°;  $R = iso-Pr$ , VI 156°, I 141–3°, II 131–2°, III 155°, V 135°;  $R = iso-Bu$ , VI 149°, I 110–2°, II 98–100°, III 130–2°, V 115–17°;  $R = C_2H_5$ , VI 146°, I 120–2°, II 132–4°, III 153°, V 105–7°;  $R = C_6H_5$ , VI 142°, I 135–6°, II 126°, V 93–5°;  $R = C_6H_{11}$ , VI 139°, I 120°, II 108–10°, III 166°, V 85°;  $R = C_6H_{13}$ , VI 139°, I 121°, II 123–6°, V 72–4°. When VI was reduced with  $HOAc$  and  $Zn$  dust the corresponding  $\beta$ -dibromoethylene derivs. with the following m. ps. were obtained:  $R = Et$ , 84–6°;  $Pr$ , 78–80°;  $iso-Pr$ , 80–2°;  $iso-Bu$ , 68–70°;  $C_6H_{11}$ , m. 74–5°;  $C_6H_{13}$ , m. 115°;  $C_6H_{17}$ , m. 63–4°. M. ps. of mono- $Br$  derivs.:  $R = C_6H_{11}$ , 61–3°;  $C_6H_{13}$ , 67–71°;  $C_6H_{17}$ , b. 148°. J. W.

**Synthesis of succinic acid.** M. S. Rozhdvestvenskii, B. A. Slasenna and N. O. Valter. *Khim. Farm. Prom.* 1933, 117–20. Tech. tartaric acid (960 g.), 240 g. of red P, 144 g. of I and 960 cc. of 96%  $AcOH$  are heated slowly in a 5-l. flask, with agitation, to 100–105°. The temp. is raised to 140° and the mixt. refluxed for 3 hrs.; then most of  $AcOH$  is distd. off, the mixt. dissolved in hot  $H_2O$ , filtered with activated charcoal, cooled and the crystals of succinic acid are filtered and washed with  $H_2O$  at 4°. The I is regenerated. L. N.

**The velocity of alcoholysis of esters of dibasic acids.** Z. H. Patel and H. E. Watson. *J. Indian Ind. Sci.* 16A, 55–67 (1933).—The velocity of alcoholysis by  $MeOH$  and  $EtOH$  of, resp. the di- $Et$  and di- $Me$  esters listed below is detd. at 30° by a dilatometric method, with an excess of alc. and  $HCl$  as catalyst, and by taking precautions to exclude  $H_2O$ . Except for the oxalates, the data support the assumption that, for a given sym. ester, the reaction of each terminal group is unimol., and occurs with  $d$  rate and vol. change equal to, and independent of, that of the other group, giving a unimol. velocity const. for the reaction as a whole. With the oxalates there is a slight effect of one terminal group on the other, OMe having a retarding influence relative to  $OEt$ . In the unsym. malate the reaction velocity of each group is unimol., but the 2 rates are no longer equal. The velocities are a little less than proportional to the  $HCl$  concn. in the range studied, about 0.03–0.11  $N$ . The esters studied

and the resp. velocity consts. in min.<sup>-1</sup> at 0.05 *N* HCl are as follows: di-Me oxalate 248, malonate 39.5, succinate 50.3, adipate 111, suberate 113, azelate (*b*<sub>28</sub> 175°) 114, sebacate 114; di-Et oxalate 762, malonate 142, succinate 212, adipate 442, tartrate 76.5, malate 554 ( $\alpha$  group) and 116 ( $\beta$  group). H. A. Beatty

**A new acetonesugar.** R. Weidenhagen. *Pharm. Monatsh.* 14, 171 (1933).<sup>2</sup> By the action of Ag<sub>2</sub>CO<sub>3</sub> or Ag<sub>2</sub>O on acetobromoglucose in dry acetone a new acetonesugar may be produced a bis(tetraacetylglucosyl) acetal of acetone, prismatic needles, m. 152.3°. H. M. B.

**The 2,4-dinitrophenylhydrazine reagent with carbonyl compounds.** C. Torres and S. Brosa. *Anales soc. españ. fis. quim.* 31, 649 (1933); cf. *C. A.* 27, 1590. The behavior of  $\alpha$ -hydroxycarbonyl compds., especially sugars, with 2,4-dinitrophenylhydrazine (I) was investigated. The utility of I in the detn. of solns. of MeCO and CH<sub>2</sub>O, of AcH from the oxidation of lactic acid, and the detn. of PhCH·CHClO in cinnamon essence, aq. exts. and tincture of cinnamon, was tested. E. M. S.

**The glycerolysis of sucrose.** H. Vogel. *Ber.* 66B, 1670 (1933); cf. *C. A.* 22, 1480; Berner, *C. A.* 27, 4780. In connection with the depolymerization of inulin with glycerol, expts. had also been made with sucrose in attempts to prep. in pure form the glycerol fructoside which had been obtained from inulin. Although a cryst. and absolutely homogeneous product was not obtained the results gave certain indications that a degradation of the sucrose had occurred. V. considers the intermediate formation of a fructose anhydride very probable. Five g. sucrose was heated 1.5 hrs. at 130° under 12 mm. with 30 g. anhyd. glycerol and the product was then freed from most of the glycerol in a high vacuum and thoroughly stirred with abs. alc. contg. 10% ether, which threw out a viscous sirup. From this sirup were obtained phenylglucosazone and glucose  $\beta$ -pentaacetate, while the alc.-ether soln. yielded a sirup (glycerol fructoside) which tasted bitter, evolved a very strong odor of acrolein when heated with KHSO<sub>4</sub>, did not reduce Fehling soln., showed in water  $[\alpha]_D^{20}$  26.14° (changed to 79.5° when boiled 0.5 hr. with dil. HCl) and slowly gave phenylglucosazone when boiled with aq. PhNHNH<sub>2</sub>.  $\alpha$ -Galactosan heated in the same way with glycerol gave a bitter sirupy product which did not reduce Fehling soln., and rhamnosan and arabinosan yielded similar products.  $\alpha$ -Glucosan heated 1 hr. at 120° with 10 parts anhyd. MeOH gave  $\alpha$ -Me glucoside and  $\alpha$ -galactosan yielded  $\alpha$ -Me galactoside. C. A. R.

**Lignin.** VI. Armin Hillmer. *Ber.* 66B, 1600 (1933); cf. *C. A.* 25, 4277. The interdependence of the ultra-violet absorption spectra and chem. constitution permits conclusions concerning the structure of lignin to be made from the comparison of the ultra violet absorption consts. of lignin and numerous aromatic substances. A series of ultra-violet color groups has been compiled, comprising families of substances with similar spectra. All spectra of the members of such groups can be distinguished from each other though their extinction values are of the same order of magnitude and the displacement of their max. apts. to a few  $m\mu$  at the most. From numerous quant. measurements of the absorption spectra of various lignins it has been shown that lignin belongs to the group related to pyrocatechol and ethyllignin from beech to the pyrogallol group. Lignin may have a basic unit made up of di- or trihydric, partially esterified phenols with a side chain of 3 C atoms contg. neither double linkage nor CO group in conjunction with the benzene ring. The % content of optically active material ( $X\%$ ) in an unknown substance can be estd. from the relation  $X\% = E' \cdot M/10e$  where  $e$  is the molar extinction coeff. of any member of the same ultra-violet color group and  $E'$ ,  $M$  are the extinction coeff. and mol. wt. of the unknown substance. It is known that the members of homologous series contg. a regularly occurring atom group with a characteristic spectrum show one and the same spectrum and that equimol. solns. show an increase in intensity corresponding to the no. of such recurring ab-

sorbing groups (*C. A.* 26, 4300). It is shown by the spectrochem. behavior of a series of gallic acid esters of polyhydric alcs. that this spectral additivity holds good for long chains in a polymer homologous series. Thus substances which are polymer homologs show the same spectrum as the simple fundamental unit and so since the ultra-violet absorption spectrum of alkali lignin from rye straw is that of the unit C<sub>10</sub>H<sub>12</sub>O<sub>4</sub> it becomes possible to show that lignin is practically entirely built up from its aromatic fundamental unit. From the formula given ( $E'$  for ash-free lignin from rye straw, 21,170;  $M$  for C<sub>10</sub>H<sub>12</sub>O<sub>4</sub>, 196 and  $e$  for eugenol, 4470)  $X = 93\%$ . This finding agrees with the investigations on purely chem. grounds into the constitution of lignin made by Freudenberg and his co-workers. C. R. Addinall

**Physical constants of cyclic hydrocarbons.** P. Martin Vivaldi. *Anales soc. españ. fis. quim.* 31, 645 (1933).

The sp. deviation of Dargmois (*C. A.* 15, 622), the parachor of Sugden (*C. A.* 19, 197) and the Raman spectra of ethyl-*l*-cyclopentene, ethyl-*l*-cyclohexene, ethylcyclopentane, and ethylcyclohexane were detd. The results agree with those obtained by others. E. M. S.

**Naphthenic acids and naphthenesulfonic acids. III. Chemistry, physics and physiology of naphthenic acids.** M. Naphthal. *Fettchem. Umschau* 40, 176 (1933); cf. *C. A.* 27, 5062. - A résumé including patent literature. P. Escher

**Some new hydroaromatic compounds of the cyclooctane series.** M. Godchet and Mlle. Cauquil. *Chimie & Industrie Special No.*, 1019 23 (June, 1933); cf. *C. A.* 22, 1335, 1960, 3147; 25, 3972. - Treatment of Me cycloheptanocarboxylate with MeMgI gives asym. dimethylhexamethylene glycol (isopropylcyclohexylpinacol) (I), *b*<sub>p</sub> 128.30°, m. 45°. Dehydration of I, either by H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> at 135-40° in the presence of H<sub>2</sub>O or by concd. H<sub>2</sub>SO<sub>4</sub> at 0°, gives: (1) mainly C<sub>10</sub>H<sub>16</sub>, *b*<sub>p</sub> 68°, *b*<sub>100</sub> 188.90°, *d*<sub>4</sub><sup>20</sup> 0.8868, *n*<sub>D</sub><sup>20</sup> 1.4946, mol. refraction 45.68 (calcd. 45.24), Nekrasov's const. (*C. A.* 23, 4380) 32.31; (2) a small amt. of mixed ketones probably contg. some 2,2-dimethylcyclooctanone. Reduction of  $\alpha$ -methylcyclooctanone: (1) by Pt black, gives  $\alpha$ -methylcyclooctanol A, *b*<sub>16</sub> 100.1°, *b*<sub>20</sub> 201.2°, *d*<sub>4</sub><sup>20</sup> 0.9400, *n*<sub>D</sub><sup>20</sup> 1.4750, mol. refraction 42.52 (calcd. 43.08), gives an acid phthalate m. 104°, and a phenylurethan m. 137°; (2) by abs. alc. and Na, gives  $\alpha$ -methylcyclooctanol B, *b*<sub>16</sub> 103.4°, *d*<sub>4</sub><sup>20</sup> 0.94304, *n*<sub>D</sub><sup>20</sup> 1.4808, mol. refraction 42.38 (calcd. 43.08), gives an acid phthalate m. 119.20°, and a phenylurethan m. 151°. It has not yet been detd. which of the 2 is the *cis*- and which the *trans*-isomer. Reduction of  $\alpha,\alpha$ -dimethylcyclooctanone in abs. alc. by Na gives  $\alpha,\alpha$ -dimethylcyclooctanol, *b*<sub>6</sub> 91.2°, *b*<sub>24</sub> 219.20°, *d*<sub>4</sub><sup>20</sup> 0.9540, *n*<sub>D</sub><sup>20</sup> 1.4798, mol. refraction 47.50 (calcd. 47.60), gives an acid phthalate m. 110.3°, and a phenylurethan m. 147°. Cyclooctylcarboxylic acid, prepd. by treating the Mg deriv. of cyclooctyl bromide with CO<sub>2</sub> gas, *b*<sub>19</sub> 150°, *d*<sub>4</sub><sup>20</sup> 0.9931, *n*<sub>D</sub><sup>20</sup> 1.4779, mol. refraction 45.03 (calcd. 45.20); the acid chloride, *b*<sub>19</sub> 110°, with NH<sub>3</sub> aq. gives cyclooctylcarboxamide, m. 191°. A. P.-C.

**Decomposition of phenyl dichloriodide. IX. Molecular weight and electrical conductivity of its solutions.**

**X. Structure of a typical salt representing dichloriodides, trichloriodide, and phosphorus pentachloride.** Enrique V. Zappi and Sta. Juanita Cortelezzi. *Anales asoc. quim. Argentina* 21, 71 99 (1933); cf. *C. A.* 27, 2139. PhICl<sub>2</sub> solns. in PhN(O)<sub>3</sub> or POCl<sub>3</sub> show low cryoscopic mol. wt., indicating disson. The elec. cond. of solns. in POCl<sub>3</sub>, AsCl<sub>3</sub>, or CHCl<sub>3</sub> is zero. Solns. in pyridine or PhN(O)<sub>3</sub> have low elec. conductivities, 8.3 and 0.5, resp., which are in accord with those found by others for substances whose structures resemble that of PhICl<sub>2</sub>, e. g., pyridine chloriodide, ICl<sub>3</sub>, and PCl<sub>3</sub>, indicating disson. in i.-p. detns. is not of ionic nature, but mol., e. g., PhICl<sub>2</sub> · Cl<sub>2</sub> + PhI. Iodonium structures lack exptl. support. The low elec. cond. can be explained by formation of complexes with the solvent, comprising sluggish ions of high mol. wt. A stable PhICl<sub>2</sub> was prepd. The soly. of PhICl<sub>2</sub> in POCl<sub>3</sub> was detd. E. M. S.

**Dinitropolyhalogen derivatives of benzene.** Shiam Sundar Joshi and Shrirang M. Sane. *J. Indian Chem. Soc.* **10**, 459-63 (1933).—4,2,6-Br(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>2</sub>Cl (I), treated in boiling EtOH with a current of NH<sub>3</sub>, produced 4,2,6-Br(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>2</sub>NH<sub>2</sub>. I, treated similarly with the corresponding amine, gave the following: 4-bromo-2,6-dinitrodiphenylamine; 4-bromo-2,6-dinitrodiphenylamine, m. 119°; 4-bromo-2,6-dinitrophenylpiperidine, m. 110°; bis(bromodinitrophenyl)-p-phenylenediamine, m. above 300°; 3-bromo-5-nitrophenoxazine, m. 179°; 2-phenyl-5-bromo-7-nitropseudoaziminobenzene, m. 179°. Similarly, 4,2,6-I(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>2</sub>Cl gave 4-iodo-2,6-dinitroaniline, m. 175°; 4-iodo-2,6-dinitrodiphenylamine, m. 135°; 4-iodo-2,6-dinitrophenylpiperidine, m. 90°; 3-iodo-5-nitrophenoxazine, m. 210°; 2-phenyl-5-iodo-7-nitropseudoaziminobenzene, m. 209°. 2,4,6-Br(O<sub>2</sub>N)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>Cl likewise produced 2-bromo-4,6-dinitrophenylpiperidine, m. 127°; 2-phenyl-7-bromo-5-nitropseudoaziminobenzene, m. 174°. 2,4,6-I(O<sub>2</sub>N)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>Cl similarly gave 2-iodo-4,6-dinitroaniline, m. 158°; 2-iodo-4,6-dinitrodiphenylamine, m. 144°; 2-iodo-4,6-dinitrodiphenylamine, m. 122°; bis(iododinitrophenyl)-p-phenylenediamine, m. above 300°; 2-phenyl-7-iodo-5-nitropseudoaziminobenzene, m. 192°; 3,5-dinitrophenoxazine, m. 214-15°. Julius White

**The kinetics of transformation of haloalkylamines into heterocyclic compounds. V. The influence of phenyl groups on ring closure and breaking.** H. Freundlich and G. Salomon. *Z. physik. Chem.* **A166**, 161-78 (1933); cf. *C. A.* **20**, 3686. The following reaction was studied in acid and basic soln. at various temps.: PhCHCl-NaOH

**New and improved methods for the synthesis of pharmacologically important amines. VII. Synthesis of secondary and tertiary amines by the hydrogenation of nitriles.** Karl Kindler and Fritz Hesse. *Arch. Pharm.* **271**, 439-45 (1933); cf. *C. A.* **27**, 278. In the reduction of nitriles there are formed, in addn. to primary, the corresponding secondary and tertiary amines, due apparently to a complication in the procedure, e. g., inter-

mediate appearance of an aldimine:  $\text{RCN} \xrightarrow{+2\text{H}} \text{RCH:NH} \xrightarrow{+2\text{H}} \text{RCH}_2\text{NH}_2$ . The aldimine (I) forms, either directly or after preliminary transition to an aldehyde (II), with primary amine already present, compds., the reduction of which leads to a secondary amine (scheme A). This procedure thereupon undergoes repetition, with formation of a tertiary amine (scheme B).

Scheme A:

Scheme B:

An analysis of these schemes reveals the possibility of preparing any desired secondary or tertiary amine from

nitriles. To this end there is added, at the initial stage of the catalytic hydrogenation of a nitrile  $\text{RCN}$ , a primary or secondary amine  $\text{R}'\text{NH}_2$  or  $\text{R}'\text{NHR}'$ . These amines thereupon react with the intermediate products, in accordance with the scheme A or B, resp., to yield the compd.  $\text{RCH}_2\text{NHR}'$  or  $\text{RCH}_2\text{NR}'^2$ . As examples of the new procedure, syntheses of epinine, hordenine and hydroxyhordenine are described. W. O. E.

**$\beta$ -Phenylhydroxylamine.** Eugen Muller and Erich Lindemann. *Angew. Chem.* **46**, 681-5 (1933).—The thermal decompn. of  $\beta$ -phenylhydroxylamine,  $\text{C}_6\text{H}_5\text{NHOH}$  (I), was found to be a dehydration reaction. The first product formed is azoxybenzene which then changes to azobenzene. In the normal reaction the  $\text{H}_2$  does not go to form azobenzene but is used mainly for the formation of aniline. However, if azoxybenzene is initially present then at higher concns. it takes up the  $\text{H}_2$  so that aniline disappears and azobenzene is formed. The reaction has the character of a chain reaction, where the azoxybenzene formed is reduced by I, forming PhNO which in turn forms azoxybenzene. The PhNO acts as the chain carrier. Some derivs. of I were investigated also, and it was found that the Me ether of the mono-Bz compd. forms largely  $\text{BzNHPh}$  and  $\text{CH}_3\text{O}$  and that the di-Bz compd. remained completely unchanged under the exptl. conditions. The exptl. procedures and results are reported in detail, an anal. method for the detn. of I is given, also dehydration expts. with Pd black, and the preps. of an alkyl ether of the mono-Bz compd. and the mono-Ac compd. of I are described. K. K.

**The constitutional formula of laccol.** Gabriel Bertrand and Georges Brooks. *Chimie & Industrie Special No.*, 1085-6 (June, 1933).—See *C. A.* **26**, 5558. A. P.-C.

**Catalytic oxidations. II. The oxidation of benzaldehyde.** Karl Meyer. *J. Biol. Chem.* **103**, 25-37 (1933); cf. *C. A.* **23**, 1561.— $\text{BzH}$ , purified by distn. and crystn., does not oxidize in  $\text{C}_6\text{H}_6$  but absorbs  $\text{O}_2$  very readily without an induction period in the presence of very small amts. of Fe. If purified by distn. alone, it is not immediately activated by Fe because of the presence of impurities which inhibit its catalytic oxidation. Pyridine-hemochromogen is a more effective catalyst than  $\text{Fe}^{+++}$  which in turn is more effective than  $\text{Fe}^{++}$ . PhOH inhibits the catalytic action of 10 times its equiv. of Fe and the inhibition is influenced by the order in which the materials are added, being much greater if the PhOH is added first. In acid soln.  $\text{BzO}_2\text{H}$  decomp. immediately either in the presence or absence of  $\text{BzH}$  but with  $\text{BzH}$  in non-aq. soln. it is stable even in the presence of hemin.

**III. The oxidation of pyruvic acid.** *Ibid.* 39-49. Only the enolic form of pyruvic acid is oxidized by hemin and photosensitizers, and the main oxidation product is  $(\text{CO}_2)_2$ . The speed of the reaction is proportional to the concn. of the acid and to the log of the eosin concn., other factors remaining const. The reaction is also dependent upon the nature of the fluorescent dye used. PhOH does not inhibit the reaction. A. P. Lothrop

**p-Azoxybiphenyl and p-azobiphenyl.** D. Vorländer. *Ber.* **66B**, 1666-7 (1933). All aromatic azoxy compds. are much more strongly cryst.-liquid (c.-l.) than the corresponding azo compds. but azobiphenyl (I) and azoxybiphenyl (II) were both described (*C. A.* **20**, 584) as having but 1 m. p. and being monotropically cryst.-liquid (m. c.-l.). Janecke, however, had earlier reported that II has 2 m. ps. (262° and 208°) and is enantiotropically cryst.-liquid (c. c.-l.). In view of a possible isomerism, I and II have been prepd. by various methods. I, prepd. (1) by reduction of  $p\text{-O}_2\text{NC}_6\text{H}_4\text{Ph}$  with Zn dust and boiling aq. alc. KOH to the hydrazo compd. and oxidation of the latter in alc. suspension with air or  $\text{FeCl}_3$ , or (2) from diazotized  $p\text{-PhC}_6\text{H}_4\text{NH}_2$  with  $\text{NH}_3\text{-Cu}_2\text{O}$ , crystallizes from AcOH or benzene in orange or brownish yellow leaflets sintering 254°, m. 256° (cor.), gives a violet color with concd.  $\text{H}_2\text{SO}_4$ ; it is m. c.-l., or e. c.-l. with a very small range of existence (about 1°). II, prepd. (1) from  $p\text{-O}_2\text{NC}_6\text{H}_4\text{Ph}$  and aq. alc. NaOH, followed by treatment with concd.  $\text{HNO}_3$  or AcOH-

$H_2O_2$ , (2) from  $O_2NC_6H_4Ph$  and Na in anhyd. MeOH, or (3) from  $HO_2NC_6H_4Ph$  heated or allowed to stand in moist soln., seps. in yellow c. c-l. crystals, m. 259-60° and 215-16° (cor.) (sintering at 211°), gives a brown-red color with concd.  $H_2SO_4$ . The sintering point is probably the transition point to the initially viscous cryst. liquid which on heating becomes more fluid and liquefies, as manifested by the 2nd m. p.

C. A. R.

**New and improved methods for the synthesis of pharmacologically important carboxylic acids. I. Synthesis of arylacetic acids from aromatic aldehydes, and of arylpropionic acids from aromatic carboxylic acids.** Karl Kindler and Wilhelm Peschke. *Arch. Pharm.* 271, 431-9 (1933). In expts. calcd. to develop certain relationships between chem. constitution and pharmacol. action, it is necessary to consider reactivity values. Based on this knowledge, Kindler has attempted to discover the laws appertaining thereto. For this purpose were required numerous carboxylic acids, prepd. either by the aid of new or improved methods. These procedures are described in the present and subsequent studies, the first 3 of which have to do with the prepn. of arylacetic and  $\beta$ -arylpropionic acids. Such acids are for various reasons important, notably because they far exceed the corresponding aromatic acids in bactericidal behavior. Furthermore, the amides and thioamides of arylacetic acids on reduction, and the amides of arylpropionic acids with  $KClO$ , yield smoothly pharmacologically important  $\beta$ - $\alpha$ -thylamines. Finally, the amides, resulting from the action of the arylthylamines on arylacetic acids, lead readily to  $\alpha$ -benzylisoquinolines, several representatives of which class, such as papaverine, cupaverine and perparine, already find therapeutic application. A noted improvement in the procedure hitherto followed in prepg. arylpropionic esters is indicated in the following:

$ArCH_2CH_2CO_2Et \rightarrow ArCH_2CH_2CO_2Et$ , in that one operation is eliminated. The utility of the new or improved procedures is illustrated in the prepn. of homoveratric acid, homoaconic acid, homopiperonic acid, phenylpropionic (resp. derivs. thereof) acid. W. O. F.

**Chemistry of isochavibetol. III. Action of Grignard's reagent on ethers of isochavibetol.** 2. Nenokichi Hirao. *J. Chem. Soc. Japan* 54, 991-5 (1933), cf. C. A. 27, 276-7. A new fact found in this expt. is that 3,4-RO-(MeO) $C_6H_3CH_2CHMe$  (I) give 3,4-HO-(MeO) $C_6H_3CH_2CHMe$  by the action of  $RMgX$  ( $MeMgI$  gives the best result although  $EtMgBr$  can be used), where R =  $CHMe_2$  (II),  $CH_2CH_2CH_3$ ,  $CH_2Ph$  or cyclohexyl (III). I give new acids, 3,4-RO-(MeO) $C_6H_3CO_2H$  (IV) when oxidized by  $KMnO_4$ . The m. p. of IV when R is II 135°, iso-Bu 161-2°, III 161-5°. K. Kitsuta.

**Action of potassium cyanide on meconin.** V. M. Rodionov, S. I. Kanevskaya and A. B. Davankov. *Ber.* 66B, 1623-7 (1933); cf. Bowman, *Ber.* 20, 890 (1887). B.'s observation that meconin does not add KCN to form  $(MeO)_2C_6H_3(CO_2K)CH_2CN$  has been confirmed. The KCN merely acts as a demethylating agent, giving MeCN and chiefly (45-70%) B.'s normeconin Me ether (I), m. 124-5°, with a little of an isomer (II), m. 86-8°. That I is 3-hydroxy-4-methoxyphthalide was established by ethylating it with  $p-MeC_6H_4SO_3Et$  to the Et ether, m. 68-9°, and oxidizing the latter with  $KMnO_4$  to 3,4,1,2- $C_6H_3(OEt)(OMe)(CO_2H)$ , m. 174-5° (anhydride, m. 105°, shows blue violet fluorescence in alc.; N-ethylamide, m. 83-4°). Both I and II give meconin in excellent yield on methylation (best with  $p-MeC_6H_4SO_3Me$ ); II is therefore 1-hydroxy-3-methoxyphthalide. C. A. R.

**Terpenes, sesquiterpenes and their related compounds. III. The molecular depression of the freezing point of camphene.** So Uchida and K. Shimoyama. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 725-7 (1933); cf. C. A. 27, 4989. The true mol. depressions of the f. p. of camphene in dil. solns. of  $C_{10}H_{16}$  and  $Ph$  were detd. At infinite diln. the mol. depression is  $K_b = 36.31$

and 38.85 for  $C_{10}H_{16}$  and  $Ph$ , resp., while the calcd. heats of fusion are 5.76 and 5.39 cal./g., resp. IV. **Fusion diagrams of the systems camphene-naphthalene and camphene biphenyl.** *Ibid.* 528-9.—The fusion diagrams and exptl. data are presented. K. K.

**Preparation of nitrosopinene.** G. Vitte. *Bull. inst. pin* 1933, 216.—The method described by Wallach and Lorentz (*Ann.* 268, 197) lacks precision. The following technic has been found to be quicker and to give a higher yield. To 300 cc. 95% alc. in a 1-l. flask gradually add 7 g. Na; when reaction is complete add 50 g. pinene nitroschloride; connect to a reflux condenser; place in a boiling water bath for 15 min., regulating the rate of boiling by adjusting the degree of immersion of the flask; filter, pour the filtrate gradually with stirring into 4 l.  $H_2O$  + 200 cc. AcOH, let stand a few hrs., filter, dry, wash with petr. ether and dry; yield 50% of theoretical; m. p. 132°.

A. Papincau-Couture

**Occurrence of  $\pi$ -hydroxy derivatives in camphorol.** Yasuhiko Asahima and Morizo Ishidate. *Ber.* 66B, 1673-7 (1933). Work with larger amts. of material has shown that the supposed labile 5-ketocamphor, m. 210°, obtained by energetic oxidation of 5-hydroxycamphor (C. A. 25, 2990), is in fact a quite complicated mixt. (I) of structural isomers and the "1,5,5-trimethylcyclopentane-2,4-dioneacetic acid" is not a homogeneous substance. From the acid products of the autooxidation of I there have now been isolated 2 sharply defined isomers  $C_{10}H_{14}O_4$ , which are satd monoketocarboxylic acids and can be sepd. by reason of their different solubilities in water. The more difficultly sol. A isomer (II), m. 249-50°,  $[\alpha]_D^{25}$  3.17° in abs. alc. (phenylhydrazine, yellowish, m. 205° (decompn.), semicarbazone, m. 255° (decompn.)), is probably Wedekind and Stusser's isoketopinic acid (C. A. 18, 67), and the B isomer (III), m. 272°,  $[\alpha]_D^{25}$  67.2° in abs. alc. (semicarbazone, m. 204-5° and, after repeated fusions, 215-6°), is presumably Hasselstrom's ketodihydroteresanilic acid (2-keto- $\pi$ -apocamphane-7-carboxylic acid) (C. A. 25, 1823). Wolff reduction of II gives 1- $\pi$ -apocamphane-7-carboxylic acid, m. 231°,  $[\alpha]_D^{25}$  18.16° (abs. alc.), and III gives the d-antipode, m. 231°,  $[\alpha]_D^{25}$  18.0° (abs. alc.). Further oxidation of II with  $KMnO_4$  or concd.  $HNO_3$  yields trans-d-camphotricarboxylic acid, m. 197°,  $[\alpha]_D^{25}$  38.8° (abs. alc.),  $[\alpha]_D^{25}$  15.0° (water) (anhydride, m. 251°). Although the cis-d-isomer has not yet been isolated from the oxidation products of III, it is assumed, from the formation of the stereoisomeric  $\pi$ -apocamphane-7-carboxylic acids, that the CO $_2H$  group in III is in the cis position. Camphorol therefore contains, in addn. to 3- and 5-hydroxycamphor, at least 2  $\pi$ -hydroxycamphors which, on mild oxidation of camphorol, are first converted into an aldehyde mixt. which is then rapidly autooxidized to II and III. In fact, I with  $NaHSO_3$  yields a substance (mono-semicarbazone,  $C_{10}H_{17}O_3N$ , m. 202° (decompn.); di-semicarbazone, becomes discolored about 300°, decomp. around 360°), which in the free state rapidly changes into a mixt. of II and III but does not reduce Fehling soln. or  $NH_3 \cdot AgNO_3$ . C. A. R.

**Highly arylated benzene derivatives. I.\*** W. Dillthey, W. Schommer and O. Trosken. *Ber.* 66B, 1627-8 (1933), cf. C. A. 27, 2676. The deeply colored ketones of the cyclopentadienone series readily add maleic anhydride tetraphenylcyclopentadienone, e. g., giving endo-carboxyltetraphenylidihydrophthalic anhydride (I)  $CPh CPh CH CO$

by alkalis to the dicarboxylic acid. On heating, I loses  $CO$  and yields tetraphenylidihydrophthalic anhydride (II), m. 243° (the m. p. depends greatly on the method of heating and may be found higher than 250°), which on higher heating (about 200°—so given in original Abstr.) with or without dehydrating agents splits off  $H$  and gives tetraphenylphthalic anhydride (III), m. 286° (depending

on method of heating). Instead of maleic anhydride all possible ethylene or acetylene compds. can be used, according as it is desired to obtain analogs of II or of III. Thus,  $C_2H_2$  gives 1,2,3,4-tetraphenylbenzene, m. 190  $1^\circ$ , also obtained by distn. of III with soda-lime, and PhC CII gives  $C_6HPh$ , m. 246  $7^\circ$ . Tolun (as also stilbene) yields a very difficultly sol. cryst. substance, m. 421  $2^\circ$ , having the compn. of  $C_6Ph_2$  but which is different from the compd. (m. 260 $^\circ$ ) described by Durand and Hsun (C. A. 25, 1501). PhC CCO $_2$ H yields pentaphenylbenzoic acid, m. 345 $^\circ$ ; the nitrile, from PhC CCN, m. 271  $2^\circ$ ; the aldehyde, from PhC CCHO, is cryst. C. A. R.

**Optical activity in the case of triphenylmethane derivatives.** I. Lischitz. Z. wiss. Phot. 32, 131-41 (1933).—The proof of the existence of optically active carbonium salts (halochromes) does not allow a decision between the benzoid and the quinoid formula. Only investigations of the rotation, or better the rotator dispersion, of the colorless and colored triphenylmethane derivs. might render this possible. The existence of optically active halochromes is impossible according to the theories of Diltz and Hantzsch, as long as it is not assumed that compds. of the type C<sup>1</sup>abd can be optically active. This assumption is to be characterized as at least improbable. The views advanced by L. would, on the other hand, allow the existence of active halochromic compds. to be immediately explained. The question of the existence of such compds. must be tested by further investigation. F. R. Bullock

**Preparation of methyl green.** A. G. Pukirev. Khim. farm. Prom. 1933, 120 2. Crystal violet base (50 g.), 27.5 g. of  $p$ -MeC $_6$ H $_4$ SO $_3$ Me and 250 cc. of Me $_2$ CO is boiled for 8 hrs. The ppt. on cooling is dissolved in 10% HCl and treated with 20 g. of ZnCl $_2$ , 5 g. of Zn(OAc) $_2$  and 200 g. of NaCl and the pptd. needles are filtered, washed with 5% NaCl and dried at 60 $^\circ$ . The yield of methyl green is 95%. Fifty g. of methyl violet base and 100 g. of the  $p$ -toluenesulfomethylate is fused with mixing at 125-30 $^\circ$ . The unreacted methyl violet base is pptd. with NH $_4$ OH and from the filtrate methyl green is salted out as above. The yield is 35-55%. L. N.

**The autoxidation of tetralin (tetrahydronaphthalene).** I. Piatti. Angew. Chem. 46, 638-9 (1933).—Absorption of atm. O $_2$ , followed by heating, increases the d., b.-p. and viscosity of tetralin. Higher-boiling acids which attack metals are formed during the process. The use of alkali in titration is a measure of the degree of oxidation. Distn. and viscosity-temp. curves are presented. Ten references. Karl Kammermeyer

**The naphthylamines in coal tar.** O. Kruber. Ber. 66B, 1653-4 (1933); cf. C. A. 26, 5936. The coal-tar oils b. around 300 $^\circ$  contain about 6% of basic constituents consisting chiefly of quinoline and isoquinoline derivs. of unknown structure and a smaller quantity of primary amines. As representatives of the latter have now been isolated the 2 naphthylamines. The crude tar bases, b. 290  $6^\circ$ , contained 8-10% of the 2 amines, as estd. from acetylation expts. C. A. R.

**Condensation of ethyl propylacetoacetate with aromatic amines II.** G. V. Jadhav. J. Indian Chem. Soc. 10, 391-4 (1933); cf. C. A. 26, 2969. The treatment of MeCOCH $_2$ CH $_2$ CO $_2$ Et with  $\alpha$ -C $_6$ H $_4$ NH $_2$  gave di- $\alpha$ -naphthylcarbamide, m. 296 $^\circ$ . Similarly prepd. were the following: di- $\beta$ -naphthylcarbamide, m. 310 $^\circ$ ; propylacetoacet- $\beta$ -naphthylamide, m. 115  $6^\circ$ ; bis( $\alpha$ -ethoxyphenyl)carbamide, m. 220  $1^\circ$ ; propylacetoacet- $\alpha$ -phenetide, m. 90  $1^\circ$ ; bis( $p$ -hydroxyphenyl)carbamide, m. 280 $^\circ$  (decompn.); propylacetoacet- $p$ -hydroxyphenylamide, m. 95  $6^\circ$ ; propylacetoacet- $m$ -hydroxyphenylamide, m. 223  $1^\circ$ , 1c deriv. 165 $^\circ$ ; bis( $\alpha$ -chlorophenyl)carbamide, m. 235  $6^\circ$ ; propylacetoacet- $\alpha$ -chloroanilide, m. 83-4 $^\circ$ ; bis- $m$ -chlorophenylcarbamide, m. 245  $6^\circ$ ; propylacetoacet- $m$ -dichloroanilide, m. 88-9 $^\circ$ ; bis( $p$ -chlorophenyl)carbamide, m. 289-90 $^\circ$ ; propylacetoacet- $p$ -chloroanilide, m. 123-4 $^\circ$ ; bis( $m$ -nitrophenyl)carbamide, m. 241-2 $^\circ$ ; propylacetoacet- $m$ -nitroanilide, m. 95  $6^\circ$ ; bis( $p$ -nitro-

phenyl)carbamide, m. 310 $^\circ$ ; propylacetoacet- $p$ -nitroanilide, m. 118  $9^\circ$ . Julius White

**Course of the alkylation of enolates.** Gustav Vapags. Ber. 66B, 1678-81 (1933). Adickes, v. Hessling and v. Mullenheim (C. A. 27, 3700) believe that in the action of alkyl halides on enolates C-alkyl derivs. are formed directly and not through intermediate O-alkyl ethers. In the course of work on alkylbiindones which will be described in detail elsewhere, V. has made some observations, however, which confirm the intermediate formation of O-alkyl ethers. When carefully purified, completely isobiindone-free biindone is boiled in alc. with excess of K $_2$ CO $_3$ , no isobiindone is formed, but if MeI or other alkyl halide is added, C-alkylbiindone and isobiindone are produced. The formation of the latter can be explained by the primary formation of O-alkylbiindone which adds water at its conjugated double bond (at the 3,6- or 1,6-positions) and then splits off alc. at position 6, with formation of K isobiindone. This salt, being almost insol. in the soln. of the K biindone, is pptd. and thus protected from reconversion into biindone. This view is further confirmed by the fact that the pure Me or Et ether of biindone gives isobiindone in abundance when boiled with K $_2$ CO $_3$ . C. A. R.

**Synthesis of hydrocarbons with high molecular weight.** M. Lerer. Ann. combustibles liquides 8, 681-733 (1933).

The action of alkyl halides upon Na addn. products of anthracene leads to good yields of 9,10-dihydro-9,10-dialkylanthracene and the true anthracenic deriv., the dialkylanthracene, is always formed in small quantities. The reaction is independent of the halogen; chlorides, bromides and iodides can be used with like success. Also the length of the chain of the halogen deriv. does not seem to exert any influence. The solvent which serves as medium influences the speed of formation of the Na anthracene addn. product only. This formation is accomplished very easily in ether and liquid NH $_3$  while it takes place very slowly in toluene and xylene. The alkylation reaction of aromatic hydrocarbons by the intermediate way of their Na compds. is not limited to anthracene only. The Na deriv. of C $_{10}$ H $_8$  prepd. in liquid NH $_3$  gives on treatment with halogen a 1,2,3,4-tetrahydro-1,4-dialkyl-naphthalene and a more condensed deriv. of (C $_{10}$ H $_7$ ) $_2$ . The Na addn. compds. of aromatic hydrocarbons can also be used for other than alkylation syntheses, e. g., the action of BzOEt upon the Na deriv. of 9,10-dihydroanthracene results in the formation of mono- and di-benzoyldihydroanthracene. With octyl alc. as starting product a series of liquid hydrocarbons with side chains and higher mol. wt. was obtained. By dehydration of di- and tricaprylic alc. the unsatd. hydrocarbons dicaprylene C $_{24}$ H $_{42}$  and tricaprylene C $_{26}$ H $_{44}$  were obtained. Na treatment in a toluene medium results in the formation of the satd. hydrocarbons C $_{26}$ H $_{54}$  and C $_{28}$ H $_{58}$  from dicaprylic iodide and tricaprylic bromide, resp. By the action upon Me palmitate of the Grignard reagent prepd. from bromooctane, the unsatd. hydrocarbon C $_{18}$ H $_{34}$  was obtained through the intermediary compd. pentadecyldioctylcarbmol. A series of oxidation tests was carried out to det. the constitution of the unsatd. hydrocarbons. It was found that the use of 0.2 N KMnO $_4$  in presence of H $_2$ PO $_4$  permitted the limitation of oxidation to the double bond with 3-C chain olefins only. For hydrocarbons with side chains the reaction becomes more complex, the tertiary C atoms being attacked simultaneously with the double bond. K. K.

**$\alpha$ -Dihalogenated benzantrones and their transformation by sodium sulfide.** Kurt Brass and Charles Lauer. Chimie & industrie Special No., 876-82 (June, 1933).

From the behavior of halogenated benzanthranyl sulfides, which are described in detail, it is concluded that the C atoms to which are attached the S atoms and those to which are attached the halogens are not situated in the same plane, and consequently their structure is not favorable to the formation of thianthrene nuclei.

**Sandmeyer's indigo synthesis.** Rin-nosuke Shibata,

Minoru Okuyama and Katsuo Okamura. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 569 71(1933).—The action of concd.  $H_2SO_4$  upon oxaldiphenylamidinethioamide is given. When the thioamide was heated with concd.  $H_2SO_4$  at 90–95° for 2.5 hrs., followed by 1 hr. at 105–110°,  $\beta$ -isatinilide was the main product, while on heating at 50° both  $\alpha$ - and  $\beta$ -isatinilide were obtained. Both compds. were also obtained on heating for 1 hr. only at 90°.

Karl Kammermeyer

**Isatin from indigo.** P. N. Rabinovich and V. K. Dzirkal. *Khim. Farm. Prom.* 1933, 190 2. Powd. indigo (5 moles) is stirred into 8 kg. of ice and 1.3 l. of  $H_2SO_4$  and 1.3 kg. of  $Na_2Cr_2O_7$  in 2 l. of  $H_2O$  is slowly added (temp. 1–2°). After 0.5 hr. the temp. is raised to 50–60°, the mixt. cooled and isatin filtered out. Unreacted indigo is removed by dissolving the ppt. in 4 l. of 10%  $NaOH$  at 80°, filtering, acidifying at 90° with  $HCl$ , cooling and filtering again. For complete sepn. of 3 indigo the purification is repeated. Yield, 75–80%.

L. Nasarevich

**Tris(arylamino)ethylenes. III. The reaction products of sulfur and tris(phenylamino)ethylene.** (Supplement.)

Rin-nosuke Shibata, Minoru Okuyama, Nakaba Kojima and Tetsumosuke Nishi. *J. Soc. Chem. Ind., Japan* 36, Suppl. binding 511 14(1933), cf. *Ibid.* 32, 282 4(1929).

Exptl. results on melts of tris(phenylamino)ethylene and S at 150° showed the existence of 5 compds.: (1) bis(phenylamino)ethylene ( $C_{14}H_{14}N_2$ ), (2) tris(phenylamino)mercaptioethylene ( $C_{20}H_{18}N_3S$ ), (3) dithiooxanilide ( $C_{14}H_{12}N_2S_2$ ), (4) thiooxanilide ( $C_{14}H_{12}N_2SO$ ), (5) oxanilide ( $C_{14}H_{12}N_2O_2$ ). Compds. (4) and (5) are only secondary reaction products. The expts. are described in detail. **IV. The action of sulfur on tris(o-tolylamino)ethylene.** *Ibid.* 511 17.—Fusion at 130–5° resulted in the formation of the following compds.: (1) dithiooxalo(o-toluide),  $C_{18}H_{16}N_2S_2$ , (2) tris(o-tolylamino)mercaptioethylene,  $C_{22}H_{20}N_3S$ , and (3) bis(o-tolylamino)ethylene,  $C_{18}H_{18}N_2$ . Exptl. procedure and results are presented. **V. Action of sulfur upon tris(p-tolylamino)ethylene.** Rin-nosuke Shibata and Tetsumosuke Nishi. *Ibid.* 538 40. Heating 5 parts of the base with 1 part of S at 140° for 60 min. resulted in an orange-red melt which permitted isolation of the following compds.: (1) bis(p-tolylamino)ethylene,  $C_{18}H_{18}N_2$ , (2) tris(p-tolylamino)mercaptioethylene,  $C_{22}H_{20}N_3S$ , and (3) dithiooxalo-p-toluide,  $C_{18}H_{16}N_2S_2$ . Exptl. details are presented.

Karl Kammermeyer

**Constitution of the antipyridines. Action of sodium on 1,2-diphenyl-3-methylpyrazolone.** Albrecht Heymons and Werner Rohland. *Ber.* 66B, 1654 61(1933).

Although antipyrine (I) is quite stable toward Na and boiling alc., with Na and  $CO_2$  in hot PhMe the ring is opened with formation of  $PhNHCOCH:CMcNHMe$  (Knorr, *Ber.* 25, 768(1892)). In attempts to gain light on the mechanism of the reaction by a study of the by-products, which are formed to the extent of about 30%, considerable difficulties were encountered because of unfavorable soly. relationships and attention was directed to 1,2-diphenyl-3-methyl-5-pyrazolone (II) (the "oxymethylphenylquinizine" obtained from  $AcCH_3CO_2Et$  and  $PhNHNHPh$ ), which is stable toward acids and alkalis and forms a 4-NO deriv. reduced to the corresponding  $NH_2$  deriv. and undergoing with  $PhNHNH_2$  the cleavage characteristic of nitrosoantipyridines. With Na and  $CO_2$  in PhMe II gives, besides  $PhNH_2$  and  $AcCH_3CONHPh$  (the hydrolysis products of the expected  $PhNHCOCH:CMcNHPh$ ), a small amt. of an acid  $C_{17}H_{16}O_2N_2$  (III) which on heating readily loses  $CO$  and gives a base  $C_{16}H_{16}ON_2$  (IV), quite stable toward acids and alkalis and contg. 2 tertiary N atoms. IV can therefore be only 1,2-diphenyl-3-methyl-5-pyrazolidone and III the corresponding carboxylic acid. That the  $CO_2H$  group in III is not in the 4-position is indicated by the fact that the enolate obtained from IV cannot be converted into III. Furthermore, II reacts with Na in the absence of  $CO_2$ , taking up 2 atoms without evolution of  $H_2$ ; when the soln. of the resulting di-Na compd. is treated with  $Ac_2O$  and

subsequently with  $CO_2$ , only 1 Na atom reacts, giving an Ac deriv. (V) of III. As V is stable toward acids and alkalis it must be a C-Ac deriv., and since on decarboxylation it gives the same base  $C_{15}H_{14}O_2N_2$  (VI) as is obtained from the enolate of IV with  $Ac_2O$ , the  $Ac_2O$  in the formation of V, can have reacted only with a Na atom attached to the O of the  $C:O$  group, and the Na atoms in the di-Na compd. must be in the 3- and 5-positions. The formation of III is greatly favored if the II is heated with Na a long time before being treated with  $CO_2$ ; if the 2 are allowed to react simultaneously on II, ring cleavage occurs almost exclusively and only traces of III are formed. The di-Na compd. and III are therefore both probably formed secondarily from a common intermediate product. The primary product of the reaction of Na can readily be derived only from the betaine form of II and would then have the structure  $\begin{array}{c} CH \\ || \\ NaOC \\ | \\ NPh \\ | \\ NPhNa \end{array}$ .

The tendency of such a compd. to undergo ring cleavage between the N atoms on treatment with  $CO_2$  and also the tendency to rearrange into a 3,5-di Na compd. (with change of the N from the 5- to the 3-valent stage) is readily understandable. So also, when the di-Na compd., prepd. at the lowest possible temp., is at once treated with  $Ac_2O$ , there is obtained, in addn. to V, a compd.  $C_{18}H_{16}O_2N_2$  (VII) which on acid hydrolysis under even mild conditions gives  $AcCH_3CONHPh$ ,  $AcOH$  and  $PhNH_2$  and must therefore be  $\beta$ -anilinoaceton-N-acetylanilide, a structure confirmed by the rearrangement, under the influence of traces of acid, of VII into  $\beta$ -(acetylanilino)-crotonanilide (VIII) which is hydrogenated to  $MeCH(NAcPh)CH_2CONHPh$  and is hydrolyzed to  $AcNHPh$ ,  $PhNH_2$  and  $AcCH_3CONHPh$ . II, obtained in 63% yield,  $b_p$  250–60°, m. 130°; picrate, yellow, m. 138°; 4-Br deriv., m. 145°; 4-NO deriv. (yield, 80%), green amorphous ppt. quickly decomg. in the reaction soln.; 4-amino deriv., m. 165° (yield, 64%, based on II). 1,2-Diphenyl-3-methylpyrazolidone-3-carboxylic acid (III), dc compds. 122° (yield, 5%, increased to 39% if II is heated 4 hrs. with 5 mols. Na before it is treated with  $CO_2$ ); Me ester, m. 130°. IV, m. 126°. 4-Ac deriv. (VI) of IV, m. 135°. 4-Ac deriv. (V) of III, m. 165° (decompn.). VII, m. 112°. VIII, m. 164°. C. A. R.

**Commercial method of preparation of pyridine bases.** N. Narushkin, E. Chernomordik and A. Kvasnitski. *Coke and Chem.* (U. S. S. R.) 1932, No. 5 6, 52 68. A review of plant processes for the recovery of pyridine bases from benzene. The Glund-Schneider recovery scheme is considered unsuitable for U. S. S. R. industry. Washing of the benzene followed by dephenolation is recommended. James Sorrel

**Oxidation of pyridine to a 2-pyridylpyridinium salt.** Paul Baumgarten and Else Dammann. *Ber.* 66B, 1633 8(1933). All previous attempts to oxidize pyridine with peracids had resulted either in the formation of pyridine N-oxide (with  $BrO_3H$ ; Meisenheimer, C. A. 21, 94) or in complete oxidative degradation (with persulfate; Dorronsoro, C. A. 22, 783). Under the conditions described in this paper (heating aq. pyridine with  $K_2S_2O_8$  1–2 hrs.) the oxidation followed a different course; the chief product was 2-pyridylpyridinium sulfate which, however, could not be isolated but, after removal of the  $H_2SO_4$  and excess of pyridine, was converted into the perchlorate (I), m. 214°. The reaction apparently consists in dehydrogenation of a pyridinium ion in the 1-position and of a 2nd mol. in the 2-position, and combination of the resulting residues. The intermediate formation of pyridine N-oxide is excluded by the fact that these salts cannot be obtained from the N-oxide and pyridine I in water with excess of  $NaOH$  or  $KOH$  gives an intensely yellow-red soln. which with  $HCl$  and  $PhNH_2$   $HCl$  yields  $PhNHCH:CHCH:CHCH:NPh$   $HCl$  (II) and 2-aminopyridine. Koenigs and Gräner's 4-pyridylpyridinium dichloride behaves in the same way with alkalis (C. A. 25, 3998), but whereas the base of this salt is normally diacidic, the 2-pyridyl base is mono-
